Taxation.—The total valuation of land in 1900 was $171,527,025, or $6.61 an acre; the total valuation of town lots was $120,338,355, and of other property, $48,493,768; or, adding the railway, telegraph, and telephone property, the total valuation of all taxable real property is $387,050,050. The rate of taxation for state purposes is 35 cents per $100. Real property bears nearly the entire burden of taxation. In 1899, when the assessed value of real property (excluding railways) was $271,021,726, the assessed valuation of personal property, excluding railway property, was only $37,693,230, or 12 2 per cent. of the whole. The ratio in neighbouring states with similar industries ran from 30 to 50 per cent., showing that 15 to 30 per cent. of personal property escaped. The state tax on real property yielded in 1900, net, $1,022,029. Clerks of courts paid in certain fees, which brought the total returns from counties up to $1,556,989. Many privileges are taxed, amounting in 1900 to $417,199. Other sources of state revenue are: fees for charters, building and loan associations, insurance, and coal oil inspection. The total receipts for 1900 were $6,120,231; total disbursements, $6,095,299. The total bonded indebtedness is $16,953,266. Since 1899 10 per cent. of the gross receipts is carried to a sinking fund.

Miscellaneous —There were 207 banks in 1900—national 48, state and private 159—with a total paid-up capital and surplus of $17,370,662, and deposits of $45,686,251. The number of newspapers and periodicals was 306. There are 27 cotton and 21 woollen-mills The value of the annual production of flour is $13,000,000, of lumber $6,000,000, of leather $2,400,000; of cottonseed oil there are produced 3,200,000 gallons, and of distilled spirits 1,100,000 gallons. The largest churches are the following: the Methodist Episcopal Church South has 132,000 members; the Baptist has 115,000 white members, 62,000 coloured members; Cumberland Presbyterian, 43,000; Presbyterian, 18,300; Roman Catholic, 18,000; and Protestant Episcopal, 6000 members.

Agriculture.—Possessing many kinds of soils, spread out at all altitudes from 6000 feet down to 300 feet above sea-level, with a climate varying from the semi-tropical on the Mississippi river in the west, to the boreal on the mountain plateaus of the east, Tennessee has the greatest variety of agricultural and horticultural products. It has something in every column of the census of agriculture. Wheat, oats, rye, and barley mature well in the valleys of the eastern and central districts; maize is a great crop in all parts; tobacco is produced in nearly all quarters; and cotton is at home in the south-western corner of the state. Potatoes, sorghum, broom-corn, and peanuts are important crops also in the middle and west. Small fruits and vegetables are produced in large quantities for the great cities. The eastern section is well adapted to large fruits, and the grape does well all over the state. Nutritious grasses grow well, and stock-raising and dairying are great industries in the central and eastern portion. The following table shows the acreage, production and value of the principal crops in 1899:—

	Acreage.	Production.	Farm Value.
	Acres.	Bushels.	Dollars.
Corn (maize) .	3,374,574	67,307,390	28,059,508
Wheat . .	1,426,112	11,924,010	7,882,697
Oats . .	235,313	2,725,330	887,940
Potatoes . .	27,103	1,404,097	817,419
Sweet potatoes	23,374	1,571,575	883,620
Orchard fruits	208,625	...	1,479,915
Hay . .	645,617	802,720 (tons)	6,811,577
Cotton . .	623,137	234,592 (bales)	8,192,642
Tobacco . .	71,849	49,157,550 (lb)	2,748,495

In 1899 Tennessee had 309,000 horses, of an average value of $43 per head; 140,000 mules, of an average value of $48; 240,000 milch cows, of an average value of $24; 287,000 other cattle, of an average value of $19; and 252,000 sheep, of an average value of $2.37. The poultry industry is a considerable one in the central and eastern parts.

Mining.—The chief mineral productions in 1900 were coal, 3,904,048 short tons; coke, 494,438 short tons; iron ore, 700,000 long tons; copper, 116,000 long tons; and zinc, 3968 short tons. Phosphate mining is a new and great industry in middle Tennessee. In 1900 450,556 short tons of phosphate were produced, valued at $1,352,568 at the mines. The total number of persons employed in mining industries was in 1900 as follows: in coal mining 9181, in iron ore mining 1082, in copper mining and smelting 886, in phosphate mining 3000. Including some other small mines, the total was 15,000.

Administration.—The state government has the usual departments, legislative, executive, and judicial. The legislature has two chambers, the house and the senate; its members are elected for two years, and their sessions are limited to ninety days. The governor is elected for two years. In case of vacancy the speaker of the senate succeeds him. The legislature elects the secretary of state, the comptroller, and the treasurer; the governor appoints, subject to confirmation by the senate, the superintendent of public instruction, the superintendent of prisons, the commissioner of agriculture, and the commissioner of labour and mines. The Supreme Court consists of five judges, elected for eight years. There are also chancery courts, circuit courts, and a court of chancery appeals. The large counties have separate criminal courts. The affairs of the counties are administered by the justices of the peace, elected two or more from each civil district, which is the smallest unit of government. The magistrates have both legislative and judicial powers. Each county has a sheriff, a trustee (collector of taxes and treasurer), a register, and clerks of courts. Towns and cities are incorporated by special Act of the legislature, and usually have a mayor and common council, with the ordinary municipal offices. Suffrage is free to male citizens of the United States who have been one year in the state and six months in the county. The Australian ballot system is in use in the larger towns and counties.

Political Changes.—During the last part of the decade from 1880 to 1890 an agrarian movement swept over the southern and western states, resulting in the organization of farmers in various societies called "granges," "wheels," &c., which were finally all united in a national "Farmers' Alliance." These organizations were naturally strong in Tennessee, an agricultural state, and for a time exerted a great influence in politics. They captured the Democratic party, which of recent years has controlled the state, and elected their nominee for governor in 1890 upon a platform which proposed many changes looking to the restriction of the business of the professional and commercial classes, especially the so-called "middlemen" who dealt in agricultural products or supplies, and to the advancement of the agricultural industries. The new governor was a farmer and the leading spirit in the Alliance, but his constituents were disappointed in their expectation of unreasonable and impossible changes. The most serious event during this administration was a miners' war, which grew out of the penitentiary lease system. Tennessee had had the lease system since 1867. The able-bodied convicts, a large majority of whom were young negro men, were leased to companies, who used them in manufacturing shoes and waggons, and in working marble quarries and coal mines. Under this system the people were relieved of the burden of supporting the convicts, who were made to bring the state a revenue of more than one hundred thousand dollars a year. Great discontent grew up, however, among the labourers, especially the miners. Free men could not get work at the coal mines, and the people living in the mining districts objected to having large bodies of convicts among them. The trouble began in July 1891, and continued at intervals until the autumn of 1892. The miners attacked the prisons and set the convicts at liberty at many places. They openly defied state authorities, and overpowered the first militia that was sent against them. The authorities did not get control until a considerable force of reorganized militia had been put in the field. Judge Peter Turney, an old-time Democrat, chief justice of the Supreme Court of the state, was nominated by the Democrats and elected governor in 1892 as a protest against the rather weak measures of the state government in the miners' war. These disturbances were soon brought to an end. Governor Turney advocated the abolition of the penitentiary lease system, the erection of a new large penitentiary, and the working of convicts in coal mines owned by the state. These measures were all carried out. Convicts are employed in various manufactures in the prison, in raising field and garden crops for their own use, and the more able-bodied ones are utilized in mining coal, upon property owned by the state, to be used in the capitol, asylums, and other state institutions. Governor Turney was a candidate for re-election in 1894, and the Republicans nominated Mr H. Clay Evans. At the close of the election both candidates claimed the office. The matter was carried before the legislature for investigation and settlement, and resulted in a bitter contest. The laws of Tennessee require that every citizen between 21 and 50 years of age shall pay a poll-tax every year or forfeit his right to vote. The legislative investigation showed that many men had voted who had not paid their poll-tax, and that in counties where this occurred Mr Evans had received his largest majorities. He was therefore declared not legally elected, and Governor Turney was inaugurated and served the full term. The chief legislative act of later years was the adoption of a "uniform text-book law," which provided a commission to select text-books to be used in the public schools and to make contracts with publishers for supplying them at moderate and uniform prices. This Act went into effect 1st July 1899, with a contract which was to continue in force for a period of five years. (C. W. D.)

Tennessee River, the longest and most important branch of Ohio river, U.S.A. It takes its source in numerous streams in the Appalachian valley in south-western Virginia and east Tennessee, and in the mountains of western North Carolina. Among these head-waters are the Holston, Clinch, and Powell rivers of east Tennessee and the Nolichucky, Big Pigeon, French Broad, and Little Tennessee of North Carolina. The Tennessee is popularly regarded as commencing at the junction of the Holston and French Broad, near Knoxville, Tennessee. Thence it flows south-westwards through the Appalachian valley into Alabama, where it turns to west-north-west and, just touching Mississippi, returns into Tennessee. It crosses that state and also Kentucky, flowing nearly north to its mouth at Paducah. Its length from its mouth to Knoxville is 639 miles, and, following up the Holston to its source, 782 miles. Its drainage basin comprises 43,897 square miles. It is navigable from its mouth to Muscle Shoals in Alabama, and thence, by slack water navigation, to Knoxville.

Tenniel, Sir John (1820–——), English humorous and satirical artist—specially identified with *Punch*—was born in London in 1820. He educated himself for his career, and although he became a probationer, and then a student, of the Royal Academy, he soon left the schools, where at that time there was little teaching. In 1836 he sent his first picture to the exhibition of the Society of British Artists, and in 1845 contributed a 16-feet cartoon, "An Allegory of Justice," to the competition, held in that year, of designs for the mural decoration of the new Palace of Westminster. For this he received a £200 premium and a commission to paint a fresco in the Upper Waiting Hall (or "Hall of Poets") in the House of Lords. In spite of his tendency towards "high art," he was already known and appreciated as a humorist, and his early companionship with Charles Keene fostered and developed his talent for scholarly caricature. At Christmas time 1850 he was invited by Mark Lemon to fill the position of joint cartoonist (with John Leech) on *Punch*, from which Richard Doyle, offended by the attitude adopted by the paper towards the Papal see at the time of the so-called "aggression," had suddenly resigned. On the strength of his remarkable illustrations to Æsop's Fables, in which artistic power, humour of observation, and knowledge of animal life were equally apparent, Tenniel was selected, on Dougla

"DROPPING THE PILOT." By SIR JOHN TENNIEL.

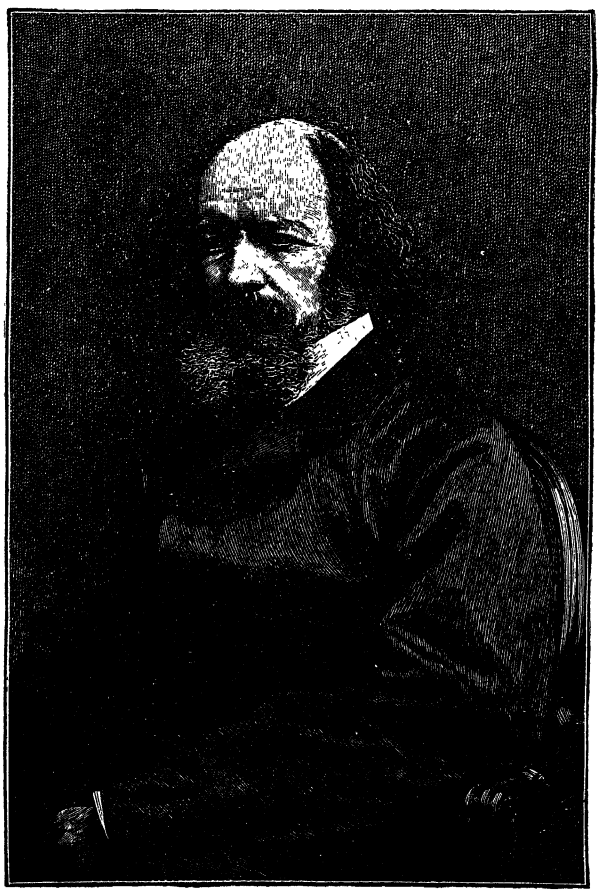
(By permission of the Proprietors of "Punch.")

Jerrold's initiative, to fill the breach, and he contributed his first drawing in the initial letter appearing on p. 224, vol. xix. His first "cartoon" was "Lord Jack the Giant Killer": it showed Lord John Russell, whose letter on the "aggression" had recently been published, valiantly assailing with the sword of truth and liberty Cardinal Wiseman, armed with a crozier. In 1852 we have Tenniel's first superb lion, and his first obituary cartoon (*q.v.* under CARICATURE). Gradually he took over altogether the weekly drawing of the political "big cut," which John Leech was happy to resign into his hands in order to restrict himself to his pictures of life and character. Leech's work consisted for the most part of farce; Tenniel's was high comedy, and not infrequently tragedy; and the freedom of the humorist heightened the severer beauties of the satirist. When Leech died his friend continued his work alone, and except in 1864, 1868, and 1875–6–7–8, during short spells of illness or holiday, he did not miss a single week. About 2300 cartoons, innumerable minor drawings, double-page cartoons for *Punch's Almanac* and other special numbers, and 250 designs for *Punch's Pocket-books*, comprise the sum of Sir John Tenniel's work for the periodical in the service of which he spent the greater portion of his life. When Tenniel retired from the service of *Punch* in January 1901 he received the honour of a farewell banquet (12th June), at which Mr A. J. Balfour, then leader of the House of Commons, presided and was supported by distinguished representatives of all that was best in English life. On that occasion Mr Balfour's description of Tenniel as "a great artist and a great gentleman" was applauded by the press of the whole country.

The main quality of Sir John Tenniel's work is accuracy of drawing, precision of touch, grace and dignity of conception, and —so far as such things can be compatible—geniality of satire. Tenniel raised the political cartoon into a classic composition, from which a sense of nobility is rarely absent. The beauty and statuesqueness of his ideal figures recall the influence, perhaps, of Cornelius and Overbeck—that German manner which was characteristic of many of our finer draughtsmen upon wood at the middle of the 19th century. But Tenniel's work is always original, unforced, and fresh; and it never suggests, what is the fact, that the artist's work is drawn exclusively from memory, and never from the model. It may be mentioned that Tenniel's wonderful observation has been conducted, and his knowledge accumulated, literally through a single eye, the other having been lost during a fencing bout in his youth. It was in recognition not only of his ability as an artist in black and white, but of his service in infusing good humour and good taste into one phase of political life, that a knighthood was conferred upon him on Mr Gladstone's recommendation in 1893. Without pronounced political opinions of his own, Sir John Tenniel adopted in his work those of his paper, of which the Whig proclivities were to some degree softened by his pencil. The political history not of England only, but to some extent of the world, of half a century appears in Sir John Tenniel's weekly cartoons, which are dignified by a number of types invented by the artist, the classic beauty of which may be looked for in vain in kindred work by any previous cartoonist. (Take, for example, Sir John's famous picture of "Dropping the Pilot" [see Plate], which appeared in *Punch* on 20th March 1890, vol. xcviii. pp. 150–51.) Two public exhibitions of Sir John Tenniel's work have been held, one in 1895 and the other in 1900. Sir John Tenniel is also the author of one of the mosaics, "Leonardo da Vinci," in the South Court in the Victoria and Albert Museum; while his highly stippled water-colour drawings have appeared from time to time in the exhibitions of the Royal Institute of Painters in Water Colours, of which society he was elected a member in 1874. As an illustrator on the wood-block he stands very high; his "Lalla Rookh" is perhaps the finest of all his work in point of conception, refinement, power, and technical excellence.

WORKS ILLUSTRATED.—(1) *Juvenile Verse and Picture Book*, 1846; (2) *Undine*, 1846; (3) *Æsop's Fables*, 100 drawings, 1848; (4) Blair's *Grave*, 1858; (5) Shirley Brooks's *The Gordian Knot*, 1860, and (6) *The Silver Cord*, 1861; (7) Moore's *Lalla Rookh*, 69 drawings, 1861; (8) Lewis Carroll's *Alice's Adventures in Wonderland*, 1866; (9) *The Mirage of Life*, 1867; (10) Carroll's *Through the Looking-Glass*, 1870; and the following in collaboration: (11) Pollok's *Course of Time*, 1857; (12) *Poets of the Nineteenth Century*, 1857; (13) Poe's Works, 1857; (14) *Home Affections*, 1858; (15) Cholmondeley Pennell's *Puck on Pegasus*, 1863; (16) *The Arabian Nights*, 1863; (17) *English Sacred Poetry*, 1864; (18) *Legends and Lyrics*, 1865; (19) Tupper's *Proverbial Philosophy*; (20) Barry Cornwall's *Poems*, and other books. He also contributed to *Once a Week*, the Art Union publications, &c.

Tennyson, Alfred Tennyson, 1st BARON (1809–1892), English poet, was the fourth of the twelve children of the Rev. George Clayton Tennyson (1778–1831) and his wife Elizabeth Fytche (1781–1865). The Tennysons were an old Lincolnshire family settled at Bayou's Manor, where the poet's grandfather, Mr George Tennyson, M.P., resided, while the father was settled hard by in the rectory of Somersby. Here Alfred was born on the 6th of August 1809. The rich pastoral scenery of this part of Lincolnshire influenced the imagination of the boy, and is plainly reflected in all his early poetry, although it is now stated with authority that the localities of his subject-poems, which had been ingeniously identified with real brooks and granges, were wholly imaginary. At a very early age he began to write in prose and verse. At Christmas 1815 he was sent to the grammar school at Louth, his mother having kept up a connexion with this typical Lincolnshire borough, of which her father, the Rev. Stephen Fytche, had been vicar. Tennyson was at this school for five years, and then returned to Somersby to be trained by his father. In the rectory the boys had the run of an excellent library, and here the young poet based his wide knowledge of the English classics. The news of Byron's death (19th April 1824) made a deep impression on him: it was a day, he said, "when the whole world seemed to be darkened for me"; he went out into the woods and carved "Byron is dead" upon a rock. Tennyson was already writing copiously—"an epic of 6000 lines" at twelve, a drama in blank verse at fourteen, and so on: these exercises have, very properly, not been printed, but the poet said of them at the close of his life, "It seems to me, I wrote them all in perfect metre." The family was in the habit of spending the summer holidays at the coast of the county, commonly at Mablethorpe, and here Tennyson gained his impressions of the vastness of the sea. FitzGerald very justly attributed the landscape character of Tennyson's genius to the impress left on his imagination by "old Lincolnshire, where there were not only such good seas, but also such fine hill and dale among the wolds."



In 1827 Frederick Tennyson (1807–1898), the eldest surviving brother, uniting with his younger brothers Charles (1808–1879) and Alfred, published at Louth an anonymous collection of *Poems by Two Brothers*. The "two" were Charles and Alfred (whose contributions predominated), and who shared the surprising profits, £20. On the 20th February 1828 Charles and Alfred matriculated at Trinity College, Cambridge, where Frederick was already a scholar. The poet told the writer of these lines that his father would not let him leave Somersby till, on successive days, he had recited from memory the whole of the odes of Horace. The brothers took rooms at 12 Rose Crescent, and afterwards moved into Trumpington Street (now 157 Corpus Buildings). They were shy, and made at first few friends; but they gradually gathered selected associates around them, and Alfred grew to be looked up to at Cambridge "as to a great poet and an elder brother" by a group which included Trench, Monckton Milnes, Spedding, Thompson, FitzGerald, Brookfield, and, most of all, A. H. Hallam (1811–1833). In June 1829 Tennyson won the Chancellor's prize medal for his poem called "Timbuctoo." With great imperfections, this study in Miltonic blank verse displays the genius of a poet, in spite of a curious obscurity both of thought and style. Here are already

both richness and power, although their expression is not yet clarified by taste. But by this time Tennyson was writing lyrics of still higher promise, and, as Arthur Hallam early perceived, with an extraordinary earnestness in the worship of beauty. The results of this enthusiasm and this labour of the artist appeared in the volume of *Poems, chiefly Lyrical*, published in 1830. This book would have been astonishing as the production of a youth of twenty-one, even if, since the death of Byron six years before, there had not been a singular dearth of good poetry in England. Here at least, in the slender volume of 1830, was a new writer revealed, and in "Mariana," "The Poet," "Love and Death," and "Oriana," a singer of wonderful though still unchastened melody. Through these, and through less perfect examples, was exhibited an amazing magnificence of fancy, at present insufficiently under control, and a voluptuous pomp of imagery, tending to an over-sweetness. The veteran S. T. Coleridge, praising the genius in the book, blamed the metrical imperfection of it. For this criticism he has himself constantly been reproved, and Tennyson (whose impatience of anything like censure was phenomenal) continued to resent it to the end of his life. Yet Coleridge was perfectly just in his remark; and the metrical anarchy of the "Madelines" and "Adelines" of the 1830 volume showed that Tennyson, with all his delicacy of modulation, had not yet mastered the arts of verse.

In the summer of 1830 Tennyson and Hallam volunteered in the army of the Spanish insurgent Torrijos, and marched about a little in the Pyrenees, without meeting with an enemy. He came back to find his father ailing, and in February 1831 he left Cambridge for Somersby, where a few days later Dr George Tennyson died. The new incumbent was willing that the Tennysons should continue to live in the rectory, out of which they did not turn until six years later. Arthur Hallam was now betrothed to Emily Tennyson (afterwards Mrs Jesse, 1811–1889), and stayed frequently at Somersby. This was a very happy time, and one of great physical development on Alfred's part. He took his share in all kinds of athletic exercises, and it was now that Brookfield said, "It is not fair that you should be Hercules as well as Apollo." This high physical zest in life seems to have declined after 1831, when his eyes began to trouble him, and he became liable to depression. The poetical work of these three years, mainly spent at Somersby, was given to the world in the volume of *Poems* which appeared at the end of 1832. This was one of the most astonishing revelations of finished genius ever produced, certainly by a young man of less than four-and-twenty. Here were to be read "The Lady of Shalott," "The Dream of Fair Women," "Œnone," "The Lotos-Eaters," "The Palace of Art," and "The Miller's Daughter," with a score of other lyrics, delicious and divine. The advance in craftsmanship and command over the *matériel* of verse shown since the volume of 1830 is absolutely astounding. If Tennyson had died of the savage article which presently appeared in the *Quarterly Review*, literature would have sustained terrible losses, but his name would have lived for ever among those of the great English poets. Indeed, it may be doubted whether, in several directions, he ever surpassed the glorious things to be found in this most exquisite and most precious book. It was well that its publication was completed before the blow fell upon Tennyson which took for a while all the light out of his life. In August 1833 Arthur Hallam started with his father, the great historian, for Tirol. They went no farther than Vienna, where Mr Hallam, returning to the hotel on the 15th September 1833, found his son lying dead on a sofa: a blood-vessel had broken in his brain. His body was brought back to England, and buried at Clevedon on the 3rd January 1834. These events affected Tennyson extremely. He grew less than ever willing to come forward and face the world; his health became "variable and his spirits indifferent." The earliest effect of Hallam's death upon his friend's art was the composition, in the summer of 1834, of *The Two Voices;* and to the same period belong the beginnings of the *Idylls of the King* and of *In Memoriam*, over both of which he meditated long. In 1835 he visited the Lakes, and saw much of Hartley Coleridge, but would not "obtrude on the great man at Rydal," although "Wordsworth was hospitably disposed." Careless alike of fame and of influence, Tennyson spent these years mainly at Somersby, in a uniform devotion of his whole soul to the art of poetry. In 1837, to their great distress, the Tennysons were turned out of the Lincolnshire rectory where they had lived so long. They moved to High Beech, in Epping Forest, which was their home until 1840. The poet was already engaged, or "quasi-betrothed," to Emily Sellwood, but ten years more had to pass before they could afford to marry. At Torquay, in 1838, he wrote *Audley Court* on one of his rare excursions, for he had no money for touring, nor did he wish for change: he wrote at this time, "I require quiet, and myself to myself, more than any man when I write." In 1840 the Tennysons moved to Tunbridge Wells, and a year later to Boxley, near Maidstone, to be close to Edmund Lushington, who had now married Cecilia Tennyson. Alfred was from this time more and more frequently a visitor in London.

In 1842 the two-volumes edition of his *Poems* broke the ten years' silence which he had enforced himself to keep. Here, with many pieces already known to all lovers of modern verse, were found rich and copious additions to his work. These he had originally intended to publish alone, and an earlier privately-printed *Morte d'Arthur, Dora, and other Idylls*, of 1842, is the despair of book-collectors. Most of those studies of home-life in England, which formed so highly popular a section of Tennyson's work—such as "The Gardener's Daughter," "Walking to the Mail," and "The Lord of Burleigh"—were now first issued, and, in what we have grown to consider a much higher order, "Locksley Hall," "Ulysses," and "Sir Galahad." To the older and more luxurious lyrics, as reprinted in 1842, Tennyson did not spare the curbing and pruning hand, and in some cases went too far in restraining the wanton spirit of beauty in its youthful impulse. It is from 1842 that the universal fame of Tennyson must be dated; from the time of the publication of the two volumes he ceased to be a curiosity, or the darling of an advanced clique, and took his place as the leading poet of his age in England. Among the friends whom he now made, or for the first time cultivated, were Carlyle, Rogers, Dickens, and Elizabeth Barrett. Material difficulties now, however, for the first time intruded on his path. He became the victim of a certain "earnest-frothy" speculator, who induced him to sell his little Lincolnshire estate at Grasby, and to invest the proceeds, with all his other money, and part of that of his brothers and sisters, in a "Patent Decorative Carving Company": in a few months the whole scheme collapsed, and Tennyson was left penniless. He was attacked by so overwhelming a hypochondria that his life was despaired of, and he was placed for some time under the charge of a hydropathic physician at Cheltenham, where absolute rest and isolation gradually brought him round to health again. The state of utter indigence to which Tennyson was reduced greatly exercised his friends, and in September 1845, at the suggestion of Henry Hallam, Sir Robert Peel was induced to bestow on the poet a pension of £200 a year. Never was public money expended in a more

patriotic fashion. Tennyson's health slowly became restored, and in 1846 he was hard at work on *The Princess;* in the autumn of this year he took a tour in Switzerland, and saw great mountains and such "stateliest bits of landskip" for the first time. In 1847 nervous prostration again obliged him to undergo treatment at Prestbury: "They tell me not to read, not to think; but they might as well tell me not to live." Dr Gully's water-cure was tried, with success. *The Princess* was now published, in a form afterwards considerably modified and added to. Carlyle and FitzGerald "gave up all hopes of him after *The Princess*," or pretended that they did. It was true that the bent of his genius was slightly altered, in a direction which seemed less purely and austerely that of the highest art; but his concessions to public taste vastly added to the width of the circle he now addressed. The home of the Tennysons was now at Cheltenham: on his occasional visits to London he was in the habit of seeing Thackeray, Coventry Patmore, Browning, and Macready, as well as older friends, but he avoided "society." In 1848, while making a tour in Cornwall, Tennyson met Hawker of Morwenstow, with whom he seems—but the evidence is uncertain—to have talked about King Arthur, and to have resumed his intention of writing an epic on that theme. In his absent-minded way Tennyson was very apt to mislay objects; in earlier life he had lost the MS. of *Poems, chiefly Lyrical*, and had been obliged to restore the whole from scraps and memory. Now a worse thing befell him, for in February 1850, having collected into one "long ledger-like book" all the elegies on Arthur Hallam which he had been composing at intervals since 1833, he left this only MS. in the cupboard of some lodgings in Mornington Place, Hampstead Road. By extraordinary good chance it had been overlooked by the landlady, and Coventry Patmore was able to recover it. In this way *In Memoriam* was dragged back from the very verge of destruction, and could be published, in its original anonymous form, in May 1850. The public was at first greatly mystified by the nature and object of this poem, which was not merely a chronicle of Tennyson's emotions under bereavement, nor even a statement of his philosophical and religious beliefs, but, as he long afterwards explained, a sort of *Divina Commedia*, ending with happiness in the marriage of his youngest sister, Cecilia Lushington. In fact, the great blemishes of *In Memoriam*, its redundancy and the dislocation of its parts, were largely due to the desultory manner of its composition. The poet wrote the sections as they occurred to him, and did not think of weaving them together into a single poem until it was too late to give them real coherency. The metre, which by a curious naïveté Tennyson long believed that he had invented, served by its happy peculiarity to bind the sections together, and even to give an illusion of connected movement to the thought.

ALFRED TENNYSON.
(From a photograph by Elliott and Fry, London.)

The sale of Tennyson's poems now made it safe for him to settle, and on the 13th June 1850 he was married at Shiplake to Emily Sarah Sellwood (1813–1896). Of this union no more need be said than was recorded long afterwards by the poet himself, "The peace of God came into my life before the altar when I wedded her." Every species of good fortune was now to descend on the path of the man who had struggled against ill luck so long. Wordsworth died, and on the 19th November 1850 Queen Victoria appointed Tennyson Poet Laureate. The salary connected with the post was very small, but it had a secondary value in greatly stimulating the sale of his books, which was his main source of income. The young couple took a house at Warninglid, in Sussex, which did not suit them, and then one in Montpelier Row, Twickenham, which did better. In April 1851 their first child was born dead. At this time Tennyson was brooding much upon the ancient world, and reading little but Milton, Homer, and Virgil. This condition was elegantly defined by Carlyle as "sitting on a dungheap among innumerable dead dogs." In the summer of 1851 was made the tour in Italy, of which *The Daisy* is the immortal record. Of 1852 the principal events were the birth of his eldest son, the second Lord Tennyson, in August, and in November the publication of the *Ode on the Death of the Duke of Wellington*. In the winter of 1853 Tennyson entered into possession of a little house and farm called Farringford, near Freshwater, in the Isle of Wight, which he leased at first, and afterwards bought: this beautiful place, ringed round with ilexes and cedars, entered into his life and coloured it with its delicate enchantment. In 1854 he published *The Charge of the Light Brigade*, and was busy composing *Maud* and its accompanying lyrics; and this volume was published in July 1855, just after he was made D.C.L. at Oxford: he was received on this occasion, which may be considered his first public appearance, with a "tremendous ovation." The reception of *Maud* from the critics, however, was the worst trial to his equanimity which Tennyson had ever had to endure, nor had the future anything like it in store for him. He had risen in *Maud* far above his ordinary serenity of style, to ecstasies of passion and audacities of expression which were scarcely intelligible to his readers, and certainly not welcome. It is odd that this irregular poem, with its copious and varied music, its

splendid sweep of emotion, its unfailing richness of texture—this poem in which Tennyson rises to heights of human sympathy and intuition which he reached nowhere else, should have been received with bitter hostility, have been styled "the dead level of prose run mad," and have been reproved more absurdly still for its "rampant and rabid bloodthirstiness of soul." There came a reaction of taste and sense, but the delicate spirit of Tennyson had been wounded. For some years the world heard nothing from him; he was at Farringford, busying himself with the Arthurian traditions. He had now become an object of boundless personal curiosity, being already difficult to find, and the centre of amusing legends. It was in 1857 that Bayard Taylor saw him, and carried away the impression of a man, "tall and broad-shouldered as a son of Anak, with hair, beard, and eyes of southern darkness." This period of somewhat mysterious withdrawal from the world embraced a tour in Wales in 1857, a visit to Norway in 1858, and a journey through Portugal in 1859. In 1857 two Arthurian poems had been tentatively and privately printed, as *Enid and Nimue, or the True and the False*, to see how the idyllic form would be liked by the inner circle of Tennyson's friends. In the summer of 1859 the first series of *Idylls of the King* was at length given to the world, and achieved a popular success far beyond anything experienced before by any English poets, save perhaps Byron and Scott. Within a month of publication, 10,000 copies had been sold. The idyls were four in number, "Enid," "Vivien" (no longer called "Nimue"), "Elaine," and "Guinevere." These were fragments of the epic of the fall of King Arthur and the Table Round which Tennyson was so long preparing, and which he can hardly be said to have ever completed, although nearly thirty years later he closed it. The public and the critics alike were entranced with the "sweetness" and the "purity" of the treatment. A few, like Ruskin, were doubtful about "that increased quietness of style"; one or two already suspected that the "sweetness" was obtained at some sacrifice of force, and that the "purity" involved a concession to Victorian conventionality. It was not perceived at the time that the four idyls were parts of a great historical or mystical poem, and they were welcomed as four polished studies of typical women: it must be confessed that in this light their even perfection of workmanship appeared to greater advantage than it eventually did in the general texture of the so-called "epic." In 1859 "Boadicea" was written, and "Riflemen, Form!" published in *The Times*. Urged by the Duke of Argyll, Tennyson now turned his attention to the theme of the Holy Grail, though he progressed with it but fitfully and slowly. In 1861 he travelled in Auvergne and the Pyrenees, with Clough, who was to die a few months later; to this year belong "Helen's Tower" and the "Dedication" of the *Idylls* to the Prince Consort, "These to his Memory." The latter led to Tennyson's presentation in April 1862 to the Queen, who "stood pale and statue-like before him, in a kind of stately innocence," which greatly moved his admiring homage. From this time forth the poet enjoyed the constant favour of the Sovereign, though he could never be moulded into a conventional courtier. He now put the Arthurian legends aside for a time, and devoted himself to the composition, in 1862, of "Enoch Arden," which, however, did not appear until 1864, and then in a volume which also contained "Sea Dreams," "Aylmer's Field," and, above all, "The Northern Farmer," the first and finest of Tennyson's remarkable studies in dialect. In April of this year Garibaldi visited Farringford; in February 1865 Tennyson's mother died at Hampstead in her eighty-fifth year; in the ensuing summer he travelled in Germany. The time slipped by with incidents but few and slight, Tennyson's popularity in Great Britain growing all the time to an extent unparalleled in the whole annals of English poetry. This universality of fame led to considerable practical discomfort; he was besieged by sight-seers, and his nervous trepidation led him perhaps to exaggerate the intensity of the infliction. In 1867 he determined to make for himself a haven of refuge against the invading Philistine, and bought some land on Blackdown, above Haslemere, then a remote corner of England; here Mr James Knowles began to build him a house, ultimately named Aldworth. This is the time of two of his rare, privately printed pamphlets, *The Window; or, the Loves of the Wrens* (1867), and *The Victim* (1868). The noble poem *Lucretius*, one of the greatest of Tennyson's versified monographs, appeared in May 1868, and in this year *The Holy Grail* was at last finished; it was published in 1869, together with three other idyls belonging to the Arthurian epic, and various miscellaneous lyrics, besides *Lucretius*. The reception of this volume was cordial, but not so universally respectful as Tennyson had grown to expect from his adoring public. The fact was that the heightened reputation of Browning, and still more the sudden vogue of Swinburne, Morris, and Rossetti (1866–1870), considerably disturbed the minds of Tennyson's most ardent readers, and exposed himself to a severer criticism than he had lately been accustomed to endure. He went on quite calmly, however, sure of his mission and of his music. His next volume (1872), *Gareth and Lynette* and *The Last Tournament*, continued and, as he then supposed, concluded *The Idylls of the King*, to the great satisfaction of the poet, who had found much difficulty in rounding off the last sections of the poem. Nor, as he was to find, was the poem yet completed, but for the time being he dismissed it from his mind. In 1873 he was offered a baronetcy by Gladstone, and again by Disraeli in 1874; in each case the honour was gracefully declined. Believing that his work with the romantic Arthurian epics was concluded, Tennyson now turned his attention to a department of poetry which had long attracted him, but which he had never seriously attempted—the drama. He put before him a scheme, which he cannot be said to have carried far, that of illustrating "the making of England" by a series of great historical tragedies. His *Queen Mary*, the first of these chronicle-plays, was published in 1875, and played by Mr Irving at the Lyceum in 1876. Although it was full of admirably dramatic writing, it was not theatrically well composed, and it failed on the stage. Extremely pertinacious in this respect, the poet went on attempting to storm the theatre, with assault upon assault, all practically failures until the seventh and last, which was unfortunately posthumous. To have really succeeded on the stage would have given Tennyson more gratification than anything else, but he was not permitted to live long enough to see this blossom also added to the heavy garland of his glory. Meanwhile *Harold*, a tragedy of doom, was published in 1876; but, though perhaps the finest of its author's dramas, it has never been acted. During these years Tennyson's thoughts were largely occupied with the building of Aldworth. His few lyrics were spirited ballads of adventure, inspired by an exalted patriotism—"The Revenge" (1878), "The Defence of Lucknow" (1879)—but he reprinted and finally published his old suppressed poem, *The Lover's Tale*, and a little play of his, *The Falcon*, versified out of Boccaccio, was produced by the Kendals at their theatre in the last days of 1879. Tennyson had reached the limits of the threescore years and ten, and it was tacitly taken for granted that he would now retire into dignified repose. In point of fact, he now started on a new lease of poetical activity.

In 1880 he published the earliest of six important collections of lyrics, this being entitled *Ballads and other Poems*, and containing the sombre and magnificent "Rizpah." In 1881 *The Cup* and in 1882 *The Promise of May*, two little plays, were produced without substantial success in London theatres: the second of these is perhaps the least successful of all the poet's longer writings, but its failure annoyed him unreasonably. This determination to be a working playwright, pushed on in the face of critical hostility and popular indifference, is a very curious trait in the character of Tennyson. In September 1883 Tennyson and Gladstone set out on a voyage round the north of Scotland, to Orkney, and across the ocean to Norway and Denmark. At Copenhagen they were entertained by the king and queen, and after much fêting, returned to Gravesend: this adventure served to cheer the poet, who had been in low spirits since the death of his favourite brother Charles, and who now entered upon a phase of admirable vigour. During the voyage Gladstone had determined to offer Tennyson a peerage. After some demur, the poet consented to accept it, but added, "For my own part, I shall regret my simple name all my life." On the 11th March 1884 he took his seat in the House of Lords as Baron Tennyson of Aldworth and Farringford. He voted twice, but never spoke in the House. In the autumn of this year his tragedy of *Becket* was published, but the poet at last despaired of the stage, and disclaimed any hope of "meeting the exigencies of our modern theatre." Curiously enough, after his death *Becket* was the one of all his plays which enjoyed a great success on the boards. In 1885 was published another interesting miscellany, *Tiresias and other Poems*, with a posthumous dedication to Edward FitzGerald. In this volume, it should be noted, *The Idylls of the King* was completed at last by the publication of "Balin and Balan"; it contained also the superb address "To Virgil." In April 1886 Tennyson suffered the loss of his second son, Lionel, who died in the Red Sea on his return from India. The untiring old poet was steadily writing on, and by 1886 he had another collection of lyrics ready, *Locksley Hall Sixty Years After*, &c.; his eyes troubled him, but his memory and his intellectual curiosity were as vivid as ever. Late in 1888 he had a dangerous attack of rheumatic gout, from which it seemed in December that he could scarcely hope to rally, but his magnificent constitution pulled him through. He was past eighty when he published the collection of new verses entitled *Demeter and other Poems* (1889), which appeared almost simultaneously with the death of Browning, an event which left Tennyson a solitary figure indeed in poetic literature. In 1891 it was observed that he had wonderfully recovered the high spirits of youth, and even a remarkable portion of physical strength. His latest drama, *The Foresters*, now received his attention, and in March 1892 was produced at New York, with Miss Ada Rehan as Maid Marian. During this year Tennyson was steadily engaged on poetical composition, finishing "Akbar's Dream," "Kapiolani," and other contents of the posthumous volume called *The Death of Œnone*, 1892. In the summer he took a voyage to the Channel Islands and Devonshire; and even this was not his latest excursion from home, for in July 1892 he went up for a visit to London. Soon after entering his eighty-fourth year, however, symptoms of weakness set in, and early in September his condition began to give alarm. He retained his intellectual lucidity and an absolute command of his faculties to the last, reading Shakespeare with obvious appreciation until within a few hours of his death. With the splendour of the full moon falling upon him, his hand clasping his Shakespeare, and looking, as we are told, almost unearthly in the majestic beauty of his old age, Tennyson passed away at Aldworth on the night of the 6th October 1892. *Cymbeline*, the play he had been reading on the last afternoon, was laid in his coffin, and on the 12th he was publicly buried with great solemnity in Westminster Abbey. Of the twelve eminent men who supported the coffin, seven had already followed him in 1902—Argyll, Dufferin, Selborne, Jowett, Froude, Lowell, and Paget. Lady Tennyson survived until she reached the age of her husband when he died, and was buried at Freshwater in August 1896.

The physical appearance of Tennyson was very remarkable. Of his figure at the age of thirty-three Carlyle has left a superb portrait: "One of the finest-looking men in the world. A great shock of rough, dusky, dark hair; bright, laughing, hazel eyes; massive aquiline face, most massive yet most delicate; of sallow brown complexion, almost Indian-looking, clothes cynically loose, free-and-easy, smokes infinite tobacco. His voice is musical, metallic, fit for loud laughter and piercing wail, and all that may lie between; speech and speculation free and plenteous; I do not meet in these late decades such company over a pipe." He was unusually tall, and possessed in advanced years a strange and rather terrifying air of sombre majesty. But he was, in fact, of a great simplicity in temperament, affectionate, shy, still exquisitely sensitive in extreme old age to the influences of beauty, melancholy, and sweetness. Although exceedingly near-sighted, Tennyson was a very close observer of nature, and at the age of eighty his dark and glowing eyes, which were still strong, continued to permit him to enjoy the delicate features of country life around him, both at Aldworth and in the Isle of Wight. His *Life* was published, with admirable piety and taste, in two volumes, by his son, Hallam, second Lord Tennyson, in 1897.

At the time of his death, and for some time after it, the enthusiastic recognition of the genius of Tennyson took popular forms which were excessive and which it was obvious could not be enduring. We are now feeling the reaction against this extravagance, and criticism has of late been little occupied with the poet. The reason of this is easy to find. For an unusually long period this particular poetry had occupied public and professional opinion, and all the commonplace things about it had been said and re-said to satiety. It lacks for the moment the interest of freshness; it is like a wonderful picture seen so constantly that it fails any longer to concentrate attention. For a final estimate of Tennyson we must wait until a generation arises which is not under the spell of the overwhelming personal prestige which his sixty years of unceasing production gave him among his younger contemporaries. No poet has ever held England, no poet but Victor Hugo has probably ever held any country, quite so long under his unbroken sway as Tennyson did. As he recedes from us, however, we begin to see that he has much closer a relation to the great Georgian writers than we used to be willing to admit. The distance between the generation of Wordsworth and Coleridge and that of Byron and Shelley is not less—it is even probably greater—than that which divides Keats from Tennyson, and he is more the last of that great school than the first of any new one. The qualities in which he seems to surpass his immediate predecessors are exactly those which should be the gift of one who sums up the labours of a mighty line of artists. He is remarkable among them for the breadth, the richness, the substantial accomplishment of his touch; he has something of all these his elders, and goes farther along the road of technical perfection than any of them. We still look to the earlier masters for supreme excellence in particular directions: to Wordsworth for sublime philosophy, to

Coleridge for ethereal magic, to Byron for passion, to Shelley for lyric intensity, to Keats for richness. Tennyson does not excel each of these in his own special field, but he is often nearer to the particular man in his particular mastery than any one else can be said to be, and he has in addition his own field of supremacy. What this is cannot easily be defined; it consists, perhaps, in the beauty of the atmosphere which Tennyson contrives to cast around his work, moulding it in the blue mystery of twilight, in the opaline haze of sunset: this atmosphere, suffused over his poetry with inestimable skill and with a tact very rarely at fault, produces an almost unfailing illusion or mirage of loveliness, so that, even where (as must sometimes be the case with every poet) the thought and the imagery have little value in themselves, the fictive aura of beauty broods over the otherwise undistinguished verse. Hence, among all the English poets, it is Tennyson who presents the least percentage of entirely unattractive poetry. In his luminous subtlety and his broad undulating sweetness, his relationship with Virgil has long been manifest; he was himself aware of it. But he was also conscious that his exquisite devotion to mere lucidity and beauty might be a snare to him, and a happy instinct was always driving him to a study of mankind as well as of inanimate nature. Few English writers have known so adroitly as Tennyson how to bend the study of Shakespeare to the enrichment of their personal style. It should be added that he was a very deep and original student of literature of every description, and that the comparatively few specimens which have been preserved of his conversation contain some of the finest fragments of modern appreciation of the great poets which we possess. This is worthy of consideration in any attempt made to sketch the mind of a man who was above all other masters of recent literature an artist, and who must be studied in the vast and orbic fulness of his accomplishment in order to be appreciated at all. (E. G.)

Tenterden, a municipal borough and market town of Kent, England, in the Ashford parliamentary division of the county, 18 miles south-east of Maidstone, on the South-Eastern and Chatham Railway. The town received incorporation charters from Henry VI. and Elizabeth. The church (Perpendicular), with its famous steeple, is well known for the legend connecting it with Goodwin Sands. The story is that the Abbot of St Augustine, Canterbury, diverted the funds by which the sea-wall protecting Earl Godwin's island Lomsa was kept up, for the purpose of building Tenterden steeple, the consequence being that in 1099 an inundation took place and "Tenterden steeple was the cause of the Goodwin Sands." Population (1881), 3620; (1901), 3243.

Tepic, a territory of the Mexican Republic, bounded on the N. by the states of Sinaloa and Durango, on the S. by Jalisco, on the E. by Zacatecas and Jalisco, and on the W. by the Pacific. Area, 11,279 square miles. Population (1895), 148,776; (1900), 149,677. The territory is divided politically into six *partidos*. The value of the agricultural products in 1896 was $6,990,622. The mining interests are also important. The capital, TEPIC, has a population of 14,560, fine public buildings, and considerable manufacturing interests, which would be largely increased with better transportation facilities, but there are no railways in the territory. San Blas, is the principal port, and does a large business with the entire Pacific coast. It is connected with Tepic by a fairly good waggon road.

Teplitz, or TÖPLITZ (Czech, *Teplice*, which signifies "warm bath"), a town and watering-place in Bohemia, 47 miles north-west of Prague. Population (1890), 20,262; (1900), 24,110, mostly German and Catholic. In 1895 the village of Schönau was incorporated with the town, which now bears the official name of Teplitz-Schönau. In addition to its textile, chemical, and hardware industries, Teplitz now manufactures machinery and metal goods, glass, imitation jewellery, hosiery and knitted goods, stoneware, and sugar, besides carrying on dyeing and calico-printing. The patients now number nearly 6000, and the passing visitors over 23,000.

Terek (Russian, *Terskaya Oblast*), a province of north Caucasia, Russia, bordering on the Caspian Sea. It has an area of 23,548 square miles, and its population, which was 615,660 in 1884, numbered 933,485 (domiciled only) in 1897, when the female population numbered 445,996, and the urban population 115,179. According to Dr Pantukhoff's researches, malaria is prevalent everywhere except at the foot of the mountains, and is especially deadly along the Caspian shore. Notwithstanding this, however, there has been a steady flow of Russian immigration into the province, the Russian population now forming considerably more than a third of the whole; in 1895 there were 312,443 Russians out of a total population of 871,148. In the same year the numbers of the inhabitants of other nationality were (approximately): Ossets, 90,000; Kabardians, 80,000; eastern mountaineers (Tchetchens, Ingushes), 316,500; Kumyk Tatars, 31,500; Armenians, 13,700; the remainder being—Georgians (4500), Germans (8440), and Persians (2400). The province is divided into seven districts, the chief towns of which are Vladikavkaz (43,843), which is also the capital of the province, Groznyi (15,599), Kizlyar (7324), Nalchik (2571), Pyatigorsk (18,638), Sunzhinsk and Khasavyurt, the two last being mere nomad centres of administration. Other towns are Georgievsk (11,532) and Mozdok (14,583). Agriculture has developed greatly on the prairies, and in 1900 the total area under cereal crops was 1,336,900 acres, while the average yield in 1895–99 was: Rye, 786,000 cwt.; wheat, 1,525,000 cwt.; oats, 256,000 cwt.; and barley, 411,000 cwt.—all cereals, 8,273,000 cwt.; also potatoes, 1,172,000 cwt. The vine is very extensively cultivated, especially in the districts of Kizlyar and Pyatigorsk, where no less than 1,500,000 gallons of wine are made annually. Improved agricultural machinery is coming more and more into general use. Cattle-breeding is widely engaged in, and fishing is a valuable source of income, especially at the mouth of the Terek, where nearly 2000 tons of fish are obtained and 2770 cwt. of caviare made every year. Bees are generally kept, there being in the province over 200,000 hives, which yield every year about 4,000,000 roubles worth of honey and wax. Melons, cucumbers, sunflowers, &c., are extensively grown. Manufacturing industry is still in its infancy, and in 1898 the aggregate returns of all factories only amounted to a little over 4,000,000 roubles. Mining is also insignificant in character, only 106 ℔ of silver (Sadonsk) and 1890 cwt. of lead being produced in 1889. Naphtha, however, is obtained in large and growing quantities (390,500 tons in 1899) at Groznyi. Some salt is also obtained. The railway, which formerly stopped at Vladikavkaz, on the northern slope of the Caucasus, has now been continued from the Beslan station, near Vladikavkaz, to Petrovsk on the Caspian Sea, and thence to Baku, where it joins the trans-Caucasian line from Batum to Baku. There were in 1898, 15 middle schools for boys and girls, and 389 primary schools (15,445 boys and 5118 girls). No less than 115 had school gardens, while sericulture was taught in 40 primary schools and bee-keeping in 16.

Tergovista, the chief town of the district of Dămbovitza, Rumania, picturesquely situated at the foot of the Carpathians, on the right bank of the Jalomitza, 48 miles N.N.W. of Bucharest. Population (1900), 9398. Formerly it was the capital of Wallachia, and in the 16th century had a population of 60,000, and contained 70 churches and 40 convents within its strongly fortified enceinte. In 1515 Neagru Bassaraba, the founder of the cathedral of Curtea d'Argesh, constructed the metropolitan church at Tergovista, one of the finest in the country, which with several others is still existent.

Tergu Jiu, chief town of the district of Gorj, Rumania, 60 miles N.N.W. of Craiova and near the Transylvanian Alps. It is the seat of a court of first instance, and has five churches. The annual fair is held on 15th August. Anthracite coal is found in the neighbourhood. Population (1895), 5400; (1900), 6634.

Terim. See ARABIA.

Termini, a seaport town of the province of Palermo, Sicily, Italy, on the north coast, 23 miles east-south-east of Palermo by rail. It has an archæological collection, a picture gallery, a technical school, and a navigation school, and produces macaroni (a speciality), olive oil, wine, liquorice, sulphur, and lime. It has also tunny-fishing, and trade in sulphur, fish, fruits, &c. The harbour is 12 to 25 feet deep. In 1897 it was cleared by 276 vessels of 82,398 tons. There is a hydropathic attached to the baths. Population (1881), 22,861; (1899), about 32,000.

Termites are insects with four wings which are developed outside the body (a large proportion of the individuals become adult, however, without wings appearing at all). The wings are of nearly one size, of long, narrow form, of paper-like consistence, and in repose are placed flat on the back of the insect so that only one wing shows. After a short time the wings are shed, and only small stumps remain as evidence of the individual being a winged form. The mouth has strong mandibles. Formerly Termites were classed as a part of the Order Neuroptera, but more recently they have been separated by certain zoologists from the true Neuroptera, and associated with some other forms as an Order Corrodentia. By Packard they have been associated with Mallophaga, and called Platyptera. They are, however, really an isolated form as much allied to Orthoptera as to Neuroptera, and now constitute by themselves the Order Isoptera, of which about 300 species are known. There is no great structural diversity in the Order, all the species being referred to the single family Termitidæ, which is therefore synonymous with the Order Isoptera. Termites are more widely known as White Ants, but as they are extremely different from true ants, and as they are rarely white, this designation is very deceptive, and should be abandoned.

Termites are found only in warm climates, where they are sometimes very destructive. They are vegetarian, but occasionally eat, or destroy, dry animal matter. The basis of their alimentary regimen is woody matter. Some of them make use of fungi growing in their abodes as food; some cut and store grass; others prepare a peculiar kind of food, which is stored in a tough, dry form, so that it has to be moistened before it can be eaten. Termites are social insects; many of them construct large edifices called termitaria and often spoken of as nests. A termitarium frequently contains an enormous number of individuals forming the society or colony. Termites are totally different in structure and development from all other social insects, but their social existence exhibits numerous analogies with that of the ants and other social Hymenoptera. The most remarkable of these analogies is that the reproduction of the species in each community is confined to a single pair, or to a very limited number of individuals. The members of one society or colony, however numerous or dissimilar they may be, are the descendants of a single pair. The colony is—so far as is known, and on this, as well as on many other points, authentic information is scanty—first started by a pair of winged individuals that cast their wings, secrete themselves in a suitable place, and produce young; the colony, however huge, being subsequently developed by the extreme fertility of the reproductive pair. Very little is known as to how long a colony endures, and, as there is great variety in the social conditions of different kinds of Termites, it is probable that there is considerable difference as to the point in question. As a rule a family or colony has only a single termitarium, but there are cases in which a single family has several separate abodes, though usually only one of them is a real home containing reproductive individuals. The social life in Termites, as well as in all other social insects, is clearly a development of the family life. It is accompanied by extraordinary modifications of the forms of the individuals constituting the society, and by a great division of labour. As regards the forms, or castes, Termites differ totally from other social insects; in the latter case there are great differences between the males and females, and the whole of the castes are of the female sex, whereas in Termites the males and

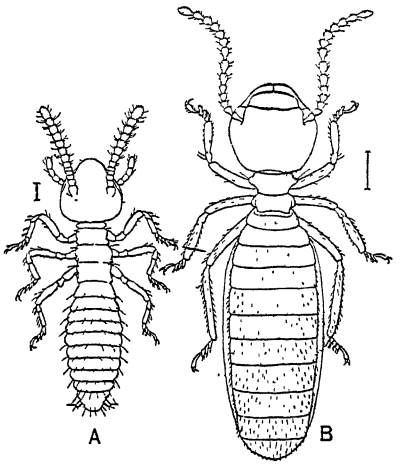


FIG. 1.—A, newly hatched termite; B, worker termite; *Termes nemorosus*.

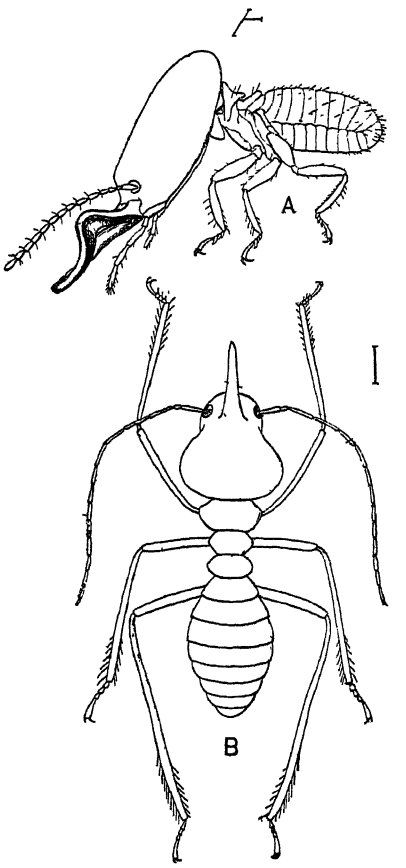

FIG. 2.—A, mandibulate soldier of *Termes nemorosus*; B, nasute soldier of *T. hospitalis*.

females are extremely similar, and the castes are in no way correlative with sex. As the Termite life is a family life, and as there is normally only a single pair of reproductive individuals in each community, it is easily comprehensible that if anything goes wrong with this pair, the community is at once thrown into a state of complete disorganization. But this misfortune is mitigated by a method which Termites have of keeping individuals in an undifferentiated state, and of turning some of them speedily into reproductive individuals, whereby the community is restored to something like a natural condition of activity and growth.

Apart from the forms that are merely juvenile, the following kinds of adults are normally present in a colony: (1) workers, (2) soldiers, (3) winged individuals ready to leave the nest, (4) king and queen.

(1) The *worker* Termite resembles the young in general appearance, and, like the young, has no trace of wings (Fig. 1). The two segments behind the head are more contracted, so that head, thorax, and abdomen are more differentiated than they are in the young. The colour too is different, the young being milky-white, whereas the adult worker is variously pigmented according to its species, but is never milky-white. The worker is generally blind, and in only a few species does it possess rudimentary eyes. The species of the group Calotermitides have no workers. In the other species the workers look after the eggs and young, and perform most, if not all, the industrial work of the community. They are also, in some cases, effective combatants, though quite destitute of any special structures to suit them for this purpose. The sexual organs do not undergo development, but it has been satisfactorily ascertained that both sexes are represented amongst the workers. In certain species the workers seem to be dimorphic, so far as size is concerned, but this point has apparently been only very inadequately considered. Workers form a very large but variable proportion of the members of a community.

(2) The *soldier* Termite is the most extraordinary feature of Termitid biology. It is more varied than any of the other castes, so that most of the species of Termites can be best distinguished by their soldiers. The chief feature of the soldier is an extraordinary development of the head, or of the head and mandibles. There are two very distinct kinds of soldiers: (*a*) the flat-headed or mandibulate soldier, and (*b*) the nasute or rostrate soldier (Fig. 2). In the first kind the head is usually developed out of all proportion to the rest of the body; the mandibles are frequently enormous, and, being in many cases asymmetric, give the appearance of deformity. In the nasute soldier the head is thick or convex, and may be described as unicorn—that is to say, it is prolonged in the middle so as to form a single pointed horn; the mandibles are never largely developed. No species of Termite has both mandibulate and nasute soldiers, although the reverse is sometimes still stated in books. The soldiers of some species are, however, dimorphic to the extent that larger and smaller forms occur in the same nest without intermediates. In other cases soldiers of simply variable size exist. The soldier is blind and wingless, though in a few soldiers minute wing-rudiments can be detected. As in the worker, the development of the sex organs is arrested, but both sexes are represented. The function of the soldiers is probably, as stated by Haviland, defence. The mandibulate soldiers use their heads as blocks to stop gaps in the nests, and employ terrifying but somewhat theatrical devices, making threatening motions and producing noises by movements of the head and thorax. The nasute soldiers emit a fluid from the tip of the rostrum, and dab it upon their enemies with some skill. Soldiers are present in all species of Termites except the South American genus Anoplotermes. It is a remarkable fact that in the group Calotermitides soldiers exist although there are no workers, but in this case the function of the soldier seems to be very much that of a worker. Grassi says that in *Calotermes flavicollis* all the individuals of a community work for the common welfare. Moreover, in the Calotermitides no very great development of the heads or mandibles occurs.

(3) *Adult or Winged Termite.*—Such of the young as do not become workers or soldiers grow and develop after the fashion usual in exopterygote insects. Moults take place, the wing-pads gradually increase in size, eyes appear, and finally pigmentation takes place, and the winged insect is perfected at the last moult (Fig. 3). In prosperous colonies these winged insects are produced in large numbers and emerge at intervals as swarms. They have extremely feeble powers of flight, and apparently scarcely any other capability. They are a favourite food of a large number of animals, including even man. They have well-developed eyes and ocelli, and differ from all the other forms by their greater pigmentation. The function of these adults is to diffuse the species, and to favour crossing outside the family circle. Attainment of this second end is, in some cases, favoured by the fact that the whole of the individuals constituting a swarm consist of one sex only. This extraordinary fact is attested by Grassi, but has not yet received the attention it merits. If a Termite colony be compared with a tree or plant, the winged forms, it is clear, functionally correspond to the flowers and seeds of the tree; indeed, Fritz Muller and Grassi go further,

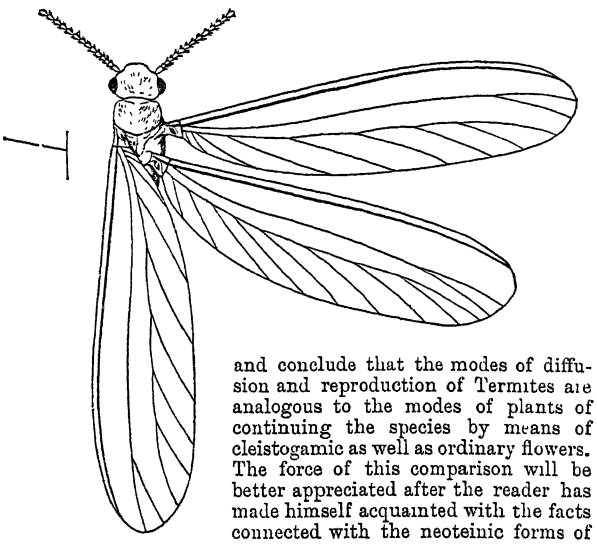

FIG. 3.—Adult Winged Termite: *T. nemorosus;* wings of the right-hand side expanded.

and conclude that the modes of diffusion and reproduction of Termites are analogous to the modes of plants of continuing the species by means of cleistogamic as well as ordinary flowers. The force of this comparison will be better appreciated after the reader has made himself acquainted with the facts connected with the neoteinic forms of Termites.

(4) *King and Queen.*—As a rule each community includes only a single pair of individuals apt for reproduction; these are the royal pair, or king and queen (Fig. 4). They are adult Termites that have shed the wings they formerly possessed. The queen usually undergoes an extraordinary increase in the size of the abdomen, which may be distended to many hundred times its original capacity (Fig. 4, A). In many species the king and queen are confined in a royal cell, out of which they cannot move, though the workers, owing to their smaller size, can get in and out to tend them. In other cases the queen only is so imprisoned, the king being able to leave the cell. In still other cases neither king nor queen is effectually imprisoned. Much discrepancy of opinion exists as to the invariable presence of a king in each nest; this, however, is explained by Haviland's observation that the king is active and timid, and when a nest is opened seeks safety by running away and concealing himself, so that he is sometimes only discovered when the very last fragment of the nest is brought under scrutiny. Another point on which extremely diverse opinions are expressed is the copula of the sexes. It is usually stated that the swarming of Termites is analogous to that of bees and ants, in which groups of insects the conjunction of the sexes takes place at this period, and at this period only. In the Termites the reverse is the case. The swarming is not at all a nuptial flight; indeed, at that time the sexes are not apt for reproduction. Copulation only takes place after a pair have cast their wings and have established themselves together. It is repeated at intervals, and is thus quite dissimilar from the corresponding phenomenon in Hymenoptera. The male has no intromittent organs, so that.

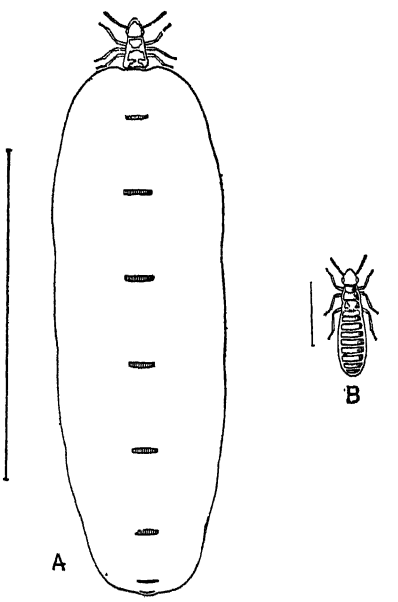

FIG. 4.—A, queen; B, king: *T. nemorosus.*

copula during flight is impossible. Grassi has actually witnessed the act in subsequent life. Haviland is of opinion that in some cases the male fertilizes the eggs without connexion with the female.

(5) *Neoteinic and Substitution Forms.*—When a colony of Termites is deprived of king and queen it can replace them by forms specially prepared. These substitution forms are of two kinds—(*a*) normal adult individuals, and (*b*) neoteinic forms. The latter may be described as unnatural kings and queens possessing reproductive powers, though the wings have never been developed and some other parts of the body have not taken on the fully adult state. Haviland removed the royal pairs from nests of *Termes malayanus*, and after three or four months again examined the nests: in three out of the five cases substitution pairs exactly resembling the original ones, with well-formed wing-stumps, were present; in the other two cases he failed to find the royal cell, and believes that the loss had not been repaired. In other species the bereavement is made good by means of neoteinic instead of normal individuals, and in certain species neoteinic forms are abundantly found. In the case of substitution forms there is usually more than one pair present in a colony, and sometimes numerous pairs exist. Grassi says that in Sicily the colonies of *Termes lucifugus* are kept up entirely by neoteinic kings and queens; in other words, the swarms are nearly or quite useless. The neoteinic forms are compared to cleistogamous flowers; and this curious case is parallel with that of a species of plant whose reproduction should be accomplished entirely by its cleistogamous flowers, though at the same time it produced perfect flowers in abundance. The condition recorded by Grassi is probably extremely exceptional. Fritz Müller found once a colony in which a true king was acting as consort to a considerable number of neoteinic queens, no true queen being present.

In order to understand the curious phenomena presented by the castes and variety of forms of a single species of Termite, it is necessary to become acquainted with their food-habits, which are very peculiar and may be described as communistic. Termites have the habit of eating their cast skins and even their dead companions, and in fact their system of keeping the nest clean seems to be that of eating the refuse of their own bodies till it no longer contains any digestible matter. This cannibalism is the more remarkable, as they will not eat other Termites. The most curious part of their dietary is their complex system of feeding from the matters contained in the alimentary systems of their fellows. When a Termite wishes food it strokes the body of another individual with its antennæ, and the specimen thus caressed exudes from the posterior or from the anterior part of the body a drop of matter, which is eaten by the hungry one. The matter exuded from the posterior part of the body appears to be very different from that yielded by the mouth, so that there are at least two kinds of this excretory food. The proctodæal food (that which comes from the posterior part of the body) is in great favour with adult Termites, but so far as is known it is not used for feeding the newly born young, which are believed to be fed on matter elaborated in the bodies of the adult workers and communicated by their mouths. Subsequently the young take also proctodæal food, and triturated vegetable matter.

Origin of the Castes.—When Termites are hatched from the eggs none of the remarkable differences that are manifested in the individuals in subsequent life can be detected. The sexes are in Termites extremely similar in external characters. When the young are hatched they all appear nearly exactly alike, though on careful examination the sexes can be distinguished. But no other difference than that of sex can be detected. In the article on ANT in vol. ii. of the *Encyclopædia Britannica* it was stated (p. 99) that "the distinction between soldier and worker can be easily seen in the egg." This is contradicted by all modern observations, and is certainly erroneous. It is true that considerable difference of opinion exists as to when the distinction between soldier and worker first becomes evident, but all are agreed that it is not till after the growth is to some extent accomplished. The discrepancy that exists in opinions on this point is due to the facts: (1) that different species have been under observation; and (2) that the modification of the larva to form a soldier may commence at more than one period of the development even in the same species. It being ascertained that all Termites commence as undifferentiated larvæ, the question arises as to what causes the differentiation into castes. This question is the more important as two of the castes (the worker and soldier) do not at all resemble their parents. Grassi, from an examination of the individuals of a large number of nests of *Termes lucifugus*, arrived at the conclusion that all start as undifferentiated larvæ, and that the regular development of Termes up to the perfect insect may undergo a deviation at various periods of life leading to the formation of workers, of neoteinic forms, or of soldiers, the last passing through the stadium of the young worker. He attributes this deviation, which may take place at various periods, to the influence of food, and attaches special importance to the salivary food. The soldiers have no wings; nevertheless a larva, or young nymph that has the rudiments of wings, can be made into a soldier. Grassi has found juvenile specimens that have already assumed the soldier form, although they possess the rudiments of wings. It appears from his observations that the worker may be considered as a form with arrested development, and the soldier as a form with arrested and much diverted development, while the neoteinic forms are individuals in which the reproductive organs are perfectly developed, while some of the bodily structures have suffered arrest of development and even some amount of atrophy.

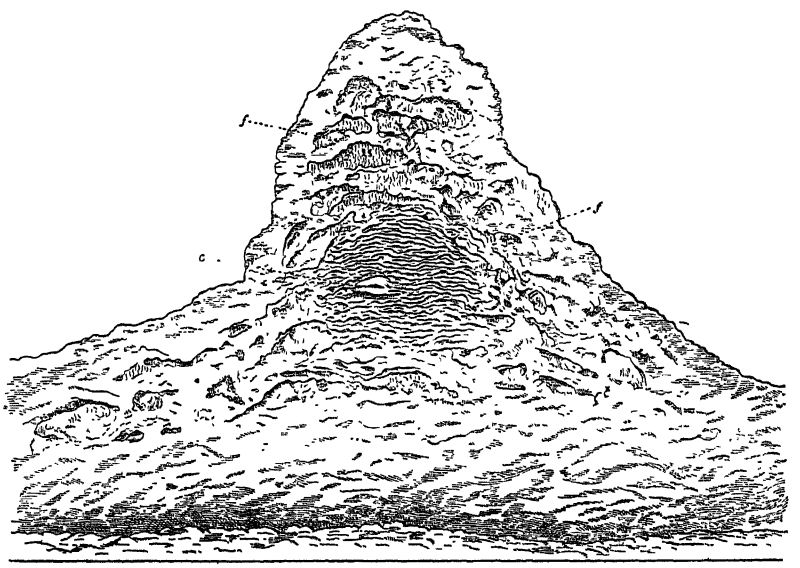

FIG. 5.—Termitarium of *Termes malayanus*: *f*, fungus-chamber; *c*, royal cell.

The soldier form of Termite presents most difficult questions to the biologist, its special structures bearing no approximation to any characters possessed by the parents. Various theories have been proposed to account for this fact, but they are mere guesses. We may, however, mention that it is possible that soldiers and workers occasionally produce young. This has never been actually observed, but specimens have been found with the sexual organs partially developed, and Silvestri has recorded the occurrence of workers with some of the characters of the females, in South America, in a nest of *Termes strunchii*.

Termitaria.—There is nothing in which Termites display more variety than in their dwellings. These are sometimes not constructions at all. The primitive *Calotermes flavicollis*—in which there is no worker—frequently

inhabits rotten places in trees; at most it increases these a little by excavation, and modifies the passages by slight and imperfect barricades. In the case of this species the community never attains a greater number than one thousand individuals, and even this is comparatively rare. On the other hand we have the huge solid structures, 10 or 12 feet high, delineated by Smeathman with cattle standing on their summits. Saville Kent has observed termitaria in Australia 18 feet high. As a rule large termitaria do not occur in considerable numbers in a restricted area, but there are exceptions even to this. At Somerset, Cape York, there is one of the most remarkable Termite cities of the world. Viewed from the sea, it appears as if the plain for a mile or more in extent were covered with pointed pillars varying, according to different accounts, from 6 to 13 feet in height, broad at the base and tapering to the summit, forming regular symmetrical pyramids. In this part of Australia there is also found the "compass," "magnetic," or "meridian" Termite, the mounds of which have somewhat the shape of a tombstone, and have always the same orientation, the wider face of the structure always extending north to south. It has been suggested that this is connected with the necessity of regulating the temperature or the amount of desiccation of the nest, but there is no evidence whatever on the point. A termitarium on being opened displays a vast number of irregular chambers separated by thin partitions (Fig. 5, *f*), the royal cell being placed in the middle (Fig. 5, *c*). The material used is of an earthy nature, but the interiors of many earthy termitaria are largely composed of woody fibre, the refuse proceeding from the alimentary canals of the insects being used for this purpose. A considerable number of the larger Termites use fungi for their food-stuff. There are special chambers where these are cultivated, the matter on which the fungus is grown being of a woody nature and sponge-like in its structure. The fungi make their appearance as small globules. Probably the spores or mycelium are placed in the mass when it is formed by the Termites; but very little is yet known as to this fungus and its mode of treatment by them.

Ternate, one of the two Dutch residencies in the East Indian Archipelago, exercising authority over the area of the ancient kingdoms of Ternate and Tidor (see AMBOYNA and MOLUCCAS). The residency consists of the following groups of islands: the Gilolo or Halmaheira group, the Bachian and the Obi group, the Sula islands, the islands near the western half of New Guinea (Gebeh, Vaigeu, Saluwatti, Misol), the western half of New Guinea as far as 141° E., with the islands in Geelvink Gulf on the north coast of New Guinea, along with others on the south coast. To this residency also belong the state of Banggaai and the Banggaai group in East Celebes. The residency stretches from 2° 43′ to 8° 45′ S., and 121° to 141° E., with an area of 155,800 square miles. The Dutch Government exercises direct authority only over parts of Ternate, Halmaheira, Bachian, and Obi islands. Its rule over the other groups it carries on through the sultans of Ternate and Tidor. The island of Ternate, near the west coast of Gilolo, its volcano, products, &c., were fully described by the Resident De Clercq, who visited the different groups of the residency, more especially the western half of New Guinea. Both the island and town of Ternate suffer from their isolation, and have never regained the importance they had in former centuries. Ternate is a little town, and, in spite of its good harbour, carries on no considerable trade or shipping, numbering only 3000 inhabitants. The density of population throughout the whole residency is calculated at from 0·5 to 1 per square kilometre.

Recent History.—The breaking up of the old Government of the Moluccas has not only not injured Ternate, it has tended to make it perhaps the most important Dutch-Indian political centre of the archipelago east of Celebes. Nominally the sultan is still ruler, but virtually his powers were greatly curtailed by his conventions with the Dutch-Indian Government, under which he surrendered, with the concurrence of his grandees, many of his former rights to the Dutch Resident, who has become the *de facto* governor of the easternmost colonial possessions of Holland, especially since the transfer of Dutch New Guinea in 1901. To the same residency also belongs Tidor, which, however, still has its own sultan, whose dominion likewise extends to other islands, Bachian, Buru, &c. Among the rights surrendered by the sultan of Ternate to the Dutch were those of granting monopolies and mining concessions, now vested in the Dutch Resident. The island of Bachian is being worked by a kind of chartered company. For surrendered rights and privileges the sultan and his grandees received monetary compensations in the shape of annual subventions, and these are also being paid for the losses formerly incurred by the wilful destruction of the nutmeg plantations. The restrictions in the growing of nutmegs have long since been removed, and many nutmeg plantations, with free labour, have been started in Ternate since 1885. In fact, experts now believe that Ternate, and not Banda, was originally the centre of nutmeg-growing. It is a curious fact that Christianity has declined in Ternate latterly, though formerly it was an early stronghold and the number of Europeans settled there has materially increased. (M. K.; H. TI.)

Terni, a town and episcopal see of Perugia, Umbria, Italy, amongst the Apennines, 70 miles north by east of Rome by rail. It has important iron and steel works and iron foundries, at which armour-plates, guns, and projectiles are made for the Italian navy, also steel castings, machinery, and rails, a royal arms factory, and lignite mining. There is a school of industry. Population (1900), 11,000.

Terracina, a town and episcopal see of the province of Rome, Italy, on the Mediterranean coast, 18 miles west-north-west of Gaeta. Excavations made in 1894 on the site of the reputed palace of Theodoric prove it to have been a magnificent temple of Venus, 111½ feet long by 65½ feet wide. Population (1900), 6500.

Terre Haute, a city of Indiana, U.S.A., capital of Vigo county, on the Wabash river, in the western part of the state. It is regularly laid out, divided into ten wards, has a good water-supply, is sewered, and well paved with bricks and granite blocks. Five lines of railway meet here—the Chicago and Eastern Illinois; the Cleveland, Cincinnati, Chicago, and St Louis; the Evansville and Indianapolis; the Evansville and Terre Haute; and the Vandalia. It is in a coal and natural gas region. In 1900 it contained 429 manufacturing establishments, with a total capital of $8,938,107. They employed 5427 hands, and the product had a value of $27,784,619. The leading articles of manufacture were distilled liquors with a value of $16,041,747, flour with a value of $1,363,338, and clothing with a value of $826,000. In 1900 the assessed valuation of real and personal property was $20,414,090, the net debt was $392,455, and the tax-rate was $25·20 per $1000. Terre Haute contains a number of educational institutions, among them the Rose Polytechnic Institute, a technical school opened in 1883. In 1899 the faculty numbered 20, and the attendance was 103. Population (1890), 30,217; (1900), 36,673, of whom 2952 were foreign-born and 1520 negroes.

Terrell, a city of Kaufman county, Texas, U.S.A., on the Texas Pacific and the Texas Midland railways, in the north-eastern part of the state, in the cotton and timber region. Population (1890), 2988; (1900), 6330, of whom 211 were foreign-born and 1517 negroes.

Terriss, William [William Charles James Lewin] (1847–1897), English actor, was born in London, 20th February 1847. After trying the merchant service, medicine, sheep-farming in the Falkland Isles, and tea-planting in Bengal, in 1867 he definitely took to the professional stage, for which his handsome presence, fine voice, and gallant bearing eminently fitted him. He quickly came into favour in "hero" parts, and appeared at the principal London theatres from 1868 onwards. In 1880 he joined Irving's company at the Lyceum, playing such parts as Cassio and Mercutio, and in 1885 he acted there with Mary Anderson, as Romeo to her Juliet, &c. He was then engaged to take the leading parts in Adelphi melodrama, and it was in this capacity that for the rest of his career he was best known, though he occasionally acted elsewhere, notably with Irving at the Lyceum in *Ravenswood*, *Henry VIII.*, *Faust*, and *Becket*. No more popular stage hero ever trod the boards, and his robust method was particularly effective in naval or military parts. On 16th December 1897, as he was entering the Adelphi Theatre, he was stabbed to death by a madman, Richard Archer Prince.

Terry, Ellen Alicia (1848– ——), English actress, was born at Coventry, 27th February 1848. Her parents were both in the theatrical profession, as also have been her sisters Kate, Marion, and Florence, and her brother Fred. Ellen Terry's first appearance was made at the age of eight, under the Keans' management, as the child Mamilius in *The Winter's Tale*, at the Princess's Theatre, London. This was followed by her appearance as Puck at the same theatre. Two years later she played the part of Prince Arthur in *King John* with such artless grace as to win high praise. From 1860 to 1863 and again from 1867 to 1868 she acted with various "stock companies," amassing valuable experience. During this period she acted, in 1867, for the first time with Henry Irving, playing Katherine to his Petruchio in *The Taming of the Shrew* at the Queen's Theatre. When quite a girl she married G. F. Watts the painter, but the marriage was dissolved at an early date. Between 1868 and 1874 she was again absent from the stage (having married Mr E. A. Wardell, an actor whose professional name was Kelly), but she reappeared in leading parts at the Queen's Theatre under Charles Reade's management. In 1875 came an event which set the seal of popular approval on her fame as an actress, in the shape of an engagement to play Portia in an elaborate revival of *The Merchant of Venice* under the Bancrofts' management at the old Prince of Wales's Theatre. Her performance was, indeed, the one bright spot in what proved otherwise an unexpected failure. This was followed by a succession of smaller triumphs at the Court Theatre, culminating in her beautiful impersonation of Olivia (in W. G. Wills's play of that name) in 1878, the result of which was her engagement by Henry Irving as his "leading lady" for the Lyceum Theatre and the beginning of a long artistic partnership. Her Shakespearian impersonations at the Lyceum have been Ophelia in 1878, Portia in 1879, Desdemona in 1881, Juliet and Beatrice in 1882, Viola in 1884, Lady Macbeth in 1888, Katherine (in *Henry VIII.*) and Cordelia in 1892, Imogen in 1896, and Volumnia (in *Coriolanus*) in 1901. Of these Portia and Beatrice were most entirely suited to her method and temperament. Some of Ellen Terry's other most notable performances were as the Queen in Wills's *Charles I.* in 1879, Camma in Tennyson's *The Cup* in 1881, and Margaret in Wills's *Faust* in 1885. With the Lyceum company she several times visited the United States. In 1902, while still acting with Sir Henry Irving, she appeared with Mrs Kendal in Mr Beerbohm Tree's revival of *The Merry Wives of Windsor* at Her Majesty's Theatre.

Teruel, a province of Spain, area 2363 square miles. Population (1887), 241,865; (1897), 247,762. The birth-rate is 3·99 per cent., the proportion of illegitimates being 2·11 per cent.; the death-rate is 3·55 per cent. Education is in a very backward state. The industries are comparatively unimportant. Much land is devoted to pasture that could be cultivated. Extensive forests with fine timber are as neglected as some important coal-beds in the eastern districts. Several hundred thousand acres are devoted to pasture, and forests cover about 600,000 acres.

Teruel, capital of the above province, on the Guadalaviar. Population (1887), 9423; (1897), 9938. Three suburbs have sprung up outside the walls, with broader, well-built streets. Teruel has several good hospitals and asylums for the aged and children, an institute, a normal training school, primary schools, a public library, an athenæum, a meteorological station, a large prison, and eleven churches, besides the handsome cathedral. The town hall is a solid modern building, and the bull-ring is also modern.

Teschen (Czech, *Těšín*; Polish, *Cieszyn*), the chief town of a government district in Austrian Silesia, formerly the capital of the duchy of Teschen, 65 miles south-west of Cracow. Population (1890), 15,220; (1900), 19,142 (estimated at 53 per cent. German, 43 per cent. Polish, and 4 per cent. Czech). It has a museum and four high schools. Its industries have received an important addition in the State printing and lithographic works, and the manufacture of small arms, vehicles, leather, and cloth, together with large saw-mills. There is a considerable trade in spirits, beer, and liqueurs, iron wares, furniture, and timber, cheese, lard, &c.

Testamentum Domini ("Testament of our Lord").—Extracts from the book which bears this title, contained in an 8th-century MS. at Paris, were published by Lagarde in 1856 (*Reliquiae iuris ecclesiastici antiquissimae 80–89*); and a Latin fragment, edited by Dr Montague James, appeared in 1893 (*Texts and Studies*, i. 154). The whole book was first published in Syriac in 1899, with a Latin translation by Mgr Rahmani, the Uniat Syrian Patriarch of Antioch. His text is that of a 17th-century MS. at Mosul, the colophon of which says that the Syriac text was translated from the original Greek "*a Jacobo paupere*," evidently James of Edessa, in A.D. 687; but he makes use of other material, including an Arabic version made from a Coptic copy written in A.D. 927. The Mosul MS. contains the whole Bible in the Peshitto version, followed by the Syrian "Clementine Octateuch," *i.e.*, the collection of ecclesiastical law, in eight books, which was used by the Nestorians and Jacobites. Of this the *Testament* forms the first two books; and according to the title (which, apparently by an error, is made to apply to the whole eight books) it contains the "testament, or words which our Lord spake to His holy Apostles when He rose from the dead." Plainly, it is one of that series of writings, claiming to embody the fundamental rules of the Church, which culminates in the Apostolical Constitutions (*q.v.*).

It falls into three distinct parts: an apocalyptic

introduction (book i. chapters 1–18; the division into books, however, is clearly not original); a "church order" proper (i. 19–ii. 24); and a conclusion (ii. 25–27) of the same apocalyptic character as the introduction. (*a*) The *Introduction* professes to contain the record of the revelation of Himself by the Lord to His Apostles, with whom are Martha, Mary, and Salome, on the evening after His resurrection. He is represented as unfolding to them, at their request, the signs of the end, and giving them instruction on various other topics. Incidentally, the fact becomes plain that this section is composed from the standpoint of Asia Minor and Syria, that it dates from soon after the time of Maximin (235–38) and Decius (249–51), and that it springs from a Christian community of a strictly puritan type. (*b*) The *Church Order* follows the general lines of the Canons of Hippolytus and similar documents. It describes the Church and its buildings (i. 19); the office of the bishop and his functions (i. 19–27); the mystagogic instruction (i. 28) common to this and the Arabic Didascalia, where it occurs in an earlier form, and based in part upon the Gnostic "Acts of Peter"; the presbyter (i. 29–32); the deacon (i. 33–38); confessors (i. 39); the "widows who have precedence in sitting" (i. 40–43), apparently the same persons who are spoken of elsewhere as "presbyteresses" (i. 35, ii. 19); the subdeacon (i. 44) and the reader (i. 45), the order of whose offices seems to have been inverted; virgins of both sexes (i. 46); and those who possess *charismata* or spiritual gifts (i. 47). Next come the regulations for the laity, including the whole course of preparation for and admission to baptism (ii. 1–8), confirmation (ii. 9), and the eucharist (ii. 10); after which there follows a series of miscellaneous regulations for Easter and Pentecost (ii. 11–12), the agape (ii. 13), the funds of the Church (ii. 17–20), the visitation of the sick (ii. 21), the use of psalmody (ii. 22), the burial of the dead (ii. 23), and the hours of prayer (ii. 24). (*c*) The *Conclusion* (ii. 25–27) brings us back to the injunctions of the Lord as to the keeping of these precepts, a special charge to John, Andrew, and Peter, and a statement that copies of the Testament were made by John, Peter, and Matthew, and sent to Jerusalem by the hands of Dosithaeus, Sillas, Magnus, and Aquila.

In all this there is much that is peculiar to or characteristic of the *Testament*. First and foremost is its ascription to the Lord Himself, which we can hardly be mistaken in regarding as an attempt to claim yet higher sanction than was claimed by the various compilations which were styled "apostolic." This fact alone would lead us to infer the pre-existence of certain of the latter. Again, the whole tone of the *Testamentum* is one of highly strung ascetism, and the regulations are such as point by their severity to a small and strictly organized body. They are "the wise," "the perfect," "sons of light"; but this somewhat Gnostic phraseology is not accompanied with any signs of Gnostic doctrine, and the work as a whole is orthodox in tone. They are set in the midst of "wolves," despised and slighted by the careless and worldly: there is frequent mention of "the persecuted," and of the duty of "bearing the cross." There appears to be no *locus poenitentiae* for serious sins excepting in the case of catechumens, and there is a notable "perfectionist" tone in many of the prayers. *Charismata*, and above all exorcisms, occupy a very important place: there is a vivid realization of the ministry of angels, and the angelic hierarchy is very complete. Great stress is laid upon virginity (although there is not a sign of monasticism), upon fasting (especially for the bishop), upon the regular attendance of the whole clerical body and the "more perfect" of the laity at the hours of prayer. The church buildings are very elaborate, and the baptistery is oblong, a form found apparently only here and in the Arabic Didascalia. Amongst the festivals mentioned are the Epiphany, Easter, and Pentecost. With regard to the prayers, they are based upon forms common to this and other Church orders, but have many lengthy interpolations of an inflated and rhapsodic kind. The bishop appears to rank far above the presbyters (more conspicuously so, for example, than in the Canons of Hippolytus), and the presbyters are still divided into two classes, those who are more learned and those who are of mature age. The deacons have functions in the Eucharist and about the altar which point to an early date; they have also much administrative work of an important kind, and especial provisions are made for the care of the sick and the dead, and the burial of those who perish by shipwreck. One of the deacons is to be chosen as "chief deacon" (*protodiaconus* i. 19, *cf.* i. 34), and is charged with the care of pilgrims. There are no doorkeepers or singers, who begin to appear *circ.* A.D. 340. The honour given to confessors is very conspicuous, and points back to an early date. But remarkable above all is the position given to women. We have "widows having precedence" or presbyteresses, three in number, deaconesses, virgins, and widows who are in receipt of the alms of the Church; and the first named occupy a place of very great dignity, which is almost unequalled elsewhere (excepting in the earlier form of the apocryphal and Montanistic *Acts and Martyrdom of Matthew*, where the relation of the πρεσβῦτι and deaconess corresponds with that of the *Testament*), and which was formally condemned by the Council of Laodicea in Phrygia.

What conclusion is to be drawn, then, as to the age and character of the *Testament?* Mgr Rahmani's view, that it is a work of the 2nd century, is universally discredited; nor has Dr Funk's contention found acceptance, that it and the Canons of Hippolytus are alike derived ultimately from the eighth book of the *Apostolic Constitutions*. It is now generally agreed that the Apocalypse at the beginning is pre-Nicene (A.D. 250–325), and that it originates from Asia Minor, probably from Montanistic circles. On its first appearance, however, Dr Harnack contended that this was an independent work, upon which the Church Order had been grafted, and that as a whole it dated from *circ.* A.D. 400. To this it must be replied that the unity of thought and atmosphere is such as to show that the work is one whole (subject no doubt to a certain amount of redaction and interpolation), and that the apocalyptic part was composed as an introduction to the rest. As to the central portion (i. 19–ii. 24) it is a Church Order of the same kind as the Canons of Hippolytus and the Egyptian Church Order, standing nearer to the latter than the former, and especially to the latter in the Latin form published in 1900 by Dr Hauler. The precise relation in which these three stand to one another still remains in a measure doubtful, but it seems probable that they are based upon a lost Church Order, to which the Canons of Hippolytus stands nearest. If this be the case, the *Testamentum* would seem to date from the latter part of the 3rd century, and to emanate from some Montanistic or semi-Montanistic community; and such is Mr Rackham's conclusion. With this agree most of the indications given above, especially that from the position of women in the *Testament;* and there is nothing which points strongly to a later date for the whole work.

On the other hand, it shows signs of later redaction, as was indeed inevitable in the case of a work which has had a living history as part of a codex of Church law. Such signs may be discerned in the interpolations

in the prayers; possibly in the reference to the chief deacon, for elsewhere no single deacon is distinguished *by name* until the close of the 4th century; in the reference to the Epiphany, which is first heard of elsewhere at the beginning of the 4th century. They probably point, as Bishop J. Wordsworth has suggested, to a redaction on a large scale about A.D. 400; but the evidence seems scarcely sufficient to justify the conclusion that this revision was due to the school of Apollinaris of Laodicea (died *circ.* A.D. 390).

Tetschen, the chief town of the government district of the same name in north Bohemia, near the Saxon frontier, 20 miles E.N.E. of Teplitz. It is situated at the confluence of the Polzen with the Elbe, on the right bank of the latter river opposite Bodenbach, with which it is connected by a chain bridge (1855) and two railway bridges. It is the seat of an Austrian custom-house. The handsome château of the Thun family (built in 1667–73), which occupies a rocky height above the town, was at one time fortified, and was a place of some importance during the Seven Years' War. The shipping amounts to an annual total of over 4000 vessels. In addition to being the principal emporium for the Austrian traffic on the Elbe, Tetschen has a considerable industry, its products comprising chemicals, oil, soap, cotton stuffs, plaster of Paris, glazed and coloured paper, cellulose, beer, flour, preserved fish, &c. Population (1890), 7299; (1900), 9692.

Tetuan (*Tettáwan*), the only open port of Morocco on the Mediterranean, a few miles south of the Strait of Gibraltar, and about 40 miles east-south-east of Tangier. It contains many fine residences of Moorish families expelled from Spain. Exports: annual average of the years 1896 to 1900 inclusive, £5746; imports, £36,609. The shipping entered and cleared in 1899 and 1900 averaged 22,900 tons annually. Population about 25,000.

Teutoburger Wald, a mountain range of Germany, stretching north-west to south-east, along the borders of the Prussian provinces of Hanover and Westphalia and the principality of Lippe, for a distance of 70 miles, but with a width of only 1¼ to 3 miles. There is a well-marked main chain, accompanied, especially in the middle, by smaller subsidiary chains. The highest elevation is Völmerstod, 1535 feet, near the east end; but the height diminishes gradually towards the west. The main chain is pierced by several deep gaps or "doors," through some of which important railways have been carried; *e.g.*, the line connecting Paderborn and Hanover, and that connecting Herford and Hamm. The chief geological formations belong to the Cretaceous system, backed towards the north and east by Jurassic and Triassic formations. The entire range is for the most part well wooded. The name is first found in Tacitus, but it is uncertain which mountain range he intended to indicate; consequently it is still a matter of dispute amongst scholars where the famous battle in the Teutoburger Wald was actually fought in which Arminius, in the year A.D. 9, at the head of the Germanic tribes annihilated the legions of Varus. Mommsen considers it to have been fought near the source of the Hunte, north of Osnabruck, and beyond (north of) the range altogether. Nevertheless the Grotenburg (1275 feet), 2½ miles south-west from Detmold, is crowned with a heroic monument to Hermann (Arminius), the Cheruscan chief, erected in 1838–46 and 1875, at a cost of £13,500, the battlefield having been placed by some scholars at the south-west foot of that hill. The work, which was designed by E. von Bandel, consists of a gigantic statue of the chieftain, 56½ feet high, standing on an arched pediment 100 feet high. The materials employed are copper and iron.

Tewfik Mohammed (1852–1892), KHEDIVE OF EGYPT, son of the Khedive Ismail, was born on 15th November 1852. Although the eldest son, he was not sent to Europe to be educated, like his younger brothers, but was left to grow up in his native country. In 1866 Ismail succeeded in his endeavour to alter the order of succession to the Khediviate. The title, instead of passing to the eldest living male descendant of Mehemet Ali, was now to descend from father to son. Ismail sought this alteration mainly because he disliked his uncle, Halim Pasha, who was his heir-presumptive, and he is supposed to have imagined that he would be able to select whichever of his sons he pleased for his successor. But he found, after the change had been made, that the Powers interpreted the new arrangement as applying strictly to the eldest son. Tewfik therefore became heir-apparent. He was given a palace near Cairo to live in, and for twelve years he passed an uneventful life, farming, and establishing a reputation for good sense and fair dealing with his fellah tenants. In 1878 he was appointed President of the Council after the dismissal of Nubar Pasha. He held this office only for a few months; but this was long enough to show that, if he was unambitious and not particularly intelligent or energetic, he had the wisdom to refrain from taking a part in the intrigues which then formed the chief part of political life in Egypt. He went back to his estate, and settled down once more, with the single wife to whom he was devoted, to a quiet country life. He was not left undisturbed for long. On 26th June 1879 Ismail was deposed by the Sultan, who sent orders at the same time that Tewfik should be proclaimed Khedive. The new Viceroy was so little pleased by the news of his accession that he soundly boxed the ears of the servant who first brought it to him. For some months the country passed through troubled times. Tewfik's people were dissatisfied, his army disaffected; his advisers were nearly all of the adventurer class, with their own ends to gain; and he himself had neither the character of a strong ruler nor the experience that would have enabled him to secure an orderly administration of affairs. Disorder prevailed until November 1879, when the Dual Control was re-established by the Governments of Great Britain and France. For nearly three years Major Baring (afterwards Lord Cromer), Mr (afterwards Sir) Auckland Colvin, and M. de Blignières practically governed the country. During all this time the disaffection in the Egyptian army was increasing. Tewfik has been blamed for his failure to take a firm line with the rebels, but his attitude was governed by his relations with Great Britain and France, and it was his endeavour to carry out suggestions which constantly varied that finally led to the outbreak of Arabi Pasha's armed rebellion. In July 1882 the attitude of Arabi, who was carrying out defensive works on a large scale, made it necessary for the British Admiral (Sir Beauchamp Seymour, afterwards Lord Alcester) to

declare that he would bombard the forts of Alexandria unless they were handed over to him. Before the bombardment began it was suggested to Tewfik that he should leave the city and embark either upon a man-of-war belonging to one of the neutral Powers, or in his own yacht, or in a mail steamer which was then in the port. His answer was, "I am still Khedive, and I remain with my people in the hour of their danger." At his palace of Ramleh, 3 miles from the town, he was beyond reach of the shells, but his life was nevertheless imperilled. When the rebel soldiers attacked the palace he managed to make his escape and to reach another palace after passing through the burning streets of Alexandria. Here he was obliged to agree that a guard of British blue-jackets should protect him from further risk. He showed his courage equally during the cholera epidemic at Alexandria in 1883. He had gone back to Cairo after the battle of Tel-el-Kebir, had consented to the reforms insisted upon by Great Britain, and had resumed the functions of a constitutional ruler under the guidance of Lord Dufferin, the British Special Commissioner. When the cholera broke out, he insisted upon going to Alexandria. His wife accompanied him, and he went round the hospitals, setting an excellent example to the authorities of the city, and encouraging the patients by kind and hopeful words. In 1884 Sir Evelyn Baring went back to Egypt as diplomatic agent and consul-general of Great Britain. His first task was to demand that Tewfik should abandon the Sudan. Tewfik gave his consent with natural reluctance, but, having consented, he did everything he could to ensure the success of the policy which Baring had been sent to carry out. He behaved with equal propriety during the negotiations between Sir H. Drummond Wolff and the Turkish envoy, Mukhtar Pasha, in 1886. His position was not a dignified one—that of a titular ruler compelled to stand by while others discussed and managed the affairs of his country. The Sultan was his suzerain; in Great Britain he recognized his protector: to the representative of each he endeavoured to show friendliness and esteem. As time went on his confidence in Baring increased, until at last he deferred to the strong mind of the British agent in almost everything. He had, like most weak men, occasional outbursts of activity, occasional impulses to act upon his own initiative. For instance, he dismissed Nubar Pasha at a moment when Baring was not in Egypt; and Riaz Pasha was also dismissed in his turn without any consultation between the Khedive and the British agent. Baring encouraged him to show his activity in matters of administration, and he took a strong interest in all matters connected with irrigation, education, and justice. He was not a strong man either in mind or in character, but he showed a genuine desire to govern his country for its own benefit. He understood the importance to Egypt of British assistance and support: his natural shrewdness made him accept the British conditions; his natural good feeling kept him from any inclination to intrigue. In private life he was courteous and amiable. He had no desire to keep up the unapproachable state of an Oriental ruler. Indeed, in many ways his manners and habits were less Oriental than European. He died on 7th January 1892, at the Helouan Palace near Cairo, and was succeeded by his eldest son, Abbas Pasha, born in 1874. (H. H. F.)

Texarkana, a city lying in the two states of Texas and Arkansas, the state line passing down the middle of the main street. The portion on either side of the line is, of course, a separate municipal corporation. Texarkana, Arkansas, is the capital of Miller county, and Texarkana, Texas, is in Bowie county. The altitude is 295 feet. It is regularly laid out on a level site, and is an important railway centre, no fewer than six railways intersecting here. It is situated in a timber and cotton region, contains cotton-gins, compresses, and oil-mills, and ships large quantities of cotton. It has lumber-mills and car shops. Population (1880), Texarkana, Ark., 1390; Texarkana, Texas, 1833—total, 3223; (1890), Texarkana, Ark., 3528; Texarkana, Texas, 2852—total, 6380; (1900), Texarkana, Ark., 4914; Texarkana, Texas, 5256—total, 10,170. Of the population of Texarkana, Ark., in 1900, 120 were foreign-born and 2078 negroes; of that of Texarkana, Texas, 192 were foreign-born and 1964 negroes.

Texas, the largest state of the American Union, situated on the south central border. In the closing decades of the 19th century it made great strides in its material welfare. In 1880 the state was still lavishly distributing its public domain to settlers, educational institutions, railways, and as rewards for services. Immigration was invited, and there was little thought of the vast landed legacy being exhausted. There were no railways except in the eastern third, aggregating hardly 500 miles. There were practically no constructed public highways, or laws for making them. Although ordinarily considered a prairie state, Texas possessed the largest area of woodland (64,000 square miles) of any American commonwealth, but the modern lumbering industry was unknown. Mining and manufacturing were undeveloped. The school system was in a primordial condition; there was no county superintendence and no system of instruction, the scholastic year was of only four months' duration, and the attendance limited to pupils between eight and fourteen years of age. The university and other institutions of higher education had not been organized. Since 1880 the population has steadily grown in number and density, although it is still the least densely settled of all the American states east of the Rocky Mountains, with the exception of Florida and the Dakotas, and has not attained one-half the average density (25·6) of population of the entire Union. In 1900 the public domain theoretically had been entirely expended, but in fact fully 40,000,000 acres were still owned by the commonwealth in trust for the public schools, university, and other state institutions. In 1880 the total population was 1,591,749, or 6·1 persons to the square mile; in 1890 it was 2,235,523, or 8·5 to the square mile; in 1900 it was 3,048,710, or 11·6 to the square mile. The increase in population from 1880 to 1890 was 40·4 per cent., and from 1890 to 1900 36·4 per cent. In 1900 there were 46 incorporated cities and towns having more than 2000 and less than 5000 inhabitants; 16 having more than 5000 and less than 10,000; 6 of more than 10,000 and less than 25,000; and 5 with more than 25,000, namely, San Antonio (53,321); Houston (44,633); Dallas (42,638); Galveston (37,789); and Fort Worth (26,688). The urban population (classing as such all persons living in places of more than 4000 inhabitants) was 13 per cent. of the total population in 1890, and 14·9 per cent. in 1900. Of the total population in 1900, 1,578,900 were males and 1,469,810 were females. The foreign-born numbered 179,357 and the negroes 620,722, being respectively 5·9 per cent. and 20·3 per cent. of the total population. The illiterate adult males (unable to write) numbered: native white, 30,017, out of 514,188; foreign-born white, 21,773, out of 85,773; negroes, 61,744, out of 136,875.

Agriculture and Forestry.—Since 1880 the state has become the largest cotton-producing state or country in the world. Texas also ranks first in the Union in the production of cattle and horses. There were in the state, according to the census of 1900, 352,190 farms, with an acreage of 125,807,017, of which 19,576,076 acres were improved, and 106,230,941 unimproved 286,654 farms were

owned by white persons, 65,536 by coloured. The total value of farm property was estimated at $962,476,273, and the value of the farm products at $239,823,244. The lumbering interest has grown to a vast industry, and its product has been distributed by rail over Mexico, the eastern Rocky Mountain states, and by ship to all the West Indian and South American ports. Other forest products of a local character, for which no statistics are obtainable, have also developed enormously. It is estimated that 500,000,000 feet of lumber are produced annually.

Mining and Manufactures.—It was not until 1889 that Texas finally passed a law permitting mineral claims upon the public lands by individuals; hence the development of its mineral resources has been backward. In 1898 the gold product was valued at $300, and the silver at $611,426. Coal mining has steadily increased; 686,734 short tons were produced in 1898, valued at $1,139,763. Lignite, vast beds of which formerly remained unused, is also mined in quantities. Salt, which used to be entirely derived from Europe, is now exported, the yield for 1898 being 254,284 barrels, valued at $119,700. The extensive beds of gypsum in the north-west are being worked; in 1898, 34,215 short tons were produced, valued at $58,130. Rich fields of cinnabar have been opened in Trans-Pecos province; 1000 flasks were produced in the state in 1900, valued at $50,000. Building materials, such as granites, sandstone, limestone, marbles, and cement, are growing in importance. In 1898 101,590,000 bricks were produced, valued at $602,988. Oil fields have been opened; 546,070 barrels of crude petroleum were produced, valued at $277,135, or seven times the amount produced in the previous year. There were 12,289 manufacturing establishments in 1900, an increase of 133·3 per cent. for the decade, with a capital of $90,433,882 and a product valued at $119,414,982.

Education.—Since 1880 the public schools have been organized upon a model system; state, county, and municipal superintendence has been provided; the standard and pay of teachers raised; the public school fund augmented, and vacation normal institutions established. The school age has been extended, and the number of teachers employed greatly increased. The permanent school fund consists of 30,000,000 acres of land, and cash and bonds. The latter in 1894 was $2,162,600; in 1899 it had increased to $6,447,247. The available annual school fund, the revenues from taxes and sale and lease of lands, in 1899 amounted to $3,232,624. In 1895–96 616,568 children were enrolled in the public schools, or 20·7 per cent. of the population. The number of teachers employed was 13,217. Of the children instructed in 1894, 472,963 were white and 157,340 coloured. The State University was not organized until 1884. It is under the control of a board of regents nominated by the governor. The main institution, situated at Austin, is the head of the state public school system, and admits students without entrance examinations from approved state high schools, the state normal school, and the agricultural and mechanical colleges, both sexes being admitted on equal terms. In 1899 there were 150 affiliated schools throughout the state, which, after thorough examination by a committee of the university faculty, sent graduates to the university without entrance examination. The income of the university is derived from bonds, the leases of lands belonging to the university (2,500,000 acres), and annual appropriations from the state. The total expenses for 1899–1900 were $155,366. In addition to the main university at Austin, there is a medical branch at Galveston, which requires a four years' course. The expenses of the medical department for 1899–1900 were $59,919. In 1897–98 the university had a total enrolment of 812 students.

Penal and Charitable Institutions.—The prison system has been placed entirely under state control, and its affairs are conducted upon a more humane and more economic basis. An institution for coloured dependents at Austin, a reformatory for youthful penal offenders at Gatesville, and a new and third insane asylum near San Antonio have been provided. A home for dependent Confederate soldiers has been established at Austin, in which about 100 unfortunates took refuge. By a legislative Act of 1899 a biennial appropriation of $250,000 was made for the relief of other indigent Confederate soldiers, which, distributed among 5000 applicants, gave a relief of $1.66 per month.

Finances and Banks.—The total valuation of the assessed property for 1886 was $630,591,029. In 1891 it was $856,202,283; in 1899 it was $921,927,231. Taxation is limited by the constitution to 35 cents on the $100 *ad valorem*, and the county and city taxes to 25 cents. Notwithstanding the enormous growth of wealth and population, the taxes and cost of administration have not increased. The revenues in 1886 from all sources were $2,916,488, and in 1899, $2,700,000. In 1899 there was a cash balance of $1,092,807 in the treasury above all expenses. In 1894 Texas had a bonded debt of $3,992,030. Of this sum $1,405,610 was held as a fund for its various institutions, only $756,990 being in the hands of individuals. In 1899 the debt was $3,989,445. The contract rate of interest has been reduced from a maximum of 12 to 10 per cent. and the legal rate from 8 to 6 per cent. In 1899 there were 194 national banks, which on 20th September of that year had loans and discounts amounting to $46,024,782.

Railways and Commerce.—The railways have increased in length since 1880 from less than 1000 to nearly 10,000 miles in 1900, a mileage exceeded only by Illinois. In 1880 vast trunk lines were initiated to connect the state with the north and east, and to cross the western half to the Rocky Mountains region and the Pacific Ocean. Eight trunk lines of the first and three of the second character now exist. Meanwhile additional railways were constructed in the eastern half. The total of miles in 1899 was 9702. The average indebtedness per mile was $38,267. The total earnings were $45,334,191; the working expenses were 71·73 per cent., or $32,518,118, and the net earnings 3·48 per cent. The national Government, by the expenditure of $6,000,000 upon a system of jetties in the harbour at Galveston, has increased the depth from 13 to 26 feet. The imports have increased from $1,157,370 in 1885 to $3,000,000 in 1899, and the exports from $12,680,000 in 1885 to $78,480,000 in 1899. Four hundred and sixty-eight steam vessels, with an aggregate of 833,497 tons, cleared from Galveston for foreign ports in the year ending 30th June 1899.

Recent History.—The governor is chosen for two years, and by popular custom is usually elected for two terms. There is practically but one party in Texas—the Democratic—and all questions are in reality determined by the popular primaries and state conventions. With the exhaustion of its public domain, the introduction of steam transportation, and the closer competition resulting from readjusted sound conditions, many large corporations began operations in Texas, for the rights and practices of which as public franchises there existed no adequate legislation. This legislation, and the discussion incident thereto, created a period of violent political antagonism, and resulted in a long struggle carried out upon the political rostrum, in the legislative halls, and in the state and Federal courts. Many laws were enacted, especially those regulating railways, and against alien ownership of lands and trusts. Suits were instituted in the courts to recover property illegally held by corporations, and in some instances millions of dollars reverted to the state treasury. The "Free Grass" movement was organized to express discontent at the introduction of barbed wire fences. The rural and pastoral population had held that all unfenced land was public commons. With the coming of the barbed wire all the previously open lands were rapidly enclosed, and thousands of settlers found themselves without pasturage. This feeling gave way to violence, and lawless mobs known as "Fence Cutters" destroyed thousands of miles of fence. Order was restored by the executive, and many just laws enacted protecting public rights.

The Farmers' Alliance.—The unusual interest in politics among the farmers and other labouring classes resulted in several organizations. Among these was a secret society known as the Farmers' Alliance, which originated in a meeting of a few neighbours in Pleasant Valley, Lampasas county, in February 1878. In 1886 this organization had grown to a membership of from 75,000 to 100,000 in Texas and 1,000,000 in the United States. The Farmers' Alliance manifested great interest in politics, due to the general belief that the railway charges for freight were exorbitant, and antagonism towards the railway interests was intensified. The movement, however, largely died out before 1900.

State Regulation of Railways.—By 1890 an amendment to the Constitution providing for a State Railway Commission was passed. The Commission had general powers for the regulation of railways in the state by prescribing rates of freight, and was a tribunal to hear complaints made by both parties. Through a series of suits in the Federal courts, railways were compelled to make restitution for past offences. Companies were compelled to bring back their principal offices and officers into the state from foreign states to which they had been removed. Other suits broke up pooling, and recovered for the state land which had been illegally obtained. By these suits 1,437,000 acres of land were restored to the public domain. Over $3,000,000 was saved to the producers from traffic taxation alone, without diminishing the receipts of the companies.

Alien Land Laws.—An Alien Land Law, passed by the legislature, was declared illegal by the Supreme Court of the United States. The legislature then passed a modified Alien Land Act, providing that no private corporation whose main purpose was ownership of land should hereafter be allowed to acquire land in the state, and requiring that all such corporations then owning land should sell it within fifteen years.

Special Incidents.—The twenty-first legislature passed an Act to define and punish conspiracies against trade, popularly known as the Anti-Trust laws. Suits were instituted against illegal insurance companies, and stopped their business in the state. In August 1887 the state was convulsed by the so-called Prohibition campaign, when an amendment to the constitution was submitted to the people prohibiting the manufacture and sale of liquors in the state except for mechanical and scientific purposes. The proposition

was defeated by a vote of 220,627 against 129,270. The new state capitol building, commenced in March 1885, was dedicated on 16th May 1888. Parts of Texas have suffered many great natural disasters, such as droughts, storms, floods, and hurricanes. In May 1899 the Brazos river flooded the vast area of agricultural lands bordering it throughout the region of the coastal plain. In 1900 a sudden rise of the Colorado caused the breaking of a dam which the citizens of Austin had erected at a cost of more than a million dollars. On 8th September 1900 a hurricane struck Galveston, causing a loss of life estimated at 3000 and of property at twenty to thirty million dollars. The wind, which reached a maximum velocity of 96 miles an hour, piled the water of the Gulf upon the city to such an extent that every building on the sea front and for three blocks inland was destroyed, and all communication cut off.

A special session of the twenty-second legislature passed an election law providing for the registration of voters in cities of 10,000 population, known as the Australian ballot system. For years Texas had claimed jurisdiction over a tract lying in the south-west corner of Indian Territory between the forks of Red river, and had issued patents to the land therein, organized courts, and constructed school-houses and other public improvements. The Supreme Court decided that this area, known as Greer county, belonged to the United States. (R. T. H.)

Textiles.—In connexion with the history of textiles, much interest attaches to the considerable quantities of hand-woven textiles which have been discovered in Egypto-Greek, Roman, and Coptic cemeteries since 1885, and are now exhibited in many important European museums, particularly in the Victoria and Albert Museum at South Kensington. They illustrate varieties of weaving in linen and worsted threads such as were in general use amongst Greeks and Romans from the 1st and 2nd centuries before Christ up to the 8th and 9th centuries A.D., and elucidate many of those references to ancient woven fabrics which are quoted in the article on textiles in the ninth edition of this work. It is well to note that silken fabrics were practically unknown in Europe before the 1st century A.D., and anything approaching to a Western counterpart of the traditional Chinese silk manufactures, which are reported to have flourished 2000 B.C., cannot be said to have sprung into existence until the 6th or 7th centuries A.D.; after this period their development was due principally to Mahommedans or Saracens, who conquered, over-ran, and settled in many places about the Mediterranean during the 7th to the 11th centuries of our era.

The present article, however, deals with stuffs made with linen and worsted threads found in the above-mentioned cemeteries, the sites of which have been laid bare at spots adjacent to the Nile, between the district of Fayúm on the north and the town of Assuan on the south, the more notable of them being Akhmîm (or Panopolis of the Greeks) and Antinoë (or Antinopolis, founded by the Roman Emperor Hadrian). Amongst the stuffs are simple shuttle-woven fabrics, the back and front of which are alike, weft and warp threads being equally visible, as in ordinary modern sailcloths and linens of different qualities. The plain stuff of the tunic in Fig. 5 (see Plate), and the material about the angel in Fig. 2, are samples of this simple weaving. There are also materials similarly woven with woollen threads, resembling flannels. Besides these, another distinctive class of textile is that in which its back and front, and more generally the front, only are woven with loops, giving a shaggy texture, as in modern bath or Turkish towels. Indications of this are seen in the outer margins of the square (Fig. 3), and on a reduced scale in Fig. 1. This shaggy-faced material was known to the Greeks under the names of *kaunakes* or *persis*. The ancient village of Thymetes in Greece was noted in the days of Aristophanes for its manufacture of such shaggy stuffs. Hesychius writes of *kaunakes* as being *etero-malla*, or shaggy on one side only. But in Roman times Pliny "recollects the *amphi-malla* [a textile with each side shaggy] and the long shaggy apron being introduced." The main parts of the large specimen (Fig. 1) are of such shaggy material. It dates from about the 3rd or 4th century, and was probably a covering to a couch or pall. The dark ornamental portions are of compact series of worsted tufts or loops, the texture of which is kindred to that of certain carpets. Finer and similar shaggy linen-faced material was also used for tunics.

The ornamental and decorative features which abound in these different linen textiles were almost invariably made with coloured threads of linen and wool by a simple inweaving process, the method and implements of which are identical with those of tapestry-weaving by hand. The largest and most complete tapestry-weavings are the great textile pictures or storied wall-hangings of the 15th and 16th centuries made in France and Flanders (*e.g.*, Arras, Brussels), and of the 17th and 18th centuries in France (*e.g.*, Gobelins, Beauvais tapestries). Now this tapestry-weaving method of producing intricate textile ornament, but on a far smaller scale, seems to have been used by all kinds of people, and as a method was certainly much earlier in the chronology of weaving than that of figured shuttle-weaving in a loom. The widespread range of its practice amongst various people is demonstrated by specimens made by natives of Borneo, by hill tribes of India, such as the Todas, by ancient dwellers in Peru, who may have been Toltecs and Aztecs, by nomad Turcoman tribes, by Scandinavians, by Greeks of the 5th century B.C., and of course by Romans. Ovid (*Metamorphoses*, vi., 55–69) gives a remarkable and minute description of this inweaving or tapestry-weaving method; and Martial appears to be referring to work of this character when he writes that the "Babylonian needle is now surpassed by the comb of the Nile," a small comb, to press down the inwoven wefts compactly between the warp threads, being a necessary implement in this ornamental thread work. Pliny notes that "a garment when it has been worn for some time is often embellished with wool from Egypt"; and Flavius Vopiscus in the 3rd century A.D. makes mention of the "linen cloths from Egypt . . . prized on account of their laboured embroidery": these references are particularly interesting when read in connexion with the specimens which have been collected from the cemeteries above mentioned. The greater number of these textiles proves the prevalence during the earlier centuries A.D. of the tapestry-weaving process for decorating costume as well as other articles, such as hangings and coverings. The angel or winged figure (Fig. 2) bearing the segment of a wreathed cross is 2 feet 3 inches in length, and is one of a confronted pair of such figures which ornamented a cloth or hanging at least 5 feet wide. The decorative device of confronted angels occurs in large and small sculptured reliefs and other decorative work of the 1st century A.D., and prevails for many centuries later; this tapestry-woven version of it is probably of the 4th century. Of corresponding date is the panel from a shaggy-faced linen (Fig. 3). The symmetrical arrangement of the circular and curved bands marking the plan of the entire pattern is frequent in patterns of Roman mosaics. The symbols in the four outside circles are those of the Evangelists, adapted in their forms from Gnostic emblems, and possess peculiar interest as early devices of Christian iconography. Possibly of the 2nd or 3rd century A.D. is the tree and vase ornament (Fig. 4), also from a cloth. The vase is designed in a characteristic Roman style. The formal arrangement of the branches and leaves, however, reflects a conventional treatment which is met with in Egyptian wall paintings 2000 B.C. Fig. 5 gives part of an elaborately

ornamented tunic, probably of the 3rd century A.D. The double bands to the sleeve, a narrow band along the length of the tunic, square panels on the shoulder and the lower part of the skirt, and a breast enrichment are all of well-designed devices wrought in tapestry-weaving. The wide-sleeved tunic (Fig. 6), decorated with broad bands of simpler ornament, is probably of 3rd-century work. The small square (Fig. 7) is of the daintiest texture, in fine flax thread tapestry-weaving, more delicate than any later work of this character, including even fine silk tapestry-weaving from China and Japan. It is possibly of 2nd or 3rd century work, and came from a child's tunic. The colours of this, as indeed of most of the tapestry-weavings in question, are bright and fresh. Passing to quite another class of textiles, an interesting example of variegated netting as made in the 2nd or 3rd century is given in Fig. 8, which is a prototype of lace made thirteen or fourteen hundred years later. In this and other specimens of similar nettings are forestalled those varieties of meshes formed by twisting and plaiting threads which, fourteen hundred years later, became the characteristic of the grounds or *réseaux* of Brussels, Valenciennes, Mechlin, Lille, and Buckinghamshire pillow-made laces.

(A. S. C.)

Thale, a town of Prussia, province of Saxony, on the north side of the Harz Mountains, 8 miles by rail south-west of Quedlinburg, in the picturesque valley of the Bode, and in the immediate vicinity of the Rosstrappe, the Hexentanz, and other notable spots in the Harz. It has an idiot asylum, an epileptic home, and the saline springs of Hubertusbad, and there are manufactures of enamelled wares and machinery, ironworks, and breweries. Population (1885), 4498; (1900), 9467.

Thames, the chief river of Great Britain, taking its rise in several small streams on the eastern borders of the counties of Gloucester and Wilts. Its source is generally held to be at a place known as Thames Head, in the parish of Coates, 3 miles south-west of Cirencester; but claims have also been advanced on behalf of the Seven Springs, the headwaters of the river Churn, 5 miles south of Cheltenham. The Thames leaves the Gloucester and Wilts borders near Lechlade, after which it separates successively Berks and Oxford, Berks and Bucks, Middlesex and Surrey, and finally, at its estuary, Essex and Kent. Between Lechlade and Oxford it has a winding course, passing near Faringdon and Bampton. The Windrush flows into it at New Bridge, the Evenlode at Eynsham, and the Cherwell at Oxford. It then flows in a southerly direction nearly as far as Reading, receiving on the right the Ock at Abingdon, the Pang at Pangbourne, and the Kennet at Reading; on the left, at Dorchester, the Thame. After passing Reading it bends northwards to Henley, eastwards to Great Marlow, and southwards to Maidenhead, receiving the Loddon near Henley. Winding in a south-easterly direction, it passes Eton, Windsor, Datchet, Staines, Chertsey, Shepperton, and Sunbury, then receiving the Colne from the left at Staines, and the Wey from the right at Shepperton. Flowing past Hampton Court, opposite to which it receives the Mole, and past Kingston, it reaches Teddington, and at the latter place its bulk is increased by the tidal wave. At Kew the outskirts of London are reached, and it flows through the metropolis and its suburbs for a distance of about 25 miles, till it has passed Woolwich. Gravesend, the principal town below Woolwich, is 26 miles from London, and the Medway flows into the Thames estuary at Sheerness, 45 miles from London. The estuary extends to the North Foreland at Margate. In the tideway the principal affluents of the Thames are the Brent at Brentford, the Wandle at Wandsworth, the Ravensbourne at Deptford, the Lea at Blackwall, the Darenth just below Erith, and the Ingreburn at Rainham.

The length of the river from Thames Head Bridge to London Bridge is 161¼ miles, and from London Bridge to the Nore, 47¾ miles, a total of 209 miles. The width at Oxford is about 150 feet, at Teddington 250 feet, at London Bridge 750 feet, at Gravesend 2100 feet, and at the Nore 3 miles. The height of Thames Head above ordnance datum, or average sea-level, is 356 feet, and that of the river at Lechlade 237 feet, the average fall between Lechlade and London, 143 miles, being 20 inches per mile. The watershed area of the Thames is about 6000 square miles; this does not include that of the Medway, which can hardly be considered a tributary of the river.

The Thames is navigable for rowing-boats as far upwards as Cricklade, except in dry seasons, and for barges at all times as far as Lechlade, 18 miles below Thames Head. At Inglesham, three-quarters of a mile above Lechlade, the Thames and Severn Canal has its junction with the Thames. This canal is the necessary link between the two great rivers from which it takes its name, or, in other words, between the east and west of England. It was abandoned for years, but owing to the exertions of a joint-committee of the counties and other interests concerned, powers were obtained from Parliament for its restoration, and the works needful for its reopening have been carried out. Concurrently with the repair of the canal, the navigation works on the Thames were remodelled at a large cost, and barges drawing 3 feet 6 inches can now, even in the summer season, navigate from London to Inglesham.

Although the Thames, as one of the "great rivers of England," was always a navigable river, that is to say, one over which the public had the right of navigation, it was not until the last quarter of the 18th century that any systematic regulation of its flow in the upper reaches was attempted. Complaints of the obstructions in it are not uncommon, and early in the 17th century Taylor, the Water Poet, in a poem commemorating a voyage from Oxford to London, bewails the difficulties he found on the passage. No substantial measures to remedy this state of things were adopted till the year 1771, when an Act of Parliament was passed authorizing the construction of pound locks on the Thames above Maidenhead Bridge. In pursuance of the powers thus granted, the Thames Commissioners of that day caused locks to be built at various points above Maidenhead, and between 1810 and 1815 the Corporation of London carried out river works on the same lines as far down the river as Teddington. The character of these works is so well known that it is hardly necessary to explain that whilst they maintain an efficient head of water during the drier seasons of the year, they facilitate the escape of winter floods.

The canals communicating with the Thames, in addition to the Thames and Severn Canal already spoken of, are the Oxford Canal, the Wilts and Berks at Abingdon, the Kennet and Avon Canal at Reading, the Wey and Basingstoke Canals at Weybridge, the Grand Junction at Brentford, the Regent's Canal at Limehouse,

and the Grand Surrey Canal at Rotherhithe. There is also a canal at Gravesend, but this is little, if at all, used. By means of these canals, and especially by means of the Grand Junction and Oxford Canals, constant communication is maintained between the Thames and the great industrial centres of England. The importance of the merchandise traffic on the upper Thames may be estimated from the fact that in the year 1900 the sum of £10,700 was paid for tolls on barges carrying goods on that part of the river.

But considerable as is the part the river thus plays in the national economy in distribution, its usefulness is greater still in the opportunities for exercise and recreation which it affords to the public, especially to Londoners. The scene at Henley at regatta time, or on any part of the river on public holidays, and on Saturdays and Sundays during the summer, would be sufficient to show how it contributes to the public enjoyment. But a further proof is in the fact that in the year 1900 as many as 11,284 rowing-boats, 541 steam launches, and 162 houseboats were registered for use on the Thames. It is only since about 1870 that this popularity has grown up. Ten years earlier even rowing-boats were but few and far between, excepting, of course, at Oxford, at Henley in regatta time, and at Putney on the tideway. Steam launches did not exist on the river before 1866 or 1867, and houseboats only in the form of college barges at Oxford. But by the year 1884 there were 217 launches; in 1887 they had increased to 268, and in 1900 there were 541. Houseboats increased from 98 in 1887 to 162 in 1900, and rowing-boats from 8926 in 1888, the first year of registration, to 11,284 in 1900. The growth of the popularity of river sports, as shown by these figures, has been encouraged by the facilities given by the Great Western Railway and the London and South-Western Railway for reaching stations on the river, as well as by the fact that the works carried out on the river since the year 1867 by the Conservators of the Thames have much improved the navigation for pleasure purposes as well as those of business. During the season regattas of importance take place at most of the towns and larger villages. Of these Henley Royal Regatta is pre-eminent by the number and importance of the entries, and by its comparative antiquity. The regattas at Molesey, Kingston, Reading, Marlow, and Oxford, as well as many others, attract numerous competitors and spectators.

The Thames is a favourite stream for the angler—indeed, up to 1860 the angler had comparatively undisturbed enjoyment of his sport. The introduction of steam launches and the growth of traffic generally have interfered with his pursuit, but there is no reason to apprehend that, as has often been alleged, the fishery has been injured. Indeed, in the opinion of those qualified to speak, the river has as good a supply as formerly of coarse fish such as pike, perch, roach, dace, and barbel. Of trout there are many fine specimens, especially at the weirs. Salmon are known to have existed at Maidenhead so recently as 1812, but they disappeared soon after that date. An association has been formed, under the presidency of Mr W. H. Grenfell, M.P., with the object of re-introducing this fish into the river, and in April 1901 a number of young salmon were placed at Teddington by way of experiment. The right of the public to take fish has been frequently in dispute, but a committee of the House of Commons, which took much evidence on the question in the year 1884, came to the conclusion that "it is impossible to recognize anything like a general public right to take fish as now existing." They added "that the public at large have only to know that their rights are imaginary to induce them also to be content with the extant system under which permission is very freely granted by owners of fisheries to the public for angling on the more frequented parts of the Thames." These conclusions are interesting in face of the fact that the question has arisen from time to time since 1884.

The fisheries are under the regulation of bye-laws made by the Conservators of the Thames, and apply to the riparian owners as well as to the public generally. These bye-laws are carried into effect by officers of the Conservators, assisted by the river keepers of the various fishing associations. The principal associations are those at Oxford, Reading, Henley, Maidenhead, and Windsor, and last but not least, the Thames Angling Preservation Society, whose district is from Staines to Brentford.

The Thames is the principal source of the water supply of London, and the water companies of the metropolis take in the summer, the season of their greatest requirements, as much as 130,000,000 gallons a day, under the statutory powers granted them by Parliament. The companies authorized to draw water from the Thames are the Chelsea, the East London, the Grand Junction, the Lambeth, the Southwark and Vauxhall, and West Middlesex, all of which have intakes at Hampton or in its immediate vicinity. In addition to these companies, there is a joint-committee of the New River Company, the Grand Junction Company, and the West Middlesex Company, which have power to draw water when the river is above a certain level. This committee is now constructing huge storage reservoirs at Staines Moor. Outside of London the corporation of Oxford and two small companies in the Staines district have power to draw water from the river, but not in any large quantities.

The flow of the Thames varies greatly, according to the season of the year. The average gaugings at Teddington for the summer months of the years 1883 to 1900 were in July 413,000,000 gallons a day, in August 395,000,000 gallons, and in September 375,000,000 gallons. At present the normal natural flow in ordinary summer weather is about 350,000,000 gallons a day, and of this, after the companies have taken 130,000,000, only 220,000,000 gallons are left to pass over Teddington Weir. After a long period of dry weather the natural flow has been known to fall to considerably below 200,000,000 gallons, whilst, on the other hand, in the rainy winter season, the flow in 1894 rose for a short time to as high a figure as 20,000,000,000 gallons, and the ordinary flow in winter months may be put down as 3,000,000,000 gallons. The importance of storage reservoirs, such as those at Staines, is manifest under such conditions of flow, especially bearing in mind the probable growth of population in the London district and of its increasing needs.

Whilst the flow of the river requires the most careful observation and regulation, as well in the interest of the traffic as of the water supply itself, the preservation of the purity of the stream calls for even more assiduous attention. Throughout the whole of the Thames watershed, and especially in the 3800 square miles above the intakes of the water companies, the Conservators have enforced the requirements of Parliament that no sewage or other pollution shall be allowed to pass into the Thames, into its tributary streams, or even into any water communicating with them. There is a large staff of inspectors constantly visiting the various parts of the watershed, and in spite of many difficulties arising from vested interests, the work of purification is attaining completion, with a correspondingly great improvement in the quality of the river water. So recently as 1890 the state of the river below London was such as to be dangerous to the public health. The metropolitan sewage was discharged untreated into the river, and the heavier solids deposited over the river-bed, while the lighter parts flowed backwards and forwards on the tide. The London County Council, directly after its establishment, took means to remedy this evil, and the solids are now separated from the sewage and taken to sea in large steam hoppers. The liquid effluent passed into the river does not now give rise to complaints, but the Council are, notwithstanding, carrying out works of magnitude to secure that the effluent shall be above suspicion.

While the points already dealt with are of very great interest, nothing has been said of the trade which constitutes the real importance of the Thames. Early in the 16th century the opulence of London, and the extent of the trade on the Thames, evoked the admiration of the ambassadors of Venice, and the port continued to hold its position in the following centuries. At the end of the 18th century the business of the port received a considerable impetus, due doubtless to the marked superiority of Great Britain at sea. The House of Commons in 1796 considered the growth of the trade in the port of London of such importance as to call for the appointment of a strong committee of the House to deal with the question of improvements to be made, and of this committee Mr Pitt, Mr Fox, and Mr Sheridan were members. Yet it is probable that at that date the trade of the port did not exceed 1,500,000 tons a year. The total foreign inward and outward trade of the port in the year 1816 amounted to only 1,240,000 tons; if to this be added as much again for coasting trade, we have a total trade of 2,500,000 tons. In 1850 the total trade, foreign and coasting, had grown to 7,494,815 tons; in 1870 to 11,169,746 tons; in 1890 to 20,962,334 tons; and in 1900 it approximated to 30,000,000 tons.

The greater part of this trade proceeds up the river to the various docks, of which the most important are the Tilbury Dock, the Albert Dock, and the Victoria Dock belonging to the London and India Docks Company, the Surrey Dock and the Commercial Dock, both belonging to the Surrey Commercial Dock Company, and the Millwall Docks. Ships of the largest draught can be docked in the Albert and Victoria Docks, in which the steamers belonging to the Peninsular and Oriental Companies, the Union-Castle Company, and other great lines load and discharge. The Surrey and Commercial Docks are mostly used for the timber and corn trades. The use of the river and the docks by the great ocean-going steamers has given rise to discussion as to the depth of the river and the necessity of dredging to a much greater extent than in the past. The river has been deepened to 26 feet up to Gravesend, and dredging to 22 feet is being carried out up to the Albert Docks. These depths are considered by the owners of large steamers to be insufficient, and they maintain that a depth of 30 feet at low water to Gravesend and of 26 feet to the Albert Dock is the least that should be afforded.

The regulation of the traffic below London is under the control of harbour-masters appointed by the Conservators, and it is part of their duty to see that the laws relating to explosives and to petroleum are duly observed. An important detail of the work in

the river is the removal from the stream of sunken vessels. Of these forty or fifty are generally dealt with every year, many of them being large steamers. In most cases they are delivered to their owners on payment of the comparatively small expense incurred in raising.

There has existed from early times a special authority for the government of the Thames. A statute as far back as 1393, the 17th Richard II., cap. 9, recites that it had been granted to the citizens of London by the king's progenitors to remove all the weirs on the waters of Thames, and to leave the punishment thereof relating to the king, and it then grants to the Lord Mayor the enforcement of the particular provisions of the statute itself. The Lord Mayor for the next four centuries after the date of the statute enforced his powers through the medium of his water bailiffs, till, in 1771, a committee of the Corporation of London took under their charge the details of the work. This system continued till 1857, when an Act of Parliament was passed establishing the Thames Conservancy Board. The powers of this body have been enlarged by subsequent Acts of Parliament, and its constitution was varied in 1864 and 1866, and again in 1894, when it was greatly increased in numbers and placed on a more popular basis. The jurisdiction of the river above Staines was formerly under a very numerous body of commissioners, and was only transferred to the Conservancy Board in the year 1866.

A word should be added on the name of the Thames. Camden gave currency to the derivation of the word from the combination of the names Thame and Isis. Now it can be shown conclusively that the river has borne its present designation from the earliest times. We have the testimony of Cæsar (*B.G.*, v. 11) who says that at the time of his invasion of Britain it was called Tamesis. Dion Cassius (xl. 3) and Tacitus (*Ann.* xiv. 32) both call it Tamesa, and in no early authority is the name Isis used. In early Saxon times the river was called Thamis, as may be seen in a grant before A.D. 675 to Chertsey Abbey by the sub-king Frithwald. In the first statute passed for improving the navigation of the river near Oxford (21 Jac. I.) it is called the river of Thames, and it was only in a statute of George II. (1751) that the word Isis appears. The name Isis has indeed the authority of Spenser as applied to the Thames in its course above Dorchester (*Faerie Queen*, Bk. iv. canto xi. stanza 24), but there is ample evidence to show that long before his time the name of the river throughout its course was not Isis but Thames. The word Isis is probably an academic rendering of Ouse or Isca, a common British river name, but there is no reason to suppose that it ever had much vogue except in poetry or in the immediate neighbourhood of Oxford.

See *Ordnance Survey of England* for physical features; Report of the Select Committee of the House of Commons on Thames River Preservation, 1884; Reports of Royal Commissions of 1892 and 1898–99 on Metropolitan Water Supply; Evidence given before the Royal Commission on the Port of London, 1900; Annual Reports of the Conservators of the River Thames; Minutes of the London County Council. (J. H. Go.)

Thana, or TANNA (=a fort, or police-station), a town and district of British India, in the Konkan division of Bombay. The town is on the west of the Salsette creek or Thana river, just where the Great Indian Peninsula railway crosses to the mainland, 21 miles from Bombay city. Population (1881), 14,456; (1891), 17,455; (1901), 16,011.

The district of THANA, since the census of 1891, has been diminished by the transfer of about 200 villages to Kolaba. Present area, 3578 square miles; population, 819,580, showing an average density of 229 persons per square mile. In 1901 the population was 809,361, showing a decrease of 1 per cent. The land revenue and rates are Rs.15,08,077, the incidence of assessment being R.1.4.10 per acre; number of police, 1052; children at school (1897–98), 15,046, being 1·98 per cent. of the total population; registered death-rate (1897), 37·10 per 1000. Cultivated area (1897–98), 453,684 acres, of which 4593 were irrigated from wells. The staple crop is rice. Fishing supports many of the people, and the forests yield timber and other produce. Salt is largely manufactured by evaporation along the coast. At Kurla, in Salsette Island, there are 2 cotton mills, with 915 looms and 54,000 spindles, employing 4370 hands; 4 rice mills; 4 printing-presses, issuing 4 vernacular newspapers. The district is traversed throughout its length by the Bombay and Baroda Railway, and also crossed by the two branches of the Great Indian Peninsula line.

Thann, a town of Germany, in Alsace-Lorraine, district of Upper Alsace, 16 miles by rail west-north-west of Mülhausen. It is the seat of cotton, calico, silk, machinery, and other industries. An excellent wine is made. The (Roman Catholic) church of St Theobald (1351) is an elegant specimen of the Gothic, and has a remarkably fine tower (1450–1516), 266 feet high. Above the town are the ruins of the castle of Engelburg, destroyed by Turenne in 1675. The town existed in the 10th century. Population (1885), 7464; (1900), 7618.

Thar and Parkar, a district of British India, in the Sind province of Bombay. Area, 2729 square miles; population (1881), 203,344; (1891), 298,203, showing an increase of 47 per cent., due to the extension of irrigation; average density, 23 persons per square mile, compared with 60 for Sind generally. In 1901 the population was 364,168, showing a further increase of 22 per cent.

The land revenue in 1897–98 was Rs.8,33,038, the incidence of assessment being R.1.7.3 per acre; cultivated area, 767,786 acres, of which 320,538 were irrigated from Government canals; number of police, 515; children at school, 3123, being 1·1 per cent. of the population; registered death-rate (1897), 19·54 per 1000. The principal crops are millet, rice, oil-seeds, and cotton. Cultivation largely depends upon the control of the water which comes down the canals and occasionally causes flood. Salt is found in two or three places. The western border of the district is entered by the railway from Haidarabad to Shadipalli, connected with the North-Western main line by a bridge across the Indus at Kotri, and with the Rajputana system at Jodhpur.

Umarkot, the administrative headquarters of the district, is on the edge of the desert. Population (1881), 2828; (1891), 3702. Historically interesting as the birthplace of the emperor Akbar in 1542, it is now a station on the railway from Haidarabad to Jodhpur, which has brought central India into direct connexion with the seaport of Karachi.

Tharandt, a town of Germany, romantically situated on the Wilde Weisseritz, 8¾ miles S.W. of Dresden, kingdom of Saxony, on the Dresden–Reichenbach railway. It has a Protestant church, a higher-grade girls' school, and the oldest academy of forestry in Germany, with about 90 students. Tharandt is a favourite summer resort of the Dresdeners, one of its principal charms being the magnificent beech woods which surround the little town. Population (1900), 2822.

Tharrawaddy, a district of the Pegu division of Lower Burma, lying to the north of Rangoon. Area, 2851 square miles; population (1891), 339,240, living in 1458 villages; (1901), 395,870. They paid in 1898–99 a revenue of Rs.13,15,648.

Of the population in 1891, 329,688 were Buddhists and Jains, 2843 were Hindus, 1674 Mahommedans, 1877 aborigines, mostly Karens, and 3158 Christians, 2722 of whom were natives, most of them Karens. Of the total area of 1,824,640 acres, 402,222 acres were cultivated in 1898–99. The remainder was made up of forest land, 616,669 acres; land not available for cultivation, 243,421 acres; cultivable waste, 544,918 acres; and current fallow, 17,410 acres. The rainfall in 1898–99 was 81·61 inches. The railway runs through the centre of the district, and there are ten railway stations. The chief villages, with their population in 1891, are Zigôn, 1256; Gyobingauk, 2960; Thonzè, 1653; Letpadan, 1575. The great bulk of the cultivation is rice.

Thatôn, a district in the Tenasserim division of Lower Burma. Area, 5089 square miles; population (1891), 266,620; (1901), 340,355. It was formerly a subdivision of the Amherst district, but was formed out of part of that and of the Shwegyin district which has now ceased to exist. There were 922 villages in 1898–99, and they paid a revenue of Rs.15,36,381.

The population was made up in 1891 of Buddhists and Jains, 247,662; aborigines, mostly Karens, 7338; Hindus, 6092; Mahommedans, 3814; and Christians, 1714, most of them natives. Of the total area of 3,256,890 acres, 529,826 acres were cultivated in 1898–99. Of the remainder 152,031 acres were forests, 1,750,703 were uncultivable, 811,590 were available for cultivation, and there were 12,740 acres of current fallow. The rainfall in 1898–99 was 181·84 inches. The headquarters town THATÔN had a population of 9683 in 1891. The great bulk of the cultivation is rice, but a good deal of tobacco also is grown.

Thaxter, Celia (1836–1894), American poet, was born at Portsmouth, New Hampshire, 29th June 1836. Her father, Thomas B. Laighton, became offended with some of his associates in state politics, and retired to the barren and isolated Isles of Shoals (ten miles off Portsmouth), where he was keeper of the lighthouse; and his daughter's girlhood was therefore spent in marine surroundings, which gave character to the best of the verse she afterwards wrote. Her poems, mainly in lyrical form, deal with the beacon-light, the sea-storm, the glint of sails, the sandpiper, the flower among the rocks, &c., in characteristic and sympathetic fidelity, constituting an interesting addition to American place literature. She wrote prose sketches of life and scenery, *Among the Isles of Shoals* (1873), stories and poems for children, and letters; but her best work is that described above, and contained in the complete (1896) edition of her poems, edited by Sarah Orne Jewett. She married Levi L. Thaxter, an interpreter of Browning's poetry, in 1851, spent most of her life on Appledore, one of the Isles of Shoals, and died 26th August 1894.

Thayetmyo, a district in the Minbu division of Upper Burma. It was formerly in the Irrawaddy division of Lower Burma, but was transferred to Upper Burma for administrative purposes in 1896. Area, 4750 square miles; population (1891), 250,161, living in 939 villages, and paying a revenue of Rs.4,03,504; (1901), 239,877.

The population was made up in 1891 of Buddhists and Jains, 226,732; aboriginal tribes, mostly Chins, 17,291; Hindus, 2524; Mahommedans, 2149; and Christians, 1465, of whom 545 were natives. The area is 1,534,080 acres. Of this in 1898–99 only 112,146 acres were cultivated, 296,320 acres were under forests, 564,928 acres were not available for cultivation, 544,535 acres were cultivable, and there were 16,151 acres of current fallow. The total rainfall in 1898–99 was 26·3 inches. The chief towns are Thayetmyo and Allanmyo, on opposite banks of the Irrawaddy. In 1891 Thayetmyo had 17,101 inhabitants, and Allanmyo 9012. There is now only a wing of a British regiment stationed here. There is a central gaol capable of containing 1214 prisoners. The bulk of the cultivation is rice, but in 1898–99 there were 3935 acres under tobacco. There are 256,256 acres of reserved forest. Three oil-wells were sunk in 1883 at Pedaukpin, but they were found unprofitable and abandoned.

Theinni, called by the Shans Hsenwi, and also officially so designated, but better known by the Burmanized name of Theinni. It was by far the largest of the cis-Salween Shan states, and at one time included not only all the territory of the present states of North and South Hsenwi, but also Kehsi Mansam, Möng Hsu, Möng Sang, and Mong Nawng, besides having a sort of protectorate over Mang Lön and other Wa states east of the Salween. These had, however, fallen away in Burmese times, and at the period before the British annexation Theinni was divided into five parts by name; but there was no central authority, and the whole state was in hopeless disorder. This continued until the appearance of British troops in March 1888, when it was divided into two states—North Theinni, which was assigned to a successful adventurer, Khun Hsang, of Tôn Hông, and South Theinni, which went to Nawmöng, of the old Shan ruling house. North Theinni has an approximate area of 6330 square miles, and a population estimated at 118,000 persons, living in 1500 villages, divided among 76 districts. South Theinni has an approximate area of 5000 square miles, and a population estimated in 1897 at 57,223.

The northern part of North Theinni is a mass of hills affected by the geological fault which has produced the rift that forms the Nam Tu or Myit-ngè valley, and has thrown up a series of parallel ranges which extend northwards to the Shweli (Lung Kiang), without altogether destroying the north and south trend which is the characteristic of the Shan hills as a whole. In the valleys between these hills are numerous tracts under rice cultivation, some circular or oval, some mere ribands along the river banks. The southern portion has much more flat land, along the line of the Nam Tu, its tributaries the Nam Yao and the Nam Nim, and the Nam Yek flowing into the Salween. This was formerly thickly populated, and still remains the most valuable portion of the state. A range running westwards from the Salween, and marking the southern border of the rift in the hills, divides North from South Theinni. Both north and south of the Nam Tu there are many peaks which rise to 6000 feet, and several over 7000 feet. The northern portion is almost consistent enough in its altitude of about 4000 feet to be called a plateau. It has large, grassy, upland downs. This part of the state has fallen almost entirely into the hands of the Kachins. The Shans are found in the Nam Mao (Shweli or Lung Kiang) valley, and in the Nam Tu and other valleys in the southern part of the state. The line of the Nam Mao is the lowest portion of North Theinni, being little over 2000 feet above sea-level. The southern valleys are about 500 or more feet higher. South Theinni is practically bisected by the huge mass of Loi Ling, nearly 9000 feet above sea-level, and by the spurs which that peak sends north and south. Apart from this it consists of broken hill-country of no great height, or open rolling downs, the latter chiefly in the eastern half of the state. It is watered by numerous streams, of which the chief is the Nam Pang, an affluent of the Salween. The chief river in the northern state, apart from the Salween, is the Nam Tu or Myit-ngè, which rises on the Irrawaddy–Salween watershed, not far from the latter river, and flows westwards through the state into Taungbaing or Thebaw, and eventually into the Irrawaddy at Amarapura. The Nam Mao or Shweli only skirts the state, but it receives a considerable tributary, the Nam Paw, which has its entire course in Theinni territory, and is large enough to be barely fordable in the dry weather, and only passable by boats in the rains. The deforestation caused by years of upland cultivation has dried up many of the springs, but as a whole North Theinni is very well watered. Considerable deposits of coal, or rather of lignite, exist in both North and South Theinni, but do not appear to be of high quality. Gold is washed in many of the streams in a fitful way. Limestone exists in large quantities. No valuable timber exists to any considerable extent. There is some teak in the Nam Yao valley, and scattered wood-oil trees exist. Pine forests cover some of the ranges, but, as elsewhere in the Shan states, varieties of the oak and chestnut are the commonest forest trees. The climate of the state as a whole is temperate. In the plains of the uplands there are yearly frosts in January, February, and March, but in the greater part of the state the thermometer rarely falls to freezing-point, and in the hot weather does not exceed ninety degrees for any length of time. The average rainfall seems to be about 60 inches yearly. After the disruption of the ancient Shan empire at Tali by Kublai Khan, Theinni seems to have been the centre of the independent Shan kingdom, with various capitals in the Shweli and Nam Tu valleys. This kingdom of Kawsampi was ended by the Burmese about 1738, and the country was divided into various states, with appointment orders from Ava. Numerous rebellions and civil wars have reduced Theinni from its position as the most powerful and populous Shan state to a condition of fearful desolation. It has regained much population since the British occupation in 1888, but is still far from its old prosperity. Much may be expected from the cart roads that have been made, and from the Mandalay–Kun Lông Railway.

Hsenwi, the capital of North Theinni, contained 150 houses in 1898, with a population of about 800. It stands near the north bank of the Nam Tu. The ruins of the old capital lie at a short distance, and show it to have been a large and well-built town, with a number of houses variously estimated at from three to ten thousand. Möng Yai is the capital of South Theinni. It numbered 481 houses in 1897, with about 2000 inhabitants in the town and suburbs. Lashio, the headquarters of the Superintendent of the Northern Shan State, is in North Theinni. The races found in Theinni comprise Shans, Kachins, Chinese, Burmese, Lihsaws, Wa, Palaungs, and Yanglam. The Shans and Kachins vastly predominate, and are nearly equal in numbers. (J. G. Sc.)

Theiss (Hungarian, *Tisza*), a large affluent of the Danube, next to which it is the greatest river of Hungary. It springs in the north-eastern part of the Carpathian Mountains, in the county of Máramaros, at a height of above 2000 metres. By a quick fall it soon reaches the great Hungarian plain (Alföld), where it becomes slow, somewhat muddy, and very tortuous. It flows into the Danube near Titel. Its length from source to mouth is, as the crow flies, only 455 kilometres, but its windings make its course about 1000 kilometres long. The floods formerly spread far and wide and caused immense damage; and in 1879 the town of Szegedin was almost destroyed by

an inundation. Therefore the river is now strongly dammed. Formerly the Tisza and its tributaries were fabulously rich in fish, but these have considerably diminished. There are numerous water-mills on the stream, which is navigable for rafts almost everywhere, but for steamers only downwards from Szolnok for a length of 338 kilometres. Its chief tributaries are the Szamos, Körös, Maros, Latorcza, and the Sajó. In its lower course it is joined to the Danube by the Francis-Joseph canal crossing the county of Bács-Bodrog. A canal connecting Budapest with the Tisza is projected. As a purely Hungarian river, having its entire course within the frontiers of the country, the Tisza plays a considerable part in Hungarian literature and popular poetry.

Theodosia (formerly KAFFA), a seaport and watering-place of Russia, on the south-east coast of Crimea, 75 miles by branch line from Jankoi junction on the Sebastopol Railway, and 181 miles from Sebastopol. Its roadstead is the best in Crimea after Sebastopol, and very seldom freezes in winter. It has gained much of the trade of Sebastopol since that town was made a military port in 1894, and the value of its exports, principally grain and animal products, is increasing year by year. Population (1897), 27,238.

THERAPEUTICS.

THERAPEUTICS is that branch of medicine which deals with the means employed to cure disease if possible, or to control and lessen its evil results when a cure is impossible. The cure which is sought for may either be symptomatic or radical. Various morbid conditions of the body generally may give rise to different symptoms. Thus a gouty condition may manifest itself in one man as eczema of the skin, giving rise to redness and intense itching; in another as neuralgia, causing most severe pain; in a third as bronchitis, producing a distressing cough; in a fourth as dyspepsia, giving rise to flatulence and intestinal disturbance; and in a fifth as inflammation of the great toe, accompanied by redness, swelling, and pain. The therapeutic measures employed in these different cases may be directed towards alleviating the symptoms, such as itching, pain, cough, and swelling, in which case the treatment will be merely *symptomatic;* or they may be directed towards removing the root of the disease, viz., the gouty condition underlying them all, and thus effecting a *radical* cure. It very frequently happens that we do not know what the underlying condition is, and we are forced simply to relieve as best we can the most prominent and most distressing symptoms. In symptomatic treatment we are frequently obliged to use remedies simply because we know they have done good before in similar cases, and we expect them to do so again without having the least idea of how they act. Thus in acute gout the most common and most trusted remedy for removing the pain is colchicum, but at present we do not know what action it has upon the system, or why it gives so much ease in the pain of gout while it has comparatively little effect upon pain due to other causes. This plan of treatment is termed *empirical.* It is a useful method, and is often very satisfactory, but it has the disadvantage that it admits of but little progress, and when a trusted empirical remedy fails we do not know precisely in what direction to look for a substitute. In contradistinction to empirical we have *rational* therapeutics, by which we mean the application of a remedy whose mode of action we know more or less perfectly in diseased conditions, the nature of which we also understand more or less fully. As an example may be taken the use of nitrite of amyl in angina pectoris. It has been found that in many cases of this disease the pressure of blood within the arteries becomes increased, probably from spasmodic contraction of the arteries themselves. Nitrite of amyl has the power of dilating the arteries; it has consequently been employed with much success in lowering the blood pressure and removing the pain in angina pectoris. But such rational knowledge as this not only enables us to remove pain at the time, but helps us to prevent its recurrence. For on the one hand knowledge of the fact that nitrite of amyl lessens blood pressure has led to the successful employment of other nitrites and bodies having a similar action, and on the other the knowledge that increased blood pressure tends to cause anginal pain leads to the prohibition of any strain, any food, any exposure to cold, and also of any medicines which would unduly raise the blood pressure. Here we notice one of the greatest advantages of rational over empirical therapeutics. In cases of angina, while the resistance opposed to the action of the heart by spasm in the vessels may be great, the heart itself may be feeble, and it may therefore be necessary to give some remedy which will increase the power of the heart. But if such a remedy were given alone it might, and probably would, act on the arteries as well as the heart, and by causing the contraction of the vessels do more harm than good. But if we know what remedies will increase the power of the heart and what will lessen resistance in the vessels, we may combine them and thus obtain the objects we desired, viz., removal of the pain, better action of the heart, and more perfect circulation.

Empirical and Rational treatment.

The testing of ideas by observation and experiment which was begun in anatomy by Vesalius, and by Harvey in physiology, was applied by Morgagni to alterations in the organs produced by disease, by Bichat to the tissues, and by Virchow to the cell. The study of disease in the living body may be said to have been begun by John Hunter (*Ency. Brit.*, 9th edition, i. p. 815, xii. p. 385, xv. p. 816, xxii. p. 676), developed by Magendie, Claude Bernard, Brown-Séquard, and others. Of late years enormous impulse has been given to our knowledge of the causation of disease by microbes, through the works of Gaspard, who injected putrid matter into the veins of a living animal; by Villemin, who discovered that tuberculosis is infective; by Davaine; and especially by Pasteur, Koch, and others too numerous to mention, who have worked, and are still working, at the microbic causation of disease with marvellous success. The natural end of life is that all the organs should become old and gradually decay at the same time, so that at the last the individual should become less and less active, weaker and weaker, and finally die without any definite disease, without pain and without struggle. But this is exceptional, and generally one part gives way before another, either on account of one part being naturally weaker or of one part having been overtaxed or more severely attacked by some injurious external influence, or by some undue preponderance of another part of the body itself. For health consists in a due proportion between the action of all the different parts of the body, and if one part be unnaturally strong it may lead to injury or death. Thus

Harvey's successors.

a very strong heart, although it may be useful to its possessor for many years, driving the blood rapidly through the vessels, and supplying all his tissues with such abundant nutriment as to enable him to endure great exertion, mental or bodily, may in the end cause death by bursting a vessel in the brain, which might have resisted the pressure of a feebler circulation for years longer. On the other hand, a heart that is too feeble may cause its owner's death by its inability to carry on the circulation against increased resistance. This may occur suddenly, as when the resistance is increased in the arterial system by a sudden exertion or strain, and more slowly when the resistance is increased in the pulmonary circulation by inflammation of the respiratory passages. The thyroid gland, which is situated in front of the neck, yields a secretion which passes into the blood and there tends to maintain a state of moderate dilatation in the blood-vessels and of oxidization in the tissues, so that the circulation remains good and the body-heat and muscular activity remain well maintained. When this gland becomes enlarged, and its secretion consequently increases, the vessels dilate, the heart beats more rapidly, the skin becomes too hot, the nervous system becomes irritable, and tremors occur in the limbs. On the other hand, when it becomes atrophied the circulation becomes feeble, the face heavy and dull, the patient suffers from cold, the features grow lumpish, mental processes become sluggish, and bodily vigour diminishes.

Disease by feebleness or excessive action of one part of the body.

Disease of the whole body may thus be produced by over-action or under-action of some part of it, but such causes of disease are slight as compared with the effect of external noxious influences, and more especially the effect of microbes. These enter the body through various channels, and once they have effected a lodgment they grow, multiply, and give rise to various poisons which attack and injure or destroy different tissues or organs in the body. Various safeguards are provided by Nature to prevent their entrance. On the skin we have a thick epidermis through which microbes cannot pass, although if an entrance is obtained for them by a prick or cut they may readily grow in the tissues below and spread from them throughout the whole body. They pass more readily through mucous membranes, but almost every one of these is provided not only with a coating of mucus, which obstructs their passage, but with some reflex mechanism which tends to remove them. Thus irritation of the eye causes winking and secretion of tears, by which the irritant is removed; irritation of the nose causes sneezing; of the air-passages, coughing; of the stomach, vomiting; and of the intestines, diarrhœa. Even when they have passed through the mucous membranes and enter the blood they are met, in some instances, by a toxic action of the blood itself upon them; and in others they are attacked by the white corpuscles, which destroy them, eat them up, and digest them, the process being known as phagocytosis. Moreover, the products of microbic secretion tend to produce fever. The high temperature characteristic of this condition is no doubt injurious to the body itself, but it is frequently more so to the microbe which has invaded the organism; and thus fever, instead of now being regarded as a morbid condition to be suppressed by every means in our power, is considered to be a reaction of the organism tending to protect it by destroying the infection. But it must be kept within limits, lest it should of itself cause death, and here again we see the difference between empirical and rational medicine.

Microbes.

Fever is not to be looked upon as an unmitigated evil, to be removed if possible, but rather as a defensive mechanism by which the organism may prevent invasion from noxious microbes. Nevertheless, as in a campaign the general's plan may be spoiled by too hasty or too eager action on the part of some of his troops, so the defensive arrangement carried to excess may prove injurious or fatal to the organism. Thus too great a rise of temperature in fever may kill the patient; and the aim of therapeutics is to restrain the temperature within proper limits, neither allowing it to rise too high nor to fall too low. The old plan of lowering it by means of cold baths was known to Musa, the physician of Augustus, and by it he saved the emperor's life; but the same treatment killed the emperor's nephew.

The introduction of the clinical thermometer, which allows us to ascertain exactly the amount to which the temperature rises in fever or to which it is reduced by antipyretic measures, is to the physician like the compass to the sailor, and allows him to steer safely between two extremes (HYDROPATHY, *Ency. Brit.*, 9th edition, vol. xii.). After the struggle between the organism and the microbes is over, even when it has ended victoriously for the former, injuries are left behind which require repair. Every one has noticed after prolonged fever how thin and weak the patient is, and both the muscular and nervous power throughout the whole body are sadly in want of repair. Where there has been local mischief due to inflammation the dead leucocytes must be removed, and this is done either by their being converted into pus in one mass (PATHOLOGY, vol. xviii. pp. 365 and 400), and making their way through the tissues to the nearest surface, whether of skin or mucous membrane, from which it can be discharged, or they may undergo a process of fatty degeneration and absorption, leaving behind in some cases cheesy matter, in others hard connective tissue.

Poisons formed by microbes are partly eliminated by the kidneys, partly by the mucous membrane of the stomach and intestines, and possibly also by the skin. In days of old free elimination by these channels was looked upon as a sign of returning health, and was termed a "critical" diuresis, diarrhœa, or sweating, according to the channel through which the eliminative act had occurred.

By therapeutic measures we strive to limit as far as possible the entry of injurious microbes into the organism, to expel or destroy them and their harmful products, and to maintain the strength of the organism itself. One of the influences which is most injurious to the body, and favours most the invasion of microbes, is chill. So much is this the case that some diseases which are now known to be due to infection were formerly attributed entirely to the effect of cold. Thus pneumonia is now known to be due to the diplococcus pneumoniæ, and yet its invasion occurs so frequently after a chill that it is almost impossible not to look upon chill and pneumonia as cause and effect. The reason of this appears to be that the diplococcus is frequently present in the mouth or air-passages without giving rise to any symptoms; but when the patient is exposed to chill, and the tissues of the respiratory passages are thereby weakened, the diplococcus grows, multiplies, and gives rise to inflammation of the lungs. Even what are known as common colds are probably due chiefly to microbic infection aided by a chill, just like pneumonia. Therapeutic measures which are commonly adopted in the treatment of a cold have for their object to destroy the microbes before they penetrate fairly into the organism, and to restore the balance of the circulation and increase the strength of the invaded parts. Thus carbolic acid or carbolized ammonia are sniffed into the nose to destroy the microbes there, or the nose is washed out by an antiseptic solution as a nasal douche; bismuth or morphine are insufflated, or zinc ointment is applied, to cover the

mucous membrane, and protect it from further irritation; and various antiseptic gargles, paints, and powders applied to the pharynx in order to prevent the microbic inflammation from extending to the pharynx and down the trachea and bronchi, for many a severe bronchitis begins first by sneezing and nasal irritation. Sometimes the patient is put to bed and the circulation is encouraged, especially on the surface of the body, by the use of hot spirits and water, or opium and ipecacuanha (DIAPHORETICS, *Ency. Brit.*, 9th edition, vol. vii.), while the outside of the nose is protected to a certain extent from loss of heat, and consequent irritation, by smearing it with a tallow candle or rubbing some ointment over the skin. At the same time, if the throat has begun to show signs of being involved, a hot poultice or wet pack is applied to the neck.

Both inflammation and fever are protective processes calculated to defend the organism against the attacks of microbes. But protective processes misdirected or carried to excess may become injurious or even dangerous to the organism. As an instance of misdirection, we may take the irritation which remains in the eye after a particle of dust has been removed, or the itching of the skin which occurs in eczema. The irritation of the conjunctiva caused by dust leads to winking of the eyelids, lachrymation, and rubbing, which tend to remove it; but after the dust has been removed violent rubbing tends rather to keep up the irritation; and sometimes, if the particle of dust remains under the eyelid and is sharp and angular, the process of rubbing may cause it to injure the conjunctiva much more than if it were left alone. In the same way itching is often caused by the presence of insects or other irritants upon the skin, and it tends reflexly to cause rubbing, which is useful by removing the irritant. But when the irritation is situated in the skin itself, as in eczema, the scratching tends to increase inflammation, and makes the irritation worse. In the same way, the reflex act of coughing is useful in removing either foreign bodies or excessive secretion from the air-passages; but when the mucous membrane of the respiratory tract is irritated and inflamed, it produces a feeling of tickling and a desire to cough sometimes very violently; yet the coughing simply tends to exhaust the patient, because there is really little or nothing to bring up. The same is the case in inflammation of the lung substance itself. As an example of excessive action we may take sneezing, which is calculated to remove irritants from the nose, but when too powerful may cause the patient to burst a blood-vessel. In phthisis also, although there may be some expectoration to bring up, yet a good deal of the irritation is in the lung substance, and the efforts of coughing are far greater and more continuous than are required for the removal of expectoration, and they simply exhaust the patient. In inflammation of the stomach also such continuous vomiting occasionally occurs that the patient's life is in danger by his inability to retain food; and similar danger also occurs from inflammation of the intestines and consequent diarrhœa.

We will next take the various parts of the body, and consider more in detail the therapeutic measures most commonly employed in the treatment of their diseases. The defensive powers of the body against microbes, when actually on or in it, may be classed as means (1) of passive defence, (2) of active defence, and (3) of repair. Besides these, however, we must consider the protection of the whole body from injury caused by (*a*) inaction, (*b*) or over-action, or (*c*) weakness of any one of its parts. The means of passive and active defence are sometimes so closely associated that it is difficult to distinguish between them. Thus if a little diphtheritic sputum were coughed into a person's eye, or some blood containing anthrax bacilli were to touch a raw spot upon the hand, the removal of microbes in either case by washing with simple water might be regarded as a means of passive defence, whilst washing them away with an antiseptic lotion might be regarded as active defence, because the antiseptic would tend not only to remove but to destroy the microbes. In the same way, washing the skin with spirit would tend to harden the epidermis and thus prevent the entrance of microbes; and the application of an ointment to an abrasion would have a similar action. But by the addition of some antiseptic to the ointment its defensive action would be converted from passive to active, and its power to prevent infection would become greater; and if inflammation had already set up in the skin, the addition of opium, belladonna, or cocaine would lessen local pain; and an astringent, either metallic or organic, would restrain inflammation and accelerate repair. The thickening of the epidermis in the hands and feet, which occurs from constant use, is Nature's provision for meeting the extra wear to which these parts are subjected by much use; but pressure is apt to cause the defensive process to be carried too far, and to lead to corns, which give rise to much pain and annoyance. To remove these salicylic acid dissolved in flexible collodion is now generally employed. When this is painted upon the part the corn usually peels off in a day or two, and the patient is cured.

Defensive measures.

But the object of therapeutics is not merely to cure. It is, in the words of the old formula, "Curare, cito, tuto et jucunde," to cure quickly, safely, and pleasantly. There are therefore in most prescriptions (1) a basis or chief ingredient intended to cure (*curare*), (2) an adjuvant to assist its action and make it cure quickly (*cito*), (3) a corrective to prevent or lessen any undesirable effect (*tuto*), and (4) a vehicle or excipient to make it suitable for administration and pleasant to the patient (*jucunde*). In the remedy just mentioned the salicylic acid forms the basis; but sometimes chloride of zinc or lactic acid is added to it to make it act more quickly, and these are the adjuvants. Extract of belladonna is added to lessen the pain which might occur during the removal of the corn, and this acts as a corrective, while the flexible collodion forms a means of applying it conveniently, and constitutes the vehicle.

Principles of cure.

The surface of the skin may be invaded by parasitic organisms and may exhibit spots, which are removed by something which will destroy the parasite, such as ointments containing mercurial salts. In psoriasis the epidermis separates in flakes at various spots which have not been subjected to pressure, and to cure it ointment containing tar or other products of the dry distillation of wood is employed. When the true skin is inflamed various appearances may arise, according to the intensity and extent of the inflammation, and the eruption may be papular, vesicular, pustular, tubercular, bulbous, or ulcerative. To lessen irritation the skin is protected by dusting powders, such as oxide of zinc, starch, fuller's earth, &c., or by ointments. Irritation is lessened by lotions containing substances that will diminish irritability of the nerve-endings and skin, such as carbolic acid, hydrocyanic acid, morphine or opium, cocaine, belladonna or atropine. Where the surface is ulcerated it may be protected from external violence and placed under favourable conditions for healing by covering it with lint moistened with water and with oil-silk over it to prevent evaporation. If the granulations tend to become too abundant, some astringent, such as sulphate of copper or sulphate of zinc, is added to the water. On the other hand, when the ulceration is old and the circulation

Inflammation.

through it poor, the aim of the therapeutist is to reawaken the normal reparative process, to bring about increased circulation and increased tissue change, and thereby insure healing. For this reason a blister is placed upon the callous ulcer, which heals with the fresh inflammation thus excited.

The treatment of inflammation of mucous membrane is based upon the same principles as inflammation of the skin, and there too we usually associate means (1) for removing microbes, (2) for destroying them, (3) for lessening the irritation they produce, and (4) for repairing any mischief they have done. Thus in the eye and ear, lotions containing an antiseptic, a sedative, and an astringent are very generally used. For inflammation of the mouth a similar combination is used as a mouth wash, in the throat as a gargle, and in the nose as a wash and sometimes as an ointment or spray, the ointment possessing the advantage of protecting the delicate nasal mucous membrane from irritation by stopping the entrance of irritant dust into the nasal cavities. In the stomach we aid the vomiting by which microbes or the products of decomposition of food are usually eliminated by giving to the patient repeated draughts of hot water so as to wash the stomach clean. Frequently this is sufficient; but if the stomach refuses to eject its objectionable contents, we may either give an emetic or wash it out by means of a stomach-pump or syphon. Similar procedures are used for the intestine, and one of the best methods of treating the diarrhœa consequent upon the presence of irritating substances in the intestinal canal is to give a dose of castor-oil together with a few drops of laudanum. By means of the castor-oil the irritating substances are removed, and the laudanum which is mixed with the purgative soothes the intestine. Even in cases of very acute intestinal diseases similar treatment is now pursued, and instead of treating dysentery simply by sedatives or astringents, an eliminative treatment by means of sulphate of magnesia is largely employed. After the irritant has been removed either from the stomach or intestine, a feeling of irritation of the mucous membrane may remain, and sickness, diarrhœa, or pain may continue in the stomach and intestine although the irritant is no longer present within them, just as the flow of tears and desire to rub may remain in the eye after the piece of grit which has occasioned it may have been removed. The condition which remains after the irritant has been removed is one of inflammation more or less intense. The process of inflammation is a defensive one, but if carried too far may prove injurious.

For the purpose of checking the inflammatory processes and lessening discharge from mucous membranes astringents are employed. Some of these are of mineral and some of vegetable origin, but they almost all possess one chemical property in common, namely, they precipitate albumin. This power is possessed alike by a glass of brandy, by solution of lime, soluble salts of zinc, copper, or silver, by tannic and gallic acids, as well as vegetable juices and extracts which contain them. The strength of the astringent application and the mode of its administration are varied according to the delicacy and position of the mucous membrane affected. Thus to the eye we may use a solution of sulphate of zinc of half a grain to the ounce, while to the ear, urethra, or vagina a solution of four to eight grains or even more may be applied. For the stomach and intestines we employ the same drug in the form of a pill; and when it is desired to act especially upon the intestines, the pills are made of a harder consistence or less soluble preparation, or are covered with keratin, so that they may not act much, if at all, upon the stomach while passing through it before reaching the intestines. The heat which occurs in inflamed parts is chiefly due to the larger amount of blood circulating in the part on account of the dilatation of the vessels. The pain is due to stretching of the nerve fibrils or compression of them by the turgid vessels in the swollen tissues. This latter cause is chiefly observed when the tissues are of a very unyielding character; for example, when the inflammation occurs in a bone or under a thick fibrous and unyielding membrane. The swelling, heat, and pain may sometimes be relieved by mere change of position altering the flow of blood to the inflamed part. Thus when inflammation occurs in the finger, as in a whitlow, the pain is not only constantly severe, but it is increased by every pulsation of the heart, and thus has a throbbing character. By raising the hand nearly to a level with the head both the constant pain and the severity of the throbs may be relieved, as the blood is not sent with such great force into the arteries and returns more readily through the veins. In other parts of the body the same relief may be obtained by raising the inflamed part as high as possible. Relief is frequently given also both by heat and cold, and at first sight it seems strange that agents having such an opposite action should each produce a similar effect. The reason probably is that the application of cold causes contraction of the arteries leading to the inflamed part, while heat by dilating the vessels around forms a side channel through which the blood passes, the tension in the seat of inflammation being thus lessened in both cases. When the inflammation occurs in soft parts where the surrounding vessels can be readily dilated, heat often affords more relief to the pain than cold, but when the inflammation is in a bone or in unyielding fibrous tissues, cold generally gives more relief. For example, the pain of a gum-boil is generally relieved more by warmth, because the yielding tissues of the gum, mouth, and cheek can be readily relaxed by heat and their vessels dilated; but when the pain is dependent upon inflammation in the hard unyielding socket of a tooth, cold generally gives greater relief. The removal of blood, either by incision or by the application of leeches, sometimes gives considerable relief to the pain and tension of inflamed parts. Blisters applied at some distance from inflamed parts are also sometimes useful; and probably they produce this good effect by causing a reflex contraction of the arteries in the inflamed part, and thus acting like a cold application. Certain drugs have the power of relieving inflammation by slowing the heart and rendering its impulse more feeble. Amongst those are to be classed small doses of aconite and colchicum; the former especially tends to lessen the process of inflammation generally, when it is not too severe. There can be little doubt that the intensity of inflammation frequently depends very much on the condition of the blood, and that by altering the blood inflammation may be lessened. Thus free purgation, and especially purgation by cholagogues and salines, has long been recognized as a useful means of reducing the inflammatory process. For example, a mercurial pill at night, followed by salts and senna in the morning, will often relieve the pain in toothache or gum-boil, and lessen inflammation not only in the mouth, but other parts of the body as well. Such remedies are termed *antiphlogistic*. Venesection at one time was highly esteemed as an antiphlogistic measure, and while it is possible that it has now fallen too much into disuse, there can be no doubt that at one time it was very greatly abused, and was carried to such an excess as to kill many patients who would have recovered perfectly had they been let alone. Although the high temperature in an inflamed part is chiefly due to the increased circulation of blood in it, yet the presence of inflammation appears to

cause increased formation of heat either in the inflamed part itself or in the body generally, because we rarely find inflammation exist to any extent without the temperature of the body being raised and a febrile condition produced. (See FEVER.)

Fever.

Two very old remedies for fever are acetate of ammonia and nitrous ether. These were formerly given empirically, simply because they had been found to do good. Now we can see the reason for their administration, because the nitrous ether, consisting chiefly of ethyl nitrite, dilates the superficial vessels and thus allows greater escape of heat from the surface; while acetate of ammonia, by acting as a diaphoretic and stimulating the secretion of sweat, increases the loss of heat by evaporation. When a patient is covered with several blankets, loss of heat from the surface both by radiation and evaporation is to a great extent prevented, but if a cradle be placed over him, so as to raise the bedclothes and allow of free circulation of air around his body, both radiation and evaporation will be increased and the temperature consequently lowered. If his body be left uncovered except by the sheet or blanket thrown over the cradle, the loss of heat is still greater, and it may be much increased by sponging the surface with either hot or cold water so as to leave it slightly moist and increase evaporation. The temperature may be still further reduced by placing vessels filled with ice inside the cradle. When the patient is very restless, so that cradling is impossible, a wet pack may be employed, a sheet wrung out of cold water being wrapped round him, and over this a blanket. The pack has the double effect of restraining his movements and thus lessening the production of heat, while at the same time it dilates the vessels of the skin and produces loss of heat. The restraint which it imposes and the equal distribution of heat over the surface frequently cause sleep quickly in patients who have previously been wildly delirious and entirely sleepless. When the temperature continues to rise in spite of wet sponging and cradling, recourse must be had to the cold bath. The bath should be brought to the bedside and the patient, wrapped in a sheet, should be lifted into it by two attendants. The water should be at the temperature of 90° and gradually reduced by the removal of hot water and displacement by cold, until the temperature of the patient as taken in the mouth is reduced to about 99½° or 99°. After this the patient should be taken out and again put into bed. It is inadvisable to lower the temperature quite to the normal while the patient is in the bath, as frequently it falls after his removal, and may fall so far as to induce collapse. In cases where no bath is available a large mackintosh sheet may be spread upon the bed under the patient, the sides and top may be raised by pillows, and cold water may be applied to the surface of the body with large sponges. The mackintosh sheet forms a shallow bath, and the water may afterwards be run off from it at the lower end of the bed. Another way of applying cold is to dip an ordinary sheet into cold water, apply it for three or four minutes to the surface of the body, then remove it and replace it by another sheet while the first one is being dipped in water. By the alternate use of the two sheets, or by the use of one quickly wrung out of cold water as soon as it becomes warm, the patient's temperature may be rapidly reduced.

There are a number of drugs which have a very powerful action in lowering temperature. Most of these belong to the aromatic group of bodies, although one of them, antipyrin, belongs rather to the furfurol group. Carbolic acid has an antipyretic action, but on account of its poisonous properties it cannot be employed as an antipyretic. Salicylic acid has a strong antipyretic action, and is most commonly used in the form of its sodium salt, which is much more soluble than the acid itself. Amongst other antipyretics, the most important are quinine, phenacetin, and antifebrin. These probably lessen fever by their action upon the nerve centres which regulate the temperature of the body, and partly by their peripheral action in causing the secretion of sweat. Very high fever in itself will cause death, the fatal temperature in rabbits being 114·6°. Before death occurs the pulse and respiration become exceedingly rapid and weak, and complete unconsciousness sets in. That these symptoms are simply due to heat is shown by the fact that if the temperature be quickly reduced by the application of cold the symptoms at once subside. But the delirium which is common in fever, although it may be partly due to rise of temperature, is very often due to poisons in the blood, for in some cases it occurs with quite a low temperature, 101° or 102°, whereas in others the temperature rises to 104° and 105° with no delirium whatever. The presence of toxins in the blood not only affects the brain, causing delirium, but also other organs, the heart and lung, and may cause fatal syncope or respiratory failure.

Anti-toxins and anti-serums.

Many years ago Dr S. L. Mitchell, father of the well-known neurologist, Dr Weir Mitchell, pointed out the close resemblance which exists between symptoms of poisoning by snake venom and infective fevers.[1] Weir Mitchell and others have shown that serpent venom consists chiefly of albumoses, and the toxins formed by infective bacilli have a somewhat similar chemical nature. Calmette and Fraser found that when small doses of snake venom, insufficient to cause death, are injected into an animal, temporary disturbance is produced; but after a few days the animal recovers, and a larger dose is then required to produce any symptoms. By gradually increasing the dose the animal becomes more and more resistant, until at last a dose fifty times as great as that which would at first have produced immediate death can be injected without doing the animal any harm. If a horse be chosen for the experiment, a considerable quantity of blood may be withdrawn without injuring the animal. When this is clotted the serum is found to act as an anti-venin, so that when mixed with the venom of a snake it renders it harmless. Although this result is best obtained when the venom and serum are mixed in a glass before injection, yet if they be injected at the same time in different parts of the body the animal will still be protected and the poison will not produce its usual deadly results. What occurs with snake venom takes place also when the toxins are formed by microbes, and a new method of treatment by anti-toxic serums has been introduced of late years with great success. This is most commonly and successfully used in the treatment of diphtheria. This disease depends upon the presence of a bacillus which grows rapidly at the back of the throat and in the air-passages of children, causing the formation of a membrane which, by plugging the windpipe, causes suffocation and death. At the same time it produces a poison which causes inflammation of the nerves, leading to paralysis, which sometimes proves fatal. By growing this bacillus in broth a toxin is formed which remains in solution and can be separated from the bacilli themselves by filtration. This toxin-containing broth is injected into a horse in increasing doses, just as in the case of the serpent venom, and after the resistance of the horse has been much increased it is bled into sterilized vessels and the blood is allowed to coagulate. The serum is then removed and its anti-toxic power tested by

[1] Quoted by Weir Mitchell, "Researches on the Venom of the Rattlesnake," *Smithsonian Contributions*, 1860, p. 97.

ascertaining the amount necessary to counteract a given amount of active toxin in a guinea-pig of a certain size, the standard weight being three hundred grammes. The serum, the strength of which has thus been ascertained, is distributed in bottles and injected in the proper quantity under the skin of children suffering from diphtheria. If used at an early stage of the disease, and in sufficient quantity, the results are wonderful. The same method of serum therapeutics has been used in other infective diseases, but not with the same success.

Inoculation.

Another therapeutic method which is historically much older than that of serum therapeutics is that of inoculation. The virulence of infective diseases varies in different epidemics, and at different times in the same epidemic. It had been noted that many infective diseases did not attack an individual a second time, the first attack appearing to protect from subsequent ones. The idea of inoculation, therefore, was to infect an individual with a mild form of the disease, so that he should escape infection by a more virulent one. This was tried largely in the case of smallpox, and once at least by Dr Erasmus Darwin in the case of scarlet fever. The worst of this method was that the disease thus inoculated did not always prove of a mild character, and in the case of Dr Erasmus Darwin's son the scarlet fever was exceedingly severe and very nearly proved fatal. To Jenner we owe the discovery that vaccination protects against smallpox, and it is now generally acknowledged that smallpox and vaccine are probably the same disease, the virus of which is modified and its virulence lessened by passing through the body of the cow. Pasteur found that the germs of anthrax could be cultivated outside the body and their virulence weakened either by growing them at too high a temperature or in an unsuitable medium. By inoculating first with a weak virus and then with others which were stronger and stronger, he was able completely to protect oxen either from the effects of inoculation with the strongest virus or from infection through contact with other animals suffering from the disorder. On the other hand, he found the weakened virus could be again strengthened by inoculating a feeble animal such as a guinea-pig a day or two old with it, and then inoculating stronger and stronger animals: an increase in strength was gained with each inoculation, until at last the virus could attack the strongest. A similar increase in virulence appears to occur in plague, where animals, especially rats and mice, seem to be affected before human beings, and not only increase the virulence of the microbes, but convey the infection. Two methods of protective inoculation have been used. In one, Haffkine employs the toxins obtained by growing plague bacilli in broth for five or six weeks, and then heating the whole to 65° or 70° C. so as to destroy the bacilli. This preparation is prophylactic, but does not seem to be curative. Yersin has prepared a serum from horses in the same way as diphtheria anti-toxin, and this is said to have a curative action during the attack. In the same way sterilized cultures of typhoid bacilli have been used to protect against attacks of typhoid fever, and an anti-typhoid serum has been employed with intent to cure. Protection does seem to be afforded, but the curative action of the serum is still somewhat doubtful. Although the anti-toxins which are used in the cure of infective diseases are not dangerous to life, yet they sometimes cause unpleasant consequences, more especially an urticarial eruption almost exactly like that which follows eating mussels or other shell-fish. Sometimes the swelling of the skin is much more general, so that the whole body may be so swollen and puffy as exactly to resemble that of a person suffering from advanced kidney disease. These disagreeable results, however, are not to be compared with the benefits obtained by the injection of anti-toxic serum, and this method of treatment is likely to maintain its place in therapeutics.

Organo-therapeutics.

For many years pepsine has been used as a remedy in dyspepsia to supplement the deficiency of digestive juice in the stomach, and it has been used popularly in dyspepsia for a still longer period. From time immemorial savages have been accustomed to eat the hearts of lions and other wild animals, under the belief that they will thereby obtain courage and strength like that of the animal from which the heart had been taken, but in 1889 Brown-Séquard proposed to use testicular juice as a general tonic and stimulant. Observations were made on the connexion between thyroid gland and myxœdema, which appeared to show that this disease was dependent upon atrophy of the gland. Accordingly the liquid extracts of the gland, or the gland substance itself compressed into tablets, have become largely used in the treatment of the disorder. The success which has been achieved has led to the use of many other organs in a raw or compressed form, or as extracts, in other diseases; *e.g.*, of suprarenal capsule in Addison's disease, of bone marrow in pernicious anæmia, of thymus and suprarenal capsule in exophthalmic goître, of kidney in renal disease, and of pituitary body in acromegaly. To this method of treatment the name of organo-therapeutics has been given. The first scientific attempt to employ portions of raw organs in the treatment of disease was made by Lauder Brunton in diabetes in 1873, sixteen years before Brown-Séquard's paper on the effect of testicular juice. From considering the nature of diabetes, he had come to the conclusion that many cases were due to imperfect oxidation of sugar in the body; that this oxidation was normally carried out by a ferment in the muscles, and that probably the disease was in some cases dependent upon absence of the ferment. He tried to supply this by giving raw meat and glycerine extract of meat, but although he seemed to get some benefit from the treatment, it was not sufficiently marked to attract general attention. His attempts to isolate a glycolytic ferment from flesh were also only partially successful. One of the great difficulties in the way of applying this treatment is that in all probability many of the ferments or enzymes are altered during the process of absorption in the same way as the normal ferments of digestion, and unless the tissue enzymes can be isolated and injected subcutaneously the desired results will not be obtained. The most striking of all the results of organo-therapy are those obtained in myxœdema. In this disease the face is heavy, puffy, and expressionless, the lips thick, the speech slow, the hands shapeless and spade-like, the patient apathetic, the circulation slow, and the extremities cold. Under the influence of thyroid gland these symptoms all disappear, and the patient is frequently restored to a normal condition. When the thyroid gland is absent in children, not only is the expression of the face dull and heavy as in the adult, but the growth both of body and mind is arrested, and the child remains a stunted idiot. The effect of thyroid gland in such cases is marvellous, the child growing in body and becoming healthy and intelligent. In the case of the thyroid the function of the gland appears to be to prepare a secretion which is poured out into the blood and alters tissue-change. When the thyroid tablets or extract of thyroid are given in too large quantities to patients suffering from myxœdema, the symptoms of myxœdema disappear, but in their place appear others indicative of increased metabolism and accelerated circulation.

The pulse-rate becomes very rapid, the extremities become warm, so that the patient is obliged to wear few clothes, the temper becomes irritable, the patient nervous, and a fine tremor is observed in the hands. On stopping the administration of thyroid these symptoms again disappear. When the thyroid is hypertrophied, as in Graves's disease, the same symptoms are observed, and these are probably due to increased secretion from the thyroid. At the same time other symptoms, such as exophthalmos, may appear, which have an independent origin and are not due to the secretion of the gland. The whole of the secretion here is poured into the blood and not at all on to a mucous surface, and herein the thyroid gland differs largely from such glands as the pancreas or peptic and intestinal glands. But it seems now probable that all glands which have what may be termed an external secretion like the pancreas, stomach, intestine, skin, and kidneys have also an internal secretion, so that while they are pouring out one secretion from the ducts into the intestine or external air, they are also pouring into the lymphatics, and thus into the blood, an internal secretion. In fact, a splitting appears to take place in the process of secretion somewhat resembling that which takes place in the formation of a toxin and anti-toxin. The secretion of some digestive glands would prove poisonous if absorbed unchanged. For example, the trypsin of the pancreas (*vide* DIGESTIVE ORGANS) digests albuminous bodies in neutral or alcoholic solution, and if the whole of that which is secreted in the pancreas for the digestion of meat in the intestine were absorbed unchanged into the circulation, it would digest the body itself and quickly cause death. The secretion of trypsin by the pancreas may therefore be looked upon as the formation of a toxin. We do not know at present if any corresponding anti-toxin or anti-trypsin, as we may term it, is returned into the lymphatics or blood from the gland, but the pancreas, which in addition to secreting trypsin secretes a diastatic ferment forming sugar from starch, pours this into the intestine and secretes at the same time a glycolytic ferment which breaks up sugar, and this latter passes into the blood by way of the lymphatics. Thus the gland not only breaks up starch into sugar in the intestine, but breaks up the sugar thus formed after it has been absorbed into the blood. It is by no means improbable that all glands have a double function, and that sometimes the external may be even less important than the internal secretion. On this point, however, we have but little definite knowledge, and a great field is open for future research. At the same time, there are many indications of the importance of an internal secretion in popular treatment. For example, there are many people who feel very much better after profuse perspiration, and as sweat appears to contain little but water and a few salts, it is not improbable that the improvement in their condition is due rather to the internal secretion from the skin than to the elimination effected by the sweat. It is probable that the kidneys also have an internal secretion, and that the great œdema sometimes found in kidney disease (*vide* KIDNEYS) is rather due to the action of some proteid body resembling in its effects the streptococcus anti-toxin, rather than to accumulation of water due to imperfect action of the kidney. Similarly the beneficial effects of purgation may be due not only to the elimination which takes place through the bowel, but also to the internal secretion from the intestinal glands.

The health of the body depends upon the proper kind and supply of food, upon its proper digestion and absorption, on the proper metabolism or tissue-change in the body, and the proper excretion of waste. We have considered how these may be disturbed by microbes from without and from within. We have also considered in a general way the treatment of local diseases by passive protection, active protection, and repair of waste; but both maintenance of health and repair of waste depend very largely upon the condition of the blood. When this is healthy the attacks of microbes are resisted, wounds heal readily, and patients recover from serious diseases which in persons of debilitated constitution would prove fatal. In order to keep the blood in a satisfactory condition it must be well supplied with fresh nutriment, and the products of waste freely eliminated. The food required for the body may be divided into five kinds (*vide* DIETETICS)—carbohydrates, such as starches and sugars; fats; proteids, such as meat and eggs; salts; and last, but not least, water. Water forms almost three-fifths of the weight of the body, so that it amounts to more than all the other constituents put together. Without it life would be impossible, and it is well recognized that death from thirst is more awful than death from hunger. The healthy organism can adapt itself to great varieties both in regard to the quality and quantity of food; but when health begins to fail much care may be required, and many ailments arise from dyspepsia. Imperfect digestion is very often caused by defective teeth or by undue haste in eating, so that the food is bolted instead of being sufficiently masticated and insalivated (*vide* DIGESTIVE ORGANS). The food thus reaches the stomach in large lumps which cannot be readily digested, and either remain there till they decompose and give rise to irritation in the stomach itself, or pass on to the intestine, where digestion is likewise incomplete, and the food is ejected without the proper amount of nourishment having been extracted from it; while at the same time the products of its decomposition may have been absorbed and acted as poisons, giving rise to lassitude, discomfort, headache, or perhaps even to irritability and sleeplessness. Much dyspepsia would be avoided by attention to the condition of the teeth, by artificial teeth when the natural ones are defective, and by obedience to one or two simple rules: (1) to eat slowly; (2) to masticate thoroughly; (3) to take no liquid with meals excepting breakfast, but sip half a pint of hot water on rising in the morning, on going to bed at night, and again about an hour before luncheon and dinner. The object of taking no liquid with meals is that it ensures mastication being more complete, because persons cannot wash the unmasticated food down by drinking, and it prevents the gastric juice from being greatly diluted, and so allows it to digest more rapidly. Should these rules be insufficient, then (4) proteid and farinaceous food should be taken in separate meals—farinaceous food at breakfast, proteid alone at lunch; farinaceous in the afternoon, and proteid again in the evening. The reason for this is that farinaceous foods are digested in the intestine and not in the stomach, where they may undergo fermentation, whereas proteid foods are to a great extent digested in the stomach. When the secretion of gastric juice is deficient it may be excited by gastric tonics, such as ten grains of bicarbonate of soda and a drachm of compound tincture of gentian in water shortly before meals, and may be supplemented by the administration of pepsin and hydrochloric acid after meals. When the nervous system is below par, and both secretion and movements are deficient in the stomach, nervine tonics, such as nux vomica or strychnine, are most useful.

Nutrition and elimination.

High tension in the arteries is often associated with sleeplessness, the pressure of blood being such that the circulation in the brain is constantly maintained at a high

rate of speed and the brain is unable to obtain rest. The means of producing sleep may be divided into two classes: those (1) which lessen the circulation, and which (2) diminish the excitability of the brain cells. The circulation in the brain may be lessened by warmth to the feet, cold to the head, warm food in the stomach, warm poultices or compresses to the abdomen, antipyretics, which reduce the temperature and consequently slow the beats of the heart in fever, and cardiac or vascular tonics, which slow the heart and tend to restore tone to the blood-vessels, so that the circulation in the brain may be more efficiently regulated. Amongst those which lessen excitability of the brain-cells are opium, morphine, hyoscyamus, chloral, sulphonal, trional, paraldehyde, chloralamide, chloralose, hop, and many others. A combination of the two kinds of remedy is sometimes useful, and chloral sometimes succeeds when other things fail, because it depresses the circulation as well as lessens the activity of the brain-cells.

Sleeplessness.

Irritation of sensory nerves tends to cause contraction of the vessels and to raise the blood pressure, and where pain is present opium or morphine is the most efficient sedative. The sensation of pain is felt in the brain, and the cause of it may be in the sensory centres of the brain alone, as in cases of hysterical pain, with no lesion to cause it. Ordinarily, however, it is due to some peripheral irritation which is conducted by sensory nerves to the spinal cord and thence up to the sensory centre in the brain. Pain may be stopped by removing the cause of irritation, as, for example, by the extraction of a carious tooth or by rendering the nerve-endings insensitive to irritation, as by the application of cocaine; by preventing its transmission along the spinal cord by antipyrin, phenacetin, acetanilide, cocaine, &c.; or by dulling the perceptive centre in the brain by means of opium or its alkaloids, by anæsthetics, and probably also, to a certain extent, by antipyrin and its congeners.

Pain.

Deficient nervous action also leads to defective secretion and movement in the intestine, sometimes with flatulent accumulation and sometimes with constipation. In such cases nux vomica or strychnine is useful. Flatulent distension in the stomach or bowels is partly due to air which has been swallowed and partly to gas which has been formed by the decomposition of food. The stomach may become distended with gas on account of acid fermentation leading to the frequent swallowing of saliva, and both this form of flatulence and that caused by the actual formation of gas are much diminished by such drugs as tend to prevent fermentation. Amongst the best of these are carbolic acid in doses of one or two grains, creosote in one or two drops, and sulpho-carbolate of soda in doses of ten grains. Others which may be mentioned are salicylate of bismuth, salol, β-naphthol, and naphthalene. By preventing fermentation in the intestine these also tend to prevent or check diarrhœa, and they may do good after the irritant has been removed by castor oil. After the irritant has been removed and fermentation stopped, the irritation still remaining in the intestinal wall may be soothed by chalk mixture and bismuth, to which if necessary small quantities of opium may be added. In cases where diarrhœa is very obstinate and lasts for weeks, sulphuric acid is sometimes more efficacious than alkalis; and in chronic colics it may be necessary to treat the mucous membrane by local application of astringent solutions. For this purpose solutions of sulphate of copper or of nitrate of silver may be gently introduced into the bowel in quantities of a quart at a time. It is essential that a large quantity should be used, as otherwise the seat of irritation may not be reached by the astringent.

Flatulence.

Constipation is so common that it may be almost looked upon as the normal condition in civilized countries. Two of its chief causes probably are (1) improvement in cookery, whereby the harder and more irritating parts of the food are softened or removed; and (2) improvement in grinding machinery, whereby the harder and more stimulating parts of the grain are separated from the finer flour which is used for bread. In consequence of the absence of mechanical stimulant the bowels act more slowly, and constipation is the result. It may be considerably diminished by a return to a more natural system of feeding, as by using brown bread instead of white, by taking oatmeal porridge, and by eating raw or cooked fruits, such as apples, oranges, prunes, and figs, or preserves made of fruit, such as raspberry and strawberry jam, marmalade, &c., or by vegetables. Should these means fail, aperients may be used. The commonest are senna in the form of compound liquorice powder, sulphur in the form of lozenges, cascara sagrada, either in tablets or in the form of liquid or dry extract, rhubarb, colocynth, and especially aloes. The last acts chiefly upon the lower bowel, and forms a constituent of nearly every purgative pill. The medicines above mentioned may be taken either in a moderate dose at bedtime or in the form of a dinner pill, or they may be taken in small doses three times a day just before or after meals. Some sufferers from constipation find that they get greater relief from salts dissolved in water, or from natural aperient water taken on rising in the morning, and others again find that the best way of opening the bowels is to inject one or two drachms of glycerine into the rectum, or use it as a suppository. If these means fail, exercise, massage, and electricity may help a cure.

Constipation.

The most common diseases of malassimilation are gout, rheumatism, and diabetes. In health most of the nitrogenous waste in the body is eliminated as urea, but in gout uric acid is either formed in too great quantity or too little is eliminated, so that it tends to be deposited as urate of soda in the joints and other tissues. Two means of treating it by diet have been proposed. One is to put the patient on an almost complete vegetarian diet, so as to limit both the amount of uric acid introduced into the body as well as its formation in the body. The other plan is to use an exclusively meat diet, combined with the ingestion of a large quantity of hot water, so as to cause free elimination. Where neither method is strictly pursued it is usual to forbid to gouty patients sugar, pastry, and pickles, and to forbid heavy wines, especially Burgundy and port. During an attack of acute gout nothing relieves so much as colchicum, but during the intervals potash or lithia salts taken in water are advisable, as tending to prevent the deposits of urate of soda. In true diabetes, which probably originates in the central nervous system, as well as in the glycosuria common in gouty patients, sugar in every form should be entirely forbidden, and starchy food restricted to within narrow limits. The remedy most trusted to in this disease is opium and its alkaloids, morphine and codeine. In acute attacks of rheumatism the remedy *par excellence* is salicylate of soda, which reduces the temperature, relieves the pain, and removes the swellings from the joints. Rest in bed should be insisted upon for a longer time than appears actually required, because acute rheumatism tends to bring on cardiac changes, and is more likely to do this when the heart is excited than when the patient is kept at rest. In chronic rheumatism the chief remedies are salicylate of soda, iodide

Diseases of malassimilation.

of potassium, guaiacum, and sulphur, while massage, liniments, and baths are beneficial as local applications.

Elimination of waste-products is one of the most important points in regard to health, and when this is interfered with by disease of the kidneys, the life of the patient is rendered more or less uncertain and the health frequently seriously impaired. In some cases of chronic inflammation of the kidneys, where the disease is not extensive, the patient may continue in fair health for a number of years, provided attention be paid to the following rules:—(1) The body must be kept warm, and chills must be scrupulously avoided; (2) the digestion must be attended to carefully, so that no excess of poisonous bodies is formed in the intestine or absorbed from it; (3) eliminating channels such as the skin and bowel must be kept active. It is usual to reduce the quantity of proteid food to a minimum, in order to lessen the amount of nitrogenous waste to be excreted by the kidneys. Sometimes an entirely milk diet is useful, but in others it does not agree, and a more liberal diet is essential. Alcohol should be avoided as much as possible. The small contracted kidney, which is so common in elderly gouty people, is usually associated with a very large secretion of urine containing only a minute trace of albumin. The tension within the blood-vessels is generally high, and the patients run a risk of anginal attacks or of apoplexy. A nearly vegetarian diet and a complete abstinence from alcoholic stimulants is the ideal in such cases, but it must be modified to suit individuals, as sometimes very strict limitations prove injurious. The daily use of potash, and especially nitrate of potash, tends to reduce the tension and increase the patients' safety, but if pushed too far may sometimes render them very weak and depressed.

Diets and "cures."

It has already been mentioned that water is absolutely necessary for the body: by taking it hot it does not lie like a weight on the stomach, and by taking it an hour before meals it washes out the remnants of the previous meal; and being absorbed into the blood, it probably renders the secretion of gastric juice freer and accelerates digestion, instead of diluting it and interfering with the digestive processes. Where the stomach and bowels are irritable, all food likely to cause mechanical irritation should be avoided, such as skins, bones, fibres, and seeds. In some cases of diarrhœa an entirely milk diet has to be prescribed, and in the diarrhœa of children it is sometimes necessary to alternate a diet of barley water with one of beef juice or white of egg and water, or to give whey instead of milk. The drinking of large quantities of whey is used as a means of cure for dyspepsia in adults, and also in cases of chronic bronchitis. The whey is drunk warm, and for this cure it is usual to go to some Alpine resort where pasturage is abundant and fresh milk can be had at all times of the day. The cure is greatly helped by the fresh air and sunshine of such places, among which are Gais, Heiden, Interlaken, Rorschach, Rigi-Scheideck, and Weggis in Switzerland; Ischl and Meran in Austria; Harzburg, Kreuth, Partenkirchen, Rehburg, Reichenhall, Sankt Blasien, Salzbrunn, and Streitberg in Germany. Another therapeutic method is the so-called "grape cure," in which, along with a regulated diet, five or six pounds of grapes are eaten daily. As the grapes contain a quantity of water and of salts, they tend to lessen the amount of food taken, to increase the action of the bowels, and to stimulate the kidneys. The "grape cure" is used both in chronic disease of the stomach and intestines with or without constipation, and also in cases of gout or ailments depending upon a gouty constitution. The chief places where it is carried on are in the neighbourhood of the Rhine, on the Lake of Geneva, and in the Tirol. Amongst places in the Rhine and its vicinity may be mentioned Cannstadt, Dürkheim, Gleisweiler, Kreuznach, Neustadt, Rüdesheim, St Goar, and Weinheim; on the Lake of Geneva are Montreux and Vevey; and in the Tirol Gries and Meran. The so-called "Salisbury" cure consists of living entirely upon minced beef and hot water. It sometimes answers very well in persons troubled with flatulence, since meat does not give rise to the same amount of gas in the intestines as carbohydrates. During its continuance fat is absorbed from the subcutaneous tissue, and patients become very much thinner, so that it not only lessens flatulence, but reduces obesity. It is, in fact, very much the same system as that proposed a number of years ago by Banting. It is very important for those who are trying this diet to bear in mind the necessity of abundance of water, because sometimes they may be tempted to lessen the water on account of the inconvenience produced either by frequent micturition or too profuse sweats. If the meat diet be continued with too small a proportion of water, a gouty condition may be brought on. This diet has been recommended in gout, and no doubt the essential part of it is the hot water, but there can be little doubt that in fat gouty people it is often useful. An entirely opposite dietary is that in which butcher's meat is completely excluded and proteids reduced to a minimum, as advocated by Dr Haig. This dietary also is very useful in gout, but it answers better in thin gouty people than in fat ones.

The dietaries already mentioned, the whey cure, the grape cure, the meat cure, and the vegetarian cure, are all more or less systems of starvation, one or other article of ordinary diet being either reduced to a minimum or omitted altogether. In three of them at least—the whey cure, the grape cure, and the meat cure—a diminution in one or other of the solid constituents of food is associated with the ingestion of an unusually large quantity of water. In visiting the most famous watering-places, it is curious to note how one finds, in the various waters, here some chloride, there some sulphate, here some potash, there some magnesium, but in all of them we find water. In watching the troops of patients who go to the wells we notice that most of them do more early rising, take more regular exercise, and drink more water in the course of a month at the well than they would do in the rest of the year at home. The watering-places divide themselves, according to the temperature of the waters, into cold and thermal, and according to the composition of the waters, into purgative saline, indifferent saline, sulphur, and iron. Amongst the most celebrated saline waters are those of Carlsbad, which contain sulphate of soda and bicarbonate of soda. These salts crystallize out when the water is partially evaporated and may be used with hot water at home, the best imitation of the Carlsbad water being obtained by mixing with hot water the powdered Carlsbad salts (*pulverförmig*), which contain all the constituents of the natural water. Where it is impossible for the patient to visit Carlsbad, half a teaspoonful or a teaspoonful of salts may be taken in a large tumbler of hot water on rising every morning; but when taken at home the treatment is not so effective as at Carlsbad, because at the wells sipping water is associated with early rising, considerable exercise, and a very carefully regulated diet. It is, indeed, the care with which the diet of patients is regulated and the difficulty that patients find in obtaining forbidden foods at hotels and restaurants, that make Carlsbad better for the liver than any other watering-place. Amongst other places having a similar action are Marienbad, Franzensbad, and Tarasp. The waters just mentioned contain free alkali as well as sulphates, and are employed more

especially in cases of hepatic disorder, such as congestion of the liver, jaundice, gall-stone, and diabetes. A number of other waters containing sulphides and chlorides are powerfully purgative, and are more often drunk at home than at the springs. Amongst these are the Hungarian waters, Æsculap, Apenta, Franz Josef, and Hunyadi Janos; and the Rubinat and Condal waters of Spain. Waters which have a similar composition are drunk at the springs of Leamington and Cheltenham in England, Brides Salins and St Gervais in France, for chronic constipation, dyspepsia, gout, and hepatic disorders of a milder character than those usually treated at Carlsbad. The waters in which chlorides form the purgative principle are those of Homburg, Kissingen, Wiesbaden, and Baden Baden in Germany, and Bridge of Allan in Scotland. Similar waters, but much weaker, are found at Innerleithen and Pitkeithly. Sulphur waters are chiefly used for painful and stiff joints, chronic skin disease, and chronic catarrhal affections. The most important are Aix-les-Bains, and a number of springs in the Pyrenees in France, Aachen in Germany, Harrogate in England, Strathpeffer and Moffat in Scotland. Iron waters are used in anæmia and the affections which are frequently associated with it. The most important are Spa in Belgium, Schwalbach in Germany, St Moritz and Tarasp in Switzerland. Iron waters are, however, common, and are generally found at all those places which have sulphur waters. Simple alkaline waters, containing carbonates, chiefly of sodium along with some magnesium and calcium, are drunk for their utility in gastric and intestinal disorders as well as in rheumatism and gout. They are also employed locally as sprays and douches to the nose, throat, vagina, and rectum, for catarrhal conditions of the mucous membranes. The most important are Vichy and Vals in France and Neuenahr in Germany. Alkaline waters, containing a little common salt, are perhaps even more important than the pure alkaline, as the salt lessens the depressing effect of the alkali. They are therefore used largely in chronic gout, rheumatism, and in calculous affections of the kidney. Amongst the most important are Ems and Wildungen in Germany, Contrexéville and Royat in France.

Simple thermal waters are those which contain only a very small quantity of solids, and owe their efficacy chiefly to their temperature. They are used partly for drinking, but even more so for baths. Bath, Buxton, and Matlock in England; Mallow in Ireland; Wildbad, Schlangenbad, and Badenweiler in Germany; Gastein and Teplitz in Austria; Ragatz and Senkerbad in Switzerland; Plombières and Dax in France; and Bormio in Italy are amongst the best known. When water is dashed against the body with more or less violence, its effects are more powerful than when the body is simply immersed in it. Thus the stimulating effect of sea-bathing is more marked than simple salt-water baths, for in addition to the effect upon the skin produced by the salt and by the temperature of the water, we have the quicker removal of heat by the continual renewal of the water as the waves dash over the body, and mechanical stimulus from its weight and impetus. Somewhat similar effects are produced by so-called wave-baths, and at Nauheim, although the fresh movement of the water against the surface of the body is much less than in the sea, yet its stimulating effect is greatly increased by the presence of carbonic acid in it. Douches have a still more powerful action than waves. They are generally given in the air, but at Plombières very simple douches are given under water. These form a more powerful wave-bath, and are used very successfully for the treatment of abdominal disorders. Douches to the spine are much employed for nervous debility, and good effects are also obtained in such cases from the so-called needle-bath, where small streams of water at high pressure are driven against the whole surface of the body. In the treatment of stiffened joints, massage under water is very serviceable, and in the so-called Aix douche a nozzle from which water continuously streams is fastened to the wrist of the masseur, so that a current of water is constantly playing upon the joint which he is rubbing. While water containing much saline matter, and more especially water containing free carbonic acid, has a very stimulating action upon the skin, mud has a sedative effect, so that in a mud-bath one feels a pleasant soothing sensation as if bathing in cream. These mud-baths are chiefly employed at Marienbad, Franzensbad, and Homburg. Sulphur-baths and sulphur waters are chiefly used in combination for rheumatism and gout, and massage, especially under water, is frequently combined most advantageously with baths and drinking water to effect a cure.

Baths.

Exercises, passive and active, are also used in diseases of the joints, as well as massage and baths, but exercises and training are even more important in cases of cardiac disease. In very bad cases of heart disease, where the patient is unable to go about, the best plan of treatment usually is to make him stay absolutely quiet in bed and have massage, which aids the circulation, tends to remove waste, and increases the appetite. To this is added gentle exercise, beginning with the fingers at first. At Meran walks have been arranged according to Oertel's system, and at Llangammarch in Wales both Oertel's and Schott's systems are employed, and baths according to the Nauheim system are also to be found in London, Sidmouth, Leamington, Buxton, Strathpeffer, &c. Many people who have sedentary employments are unable to get as much exercise as they require because they have not either the time or the opportunity. Such persons may sometimes get a good deal of exercise in a short time by the use of dumb-bells, of elastic cords, or of cords running over pulleys and weighted at one end. The whole system of methodical exercises was started by Ling in Sweden, but it has been developed to a large extent for the purpose of increasing muscular strength by the professional athlete Sandow. Fencing, boxing, wrestling, and the use of a punching-ball may also be resorted to. Walking on the flat is of comparatively little use as a mode of exercise, and has become supplanted to a considerable extent by bicycling. Ascending mountains, however, is very different, because in walking up a steep ascent all the muscles of the body are thrown into action, and not only those of the legs. In addition the purer and rarefied air of the Swiss mountains seems to produce a sense of exhilaration which is not felt nearer the sea-level. For those who suffer from nervous depression, exercise in the Swiss mountains is useful, and even living at a height of about 6000 feet above the sea-level seems to have an exhilarating influence. The nature of this is not very easy to analyse, but as mental depression is closely associated with irritation of the vagus nerve and weakening of the circulation, it seems not at all unlikely that mountain air acts by accelerating the pulse and quickening the circulation, and thus creating a sense of well-being. Indeed, many patients liken its effect to that of drinking champagne. In some persons rarefied air is too stimulating, so that they find difficulty in sleeping, and for those who suffer from insomnia a warm moist air nearer the sea-level is preferable.

Exercise.

It sometimes happens, however, that people cannot sleep at the seaside itself, although they do so perfectly well a mile or two inland. Where the nervous system is exhausted, such warm and moist climates as Malaga, Madeira, Tenerife, and Grand Canary are suitable. In these

places not only is the air moist, but the temperature is particularly equable, and they are therefore suitable places also for persons suffering from kidney disease. Many such persons also do well in dry, warm places, such as the higher reaches of the Nile, Egypt, Mentone, St Raphaël, and other sheltered places on the Riviera. The places mentioned are all suitable for persons suffering from chronic bronchitis, who should avoid any irritation of the larynx, trachea, or bronchi by air which is too dry or which is liable to great changes of temperature. Some cases of phthisis, therefore, do better in warmer and moist climates, and especially those where the larynx has become affected by the disease. Such patients are apt to suffer much from cough and laryngeal irritation in the cold, dry air of the Alps, whereas they live in comparative comfort on the Riviera, in the Canary Islands, Madeira, or at Capri. But warm, moist climates rather favour sedentary habits and tend to lessen appetite, so that the nutrition of the patient is apt to suffer; and although phthisical patients may live in comparative comfort in such climates, their tendency to recovery in them is small. At the Swiss health resorts, on the contrary, during the winter the air is very pure, and has just sufficient coldness to make exercise agreeable to patients. They are thus induced to be out the whole day, and to take food with an appetite which greatly improves their nutrition and aids their restoration to health. The best-known Alpine health resorts are St Moritz and Davos, to which lately Grindelwald has been added. St Moritz is, upon the whole, better for less advanced cases, while Davos is more sheltered and better for cases which are severe. It is a mistake, however, to send those in whom the disease is very far advanced away from home and friends, because when there is no hope of cure it is better for them to die in comfort at home. At the health resorts just mentioned the amount of food taken is regulated by the appetite of the patient himself, but a system of cure has been inaugurated by Dr Brehmer at Görbersdorf, by Dr Dettweiler at Falkenstein, and by Dr Walther at Nordrach, in the Black Forest. The most important point in this treatment consists in forced feeding, the want of appetite which is so prominent in many cases of phthisis being regarded as an abnormal sensation not to be regarded; and under the forced feeding, combined with open-air life, many marvellous recoveries are recorded. Numerous other institutions have been started in imitation of Dr Walther's, but their success or failure must depend very much on the doctor who directs them. In the well-known "rest" cure, which we owe to Weir Mitchell, forced feeding takes a prominent part. The essence of this cure is to give to the patient rest, bodily and mental, by confinement to bed and isolation from the outside world. While this treatment by itself would aid recovery from nervous exhaustion, it would lessen appetite and thus interfere with nervous repair; but the want of exertion is supplied by means of massage, which stimulates the circulation and increases the appetite, so that the patient gets all the benefit of exercise without any exhaustion. Where nervous exhaustion is less marked and the Weir Mitchell treatment is not appropriate—for example, in men who are simply overworked or broken down by anxiety or sorrow—a sea voyage is often a satisfactory form of "rest" cure. The lack of posts and telegrams prevents much of the excitement which they would have upon shore, the space for exercise is limited, food is abundant and appetite is supplied by the stimulus of constant exposure in the open air. In order that the voyage should be satisfactory, however, it must be sufficiently long, and the weather must be sufficiently warm to allow the patient to stay in the open air the whole day long. During the heat of summer voyages to the North Cape are suitable, and during the spring and autumn to the Mediterranean, but in the colder months of the year the West Indies, India, Cape Town, Australia, or New Zealand forms the best objective. (T. L. B.)

Health resorts.

Theresienstadt (Czech, *Terezin*), a royal free town and important garrison in the government district of Leitmeritz, Bohemia, Austria, situated on the Eger river, near its confluence with the Elbe, in a district known as the "Bohemian Paradise," from its wealth of fruit trees. The fortress erected here by the Empress Maria Theresa in 1780 was abandoned in 1882; but the place remains one of considerable strategic importance, owing to its position on both banks of the Eger in the midst of a broad plain. It lies on the border between the Czech and German portions of Bohemia, and its inhabitants belong to both nationalities. The basaltic cones of the Mittelgebirge are visible from the town. Population (1890), 7215; (1900), 7046, including garrison of 3998 men.

Therezina, a town of Brazil, and capital of the state of Piauhy. It was formerly called Chapada do Corisco, and has several fine churches and public buildings. Among the manufacturing industries are a large factory for making cotton and thread, an iron foundry, a soap factory, and machines for assorting and pressing cotton. Population, 22,000.

Thermochemistry. — Thermochemistry is a branch of Energetics, and treats of the thermal phenomena which are associated with chemical change.

§ 1. That vigorous chemical action is accompanied by a brisk evolution of heat is evident from such familiar examples as the combustion of fuel or the explosion of gunpowder. The heat attendant on these actions, and on the vital processes of the animal organism, naturally first attracted attention. Boyle, Crawford, Lavoisier and Laplace, Dulong, Davy, Rumford, all concerned themselves with thermochemical investigations of such processes. Their quantitative experiments were, however, too rough to permit of accurate generalization; and although Lavoisier and Laplace stated the principle that the same amount of heat must be supplied to decompose a compound as would be produced on its formation, the statement was not based on exact experiment, and only received experimental confirmation much later.

The beginnings of modern thermochemistry, though made independently of the doctrine of the Conservation of Energy, are practically contemporaneous with the recognition of that law, and without it the science could scarcely have reached the degree of development which it rapidly attained. Thomas Andrews and, especially, G. H. Hess (1840) were the first who systematically investigated thermochemical effects in solution, and arrived at conclusions from their experimental data which still possess validity. Andrews, for example, found that when a series of acids were under similar conditions used to neutralize a given amount of a base, the quantity of heat evolved on the neutralization was the same in all cases. Hess, from his work, arrived at the converse conclusion, that when a series of bases were used to neutralize a given amount of an acid, the heat of neutralization was always the same. Both of these statements are correct when the powerful mineral acid and bases are considered, exceptions only arising when weak acids and bases are employed. Again, Andrews discovered that when one metal displaces another from solution of its salts (*e.g.*, zinc with solutions of copper salts), the thermal effect is practically independent of the nature of the acid radical in the salt employed. Andrews

likewise found that when the heat evolved on the displacement from its salts of a metal M′ by a metal M is added to the heat of displacement of another metal M″ by M′, the sum is equal to the heat which is evolved on the direct displacement of M″ from its salts by M. This affords an example of a principle which had been stated by Hess in a very general form under the name of the *Law of Constant Heat Sums*—namely, that the thermal effect of a given chemical action is the same, independently of the character and number of the stages in which it takes place. Thus, in the above example, it is immaterial whether M displaces M″ from its salt directly, or whether M first displaces M′, which is then used to displace M″. This important principle is a direct consequence of the Law of the Conservation of Energy, but was discovered independently by Hess from accurate experiment.

Hess employed this principle to determine indirectly the *heat of formation* of compounds from their elements, when this magnitude, as is generally the case, was inaccessible to direct measurement. Thus the heat of formation of anhydrous zinc sulphate, $ZnSO_4$, which cannot be determined directly, may be arrived at by summation (in Hess's units) as follows :—

Oxidation of Zn to ZnO	5291	units
,, S ,, SO_3	6384	,,
Dissolution of SO_3 in much water	2566	,,
,, ZnO in the resulting aqueous H_2SO_4	1609	,,
	15850	,,
Deduct heat of dissolution of anhydrous $ZnSO_4$	1193	,,
Heat of formation of $ZnSO_4$ from Zn, S, and 4O =	14657	,,

Heats of formation are still determined for the most part in a precisely similar manner.

Hess also stated another principle on empirical grounds, which, although admitting of many exceptions, is of considerable utility and significance. It had been known long before his time that when solutions of neutral salts were mixed, and no precipitate resulted, the mixed solution was also neutral. Hess now observed that in the process of mixing such neutral solutions no thermal effect was produced—that is, neutral salts in aqueous solution could apparently interchange their radicals without evolution or absorption of heat. These experimental results were generalized by him under the title of the *Law of Thermoneutrality*.

After the investigations of Hess and Andrews, a great deal of excellent experimental work was performed by Favre and Silbermann, whose chief theoretical achievement was the recognition that the heat of neutralization of acids and bases was additively composed of two constants, one determined by the acid and the other by the base. This deduction harmonized the observations of Andrews and of Hess previously alluded to, and also accounted satisfactorily for the Law of Thermoneutrality.

The Danish chemist, Julius Thomsen (born 1826), was the first investigator who deliberately adopted the principle of the Conservation of Energy as the basis of a thermochemical system. His thermochemical work was begun in 1853, but most of his experiments were performed in the years 1869–82, the whole being published collectively, under the title *Thermochemische Untersuchungen*, in four volumes. Somewhat later than Thomsen, the distinguished French chemist, Marcellin Berthelot, began (in 1873) a series of thermochemical determinations, which by the hands of himself and his pupils have been continued to the present day (1902). It is to these two investigators that most of our exact thermochemical data are due.

Thomsen and Berthelot independently enunciated a generalization (commonly known as Berthelot's *Third Principle*, or *Principle of Maximum Work*), which may be stated in brief as follows :—Every pure chemical reaction is accompanied by *evolution* of heat. Whilst this principle is undoubtedly applicable to the great majority of chemical actions under ordinary conditions, it is subject to numerous exceptions, and cannot therefore be taken (as its authors originally intended) as a secure basis for theoretical reasoning on the connexion between thermal effect and chemical affinity. The existence of reactions which are reversible on slight alteration of conditions at once invalidates the principle, for if the action proceeding in one direction evolves heat, it must absorb heat when proceeding in the reverse direction. As the principle has now been abandoned even by its authors, it is at the present time only of historical importance, although for many years it exerted considerable influence on thermochemical research.

§ 2. From the standpoint of the Law of the Conservation of Energy, the relation between chemical and thermochemical action bears the following aspect :—A given amount of any substance under given conditions possesses a perfectly definite amount of intrinsic energy, and, no matter what chemical and physical transformations the substance may undergo, it will, when it returns to its original state, possess the original amount of intrinsic energy. If we consider now the transformation of one system of chemical substances into another system under specified conditions, we shall find that in general the intrinsic energy of the second system is different from the intrinsic energy of the first. Let us assume, as is commonly the case, that the intrinsic energy of the initial system is greater than that of the final system. When the first system then is transformed into the second, the excess of energy which the former possesses must appear in the shape of heat, light, electrical energy, mechanical energy, &c. It is for the most part a simple matter to obtain the excess of energy entirely in the form of heat, the amount of which is easily susceptible of measurement, and thus the existence of thermochemistry as a practical science is rendered possible. Since the intrinsic energies of the two systems under given conditions are invariable, the difference between them is constant, so that the heat evolved when the first system is converted into the second is equal to that absorbed when the second system is retransformed into the first (cf. Lavoisier and Laplace, *ante*, § 1). The total thermal effect too, which is associated with the transformation, must be the same, whether the transformation is conducted directly or indirectly (Hess's *Law of Constant Heat Sums*), since the thermal effect depends only on the intrinsic energies of the initial and final systems.

Since the intrinsic energy of a substance varies with the conditions under which the substance exists, it is necessary, before proceeding to the practical application of any of the laws mentioned above, accurately to specify the conditions of the initial and final systems, or at least to secure that they shall not vary in the operations considered. It is also a necessary condition for the application of the preceding laws that no form of energy except heat and the intrinsic energy of the substances should be ultimately involved. For example, when metallic zinc is dissolved in dilute sulphuric acid with production of zinc sulphate (in solution) and hydrogen gas, a definite quantity of heat is produced for a given amount of zinc dissolved, provided that the excess of energy in the initial system appears entirely as heat. This provision may not always be fulfilled, since by placing the zinc in electrical contact with a piece of platinum, likewise immersed in the sulphuric acid, we can generate a current of electricity

through the solution and the metallic part of the circuit. The reaction as before is completely expressed by the chemical equation

$$Zn + H_2SO_4 = ZnSO_4 + H_2,$$

the initial and final systems being exactly the same as in the first case; yet the amount of heat generated by the action is much smaller, a quantity of the intrinsic energy having been converted into electrical energy. This electrical energy, however, is equivalent to the heat which has disappeared, for it has been shown experimentally that if it is converted into heat and added to the heat actually evolved, the total quantity of heat obtained is exactly equal to that produced by the direct dissolution of the zinc in the absence of platinum.

§ 3. The following conditions have to be considered as affecting in a greater or less degree the intrinsic energy of the initial and final systems:—

(1) Dilution of solutions.
(2) Physical state.
(3) Change of volume.
(4) Allotropic modifications.
(5) Temperature.

(1) Generally speaking, there is a considerable thermal effect when a substance is dissolved in water, and this effect varies in magnitude according to the amount of water employed. It is only, however, when we deal with comparatively concentrated solutions that the heat-effect of diluting the solutions is at all great, the heat-change on diluting an already dilute solution being for most practical purposes negligible. In dealing, therefore, with dilute solutions, it is only necessary to state that the solutions are dilute, the exact degree of dilution being unimportant. It occasionally happens that a change in dilution affects the chemical action that occurs. Thus if concentrated instead of dilute sulphuric acid acts upon zinc, the action takes place to a great extent not according to the equation given above, but according to the equation

$$Zn + 2H_2SO_4 = ZnSO_4 + SO_2 + 2H_2O,$$

sulphur dioxide and water being produced instead of hydrogen. Here we have a different final system with a different amount of intrinsic energy, so that the thermal effect of the action is altogether different.

(2) The physical state of the reacting substances must be considered, since comparatively large amounts of heat are absorbed on fusion and on vaporization. Thus the heat of fusion of ice (for $H_2O = 18$ g) is 1440 cal., and the heat of vaporization of water at 100°, for the same quantity, 9670 cal.

(3) The effect of change of volume against external pressure (due to production or consumption of mechanical energy) may be neglected in the case of solids, liquids, or solutions, but must usually be taken into account when gases are dealt with. Each gramme-molecule of a gas which appears under constant pressure during a chemical action (*e.g.*, hydrogen during the action of zinc on dilute sulphuric acid) performs work equivalent to 580 cal. at the ordinary temperature, which must be allowed for in the thermochemical calculation. A similar correction, of opposite sign, must be made when a gramme-molecule of gas disappears during the chemical action.

(4) When a substance—*e.g.*, carbon, phosphorus, sulphur—exists in more than one allotropic modification, the particular variety employed should always be stated, as the conversion of one modification into another is frequently attended by a considerable thermal effect. Thus the conversion of yellow into red phosphorus evolves about one-sixth of the heat of combustion of the latter in oxygen, and so the knowledge of which variety of phosphorus has been employed is of essential importance in the thermochemistry of that element.

(5) The influence of temperature on the thermal effect of a chemical action is sometimes considerable, but since the initial and final temperatures, which alone determine the variation in the thermal effect, are in almost all cases within the ordinary laboratory range of a few degrees, this influence may in general be neglected without serious error.

§ 4. *Methods.*—In order to estimate the thermal effect of any chemical process, use is made of the ordinary methods of calorimetry, the particular method being selected according to the nature of the chemical action involved. In almost every case the method of mixture (CALORIMETRY, *Ency. Brit.*, vol. xxvi. p. 505) is employed, the method of fusion with Bunsen's ice-calorimeter (*ibid.*) being only used in special and rarely occurring circumstances.

As a very great number of important chemical actions take place on mixing solutions, the method for such cases has been thoroughly studied. When the solutions employed are dilute, no water is placed in the calorimeter, the temperature-change of the solutions themselves being used to estimate the thermal effect brought about by mixing them. Known quantities of the solutions are taken, and the temperature of each is accurately measured before mixing, the solutions having been allowed as far as possible to adjust themselves to the same temperature. The change of temperature of the solutions after the mixing has taken place is then observed with the usual precautions. It is of course in such a case necessary to know the specific heat of the liquid in the calorimeter. Thomsen by direct experiment found that the heat-capacity of a dilute aqueous solution diverged in general less than 1 per cent. from the heat-capacity of the water contained in it, the divergence being sometimes in one sense, sometimes in the other. He therefore abstained from determining for each case the specific heats of the solutions he employed, and contented himself with the above approximation. Berthelot, on the other hand, assumed that the heat-capacity of an aqueous solution is equal to that of an equal volume of water, and calculated his results on this assumption, which involves much the same uncertainty as that of Thomsen. Since thermochemical measurements of this type may be frequently performed with an error due to other causes of much less than 1 per cent., the error introduced by either of these assumptions is the chief cause of uncertainty in the method.

The calorimeter used for solutions is usually cylindrical, and made of glass or a metal which is not attacked by the reacting substances. The total quantity of liquid employed need not in general exceed half a litre if a sufficiently delicate thermometer is available. The same type of calorimeter is used in determining the heat of solution of a solid or liquid in water.

Combustion calorimeters are employed for observing the heat generated by the brisk interaction of substances, one of which at least is gaseous. They are of two kinds. In the older type the combustion chamber (of metal or glass) is sunk in the calorimeter proper, tubes being provided for the entrance and exit of the gaseous substances involved in the action. These tubes are generally in the form of worms immersed in the water of the calorimeter. In the newer type (which was first proposed by Andrews for the combustion of gases) the chemical action takes place in a completely closed combustion chamber of sufficient strength to resist the pressure generated by the sudden action, which is often of explosive violence. The steel combustion chamber is of about 250 c.c. capacity,

and is wholly immersed in the calorimeter. To withstand the chemical action of the gases, the "calorimetric bomb" is lined either with platinum, as in Berthelot's apparatus, or with porcelain, as in Mahler's. For ordinary combustions compressed oxygen is used, so that the combustible substance burns almost instantaneously, the action being induced by means of some electrical device which can be controlled from without the calorimeter. The accuracy of heats of combustion determined in the closed calorimeter is in favourable cases about one-half per cent. of the quantity estimated.

§ 5. *Units and Notation.*—The heat-units employed in thermochemistry have varied from time to time. The following are those which have been in most general use :—

Small calorie or gramme calorie	cal.
Large or kilogramme calorie	Cal.
Centuple or "rational" calorie	K.

The centuple calorie is the amount of heat required to raise 1 g. of water from 0° C. to 100° C., and is approximately equal to 100 cal. The large calorie is equal to 1000 cal. In view of the not very great accuracy of thermochemical measurements, the precise definition of the heat-unit employed is not a matter of special importance. It has lately been proposed to adopt the *joule*, with the symbol j, as thermochemical unit for small quantities of heat, large amounts being expressed in terms of the *kilojoule*, Kj = 1000 j. (For the exact relation between these heat-units, see CALORIMETRY, vol. xxvi. p. 509.) For ordinary thermochemical work we may adopt the relation 1 cal. = 4·18 j, or 1 Cal. = 4·18 Kj.

Except for technological purposes, thermochemical data are not referred to unit quantity of matter, but to chemical quantities—*i.e.*, to the gramme-equivalents or gramme-molecules of the reacting substances, or to some multiples of them. The notation which Julius Thomsen employed to express his thermochemical measurements is still extensively used at the present day, and is as follows :—The chemical symbols of the reacting substances are written in juxtaposition and separated by commas; the whole is then enclosed in brackets and connected by the sign of equality to the number expressing the thermal effect of the action. The chemical symbols stand for quantities measured in grammes, and heat-evolution is reckoned as positive, heat-absorption as negative. Thus

$$[S, 2O] = 71100 \text{ cal.}$$

indicates that 71100 calories are evolved when 32 grammes of sulphur react with 2×16 grammes of free oxygen to form sulphur dioxide. It is of course necessary in accurate work to state the conditions of the reaction. In the above instance the sulphur is supposed to be in the solid rhombic modification, the oxygen and sulphur dioxide being in the gaseous state, and the initial and final systems being at the ordinary temperature. Again, the equation

$$[2N, O] = -18500 \text{ cal.}$$

indicates that if 28 grammes of nitrogen could be made to unite directly with 16 grammes of oxygen to form nitrous oxide, the union would cause the absorption of 18500 calories. When substances in solution are dealt with, Thomsen indicates their state by affixing Aq to their symbols. Thus

$$[NaOH\ Aq, HNO_3\ Aq] = 13680 \text{ cal.}$$

represents the heat of neutralization of one gramme-equivalent of caustic soda with nitric acid, each in dilute aqueous solution before being brought into contact. One drawback of Thomsen's notation is that the nature of the final system is not indicated, although this defect in general causes no ambiguity.

Berthelot's notation defines both initial and final systems by giving the chemical equation for the reaction considered, the thermal effect being appended, and the state of the various substances being affixed to their formulæ after brackets. Ostwald has proposed a modification of Berthelot's method which has many advantages, and is now commonly in use. Like Berthelot, he writes the chemical equation of the reaction, but in addition he considers the chemical formula of each substance to express not only its material composition, but also the (unknown) value of its intrinsic energy. To the right-hand member of the equation he then adds the number expressing the thermal effect of the reaction, heat-evolution being as before counted positive, and heat-absorption negative. The mass-equation then becomes an energy equation. He thus writes

$$S + O_2 = SO_2 + 71100 \text{ cal.},$$

which expresses the fact that the intrinsic energy of the quantities of sulphur and oxygen considered exceeds that of the sulphur dioxide derived from them by 71100 cal. when thermal units are employed. The equation

$$H_2 + I_2 = 2HI - 12200 \text{ cal.}$$

expresses that under certain conditions the intrinsic energy of hydriodic acid is greater than the intrinsic energy of its component elements by 12200 cal., *i.e.*, that hydriodic acid is formed from its elements with absorption of this amount of heat. Energy equations, such as the above, may be operated with precisely as if they were algebraic equations, a property which is of great advantage in calculation. Thus by transposition we may write the last equation as follows :—

$$2HI = H_2 + I_2 + 12200 \text{ cal.},$$

and thus express that hydriodic acid when decomposed into its elements evolves 12200 cal. for the quantity indicated by the equation.

Ostwald has made the further proposal that the formulæ of solids should be printed in heavy type (or within square brackets), of liquids in ordinary type, and of gases in italics (or within curved brackets), so that the physical state of the substances might be indicated by the equation itself. Thus the equation

$$Cl_2 + 2KI,\ Aq = 2KCl,\ Aq + I_2 + 52400 \text{ cal.},$$

or

$$(Cl_2) + 2KI,\ Aq = 2KCl,\ Aq + [I_2] + 52400 \text{ cal.},$$

would express that when gaseous chlorine acts on a solution of potassium iodide, with separation of solid iodine, 52400 calories are evolved. These suggestions have not as yet been widely adopted.

§ 6. *Heat of Formation.*—For thermochemical calculations it is of great importance to know the heat of formation of compounds from their elements, even when the combination cannot be brought about directly. As an example of the use of Ostwald's energy-equations for the indirect determination we may take the case of carbon monoxide.

The following equations give the result of direct experiment :—

$$C + 2O = CO_2 + 94300 \text{ cal.}$$
$$CO + O = CO_2 + 68000 \text{ cal.}$$

If now it is required to find the heat of formation of the compound CO, which cannot be directly ascertained, we have merely to subtract the second equation from the first, each symbol representing constant intrinsic energy, and thus we obtain

$$C + O - CO = 26300 \text{ cal.},$$

or

$$C + O = CO + 26300 \text{ cal.},$$

that is, the heat of formation of a gramme-molecule of carbon monoxide is 26300 cal.

As has already been stated, the heat of formation of a compound is the amount (expressed in thermal units) by which its intrinsic energy exceeds or falls short of that of the elements which enter into its composition. Now of the absolute values of intrinsic energy we know nothing; we can only estimate differences of intrinsic energy when one system is compared with another into which it may be directly or indirectly converted. But since the elements cannot under any circumstances be converted one into the other, we are absolutely without knowledge of the relative values of their intrinsic energy. This being the case, we are at liberty to make the assumption that the intrinsic energy of each element (under specified conditions) is zero, without thereby introducing any risk of self-contradiction in thermochemical calculations. This assumption has the great advantage, that the intrinsic energy of a compound relatively to its elements now appears as the heat of formation of the compound with its sign reversed. Thus if we consider the energy equation

$$C + O_2 = CO_2 + 94300 \text{ cal.},$$

and replace the symbols by the values of the intrinsic energy, viz., zero for carbon and oxygen, and x for carbon dioxide, we obtain the equation

$$0 + 0 = x + 94300 \text{ cal.}$$

or

$$x = -94300 \text{ cal.}$$

With knowledge then of the heats of formation of the substances involved in any chemical action, we can at once calculate the thermal effect of the action, by placing for each compound in the energy-equation its heat of formation with the sign reversed, *i.e.*, its heat of decomposition into its elements. Thus if we wish to ascertain the thermal effect of the action

$$Mg + CaO = MgO + Ca,$$

we may write, knowing the heats of formation of CaO and MgO to be 131000 and 146000 respectively,

$$0 - 131000 = 0 - 146000 + x$$

$$x = 15000 \text{ cal.}$$

Since heats of formation afford such convenient data for calculation on the above method, they have been ascertained for as many compounds as possible.

Substances with positive heats of formation are termed *exothermic;* those with negative heats of formation are termed *endothermic.* The latter, which are not very numerous, give out heat on decomposition into their elements, and are more or less unstable. Amongst endothermic compounds may be noted hydriodic acid, HI, acetylene, C_2H_2, nitrous oxide, N_2O, nitric oxide, NO, azoimide, N_3H, nitrogen trichloride, NCl_3. Some of these pass into their elements with explosive violence, owing to the heat generated by their decomposition and the gaseous nature of the products.

§ 7. *Heat of Combustion.*—The thermochemical magnitude which is universally determined for organic compounds is the heat of combustion, usually by means of the calorimetric bomb. The relation between the heat of combustion of a hydrocarbon and its heat of formation may be readily seen from the following example. The hydrocarbon methane, CH_4, when completely burned to carbon dioxide and water, generates 213800 cal. We may therefore write

$$CH_4 + 4O = CO_2 + 2H_2O + 213800.$$

Now we know the heats of formation of carbon dioxide (from diamond) and of liquid water to be 94300 cal. and 68300 cal. respectively. The above equation may consequently be written, if x is the heat of formation of methane,

$$-x + 0 = -94300 - (2 \times 68300) + 213,800$$

$$x = 17000 \text{ cal.}$$

This heat of formation, like that of most hydrocarbons, is comparatively small: the heat of formation of saturated hydrocarbons is always positive, but the heat of formation of unsaturated hydrocarbons is frequently negative. For example, ethylene, C_2H_4, is formed with absorption of 16200 cal., acetylene, C_2H_2, with absorption of 59100 cal., and liquid benzene, C_6H_6, with absorption of 9100 cal. Since the heat of combustion of a hydrocarbon is equal to the heat of combustion of the carbon and hydrogen it contains minus its heat of formation, those hydrocarbons with positive heat of formation generate less heat on burning than the elements from which they were formed, whilst those with a negative heat of formation generate more. Thus the heat generated by the combustion of acetylene, C_2H_2, is 316000 cal., whereas the heat of combustion of the carbon and hydrogen composing it is only 256900 cal., the difference being equal to the negative heat of formation of the acetylene.

For substances consisting of carbon, hydrogen, and oxygen, a rule was early devised for the purpose of roughly calculating their heat of combustion (Welter's rule). The oxygen contained in the compound was deducted, together with the equivalent amount of hydrogen, and the heat of combustion of the compound was then taken to be equal to the heats of combustion of the elements in the residue. That the rule is not very accurate may be seen from the following example. Cane-sugar has the formula $C_{12}H_{22}O_{11}$. According to Welter's rule, we deduct 11 O with the equivalent amount of hydrogen, namely, 22 H, and are left with the residue 12 C, the heat of combustion of which is 1131600 cal. The observed heat of combustion of sugar is, however, 1354000, so that the error of the rule is here 20 per cent. A much better approximation to the heat of combustion of such substances is obtained by deducting the oxygen together with the amount of carbon necessary to form CO_2, and then ascertaining the amount of heat produced by the residual carbon and hydrogen. In the above case we should deduct with 11 O the equivalent amount of carbon 5·5 C, thus obtaining the residue 6·5 C and 22 H. These when burnt would yield $(6{\cdot}5 \times 94300) + (11 \times 68300) = 1364250$ cal., an amount which is less than 1 per cent. different from the observed heat of combustion of sugar. Neither of the above rules can be applied to carbon compounds containing nitrogen.

§ 8. *Heat of Neutralization.*—It has already been stated that the heats of neutralization of acids and bases in aqueous solution are additively composed of two terms, one being constant for a given base, the other constant for a given acid. In addition to this, the further regularity has been observed that when the powerful monobasic acids are neutralized by the powerful monacid bases, the heat of neutralization is in all cases the same. The following table gives the heats of neutralization of the commoner strong monobasic acids with soda:—

Hydrochloric acid .	HCl . . .	137400 cal.
Hydrobromic acid .	HBr . . .	137500 ,,
Hydriodic acid .	HI . . .	136800 ,,
Nitric acid . .	HNO_3 . .	136800 ,,
Chloric acid . .	$HClO_3$ . .	137600 ,,
Bromic acid . .	$HBrO_3$ . .	137800 ,,

Within the error of experiment these numbers are identical.

It was at one time thought that the greater the heat of neutralization of an acid with a given base, the greater was the strength of the acid. It is now known, however, that when weak acids or bases are used, the heat of neutralization may be either greater or less than the normal value for powerful acids and bases, so that there is no proportionality, or even parallelism,

between the strengths of acids and their heats of neutralization.

§ 9. *Heat of Solution.*—When substances readily combine with water to form hydrates, the heat of solution in water is usually positive; when, on the other hand, they do not readily form hydrates, or when they are already hydrated, the heat of solution is usually negative. The following examples show the effect of hydration on heat of solution in a large quantity of water :—

	Heat of Solution.	Heat of Hydration.
I. Sodium carbonate—		
Na_2CO_3 . .	+5640 cal.	...
Na_2CO_3, H_2O .	+2250 ,,	+3390 cal.
Na_2CO_3, $2H_2O$.	+20 ,,	+5620 ,,
Na_2CO_3, $10H_2O$.	-16160 ,,	+21800 ,,
II. Sodium sulphate—		
Na_2SO_4 . .	+460 cal.	. .
Na_2SO_4, H_2O .	-1900 ,,	+2360 cal.
Na_2SO_4, $10H_2O$.	-18760 ,,	+19200 ,,

§ 10. *Application of the Second Law of Thermodynamics to Thermochemistry.* — What is commonly understood by thermochemistry is based entirely on the first law of thermodynamics, but of recent years great progress has been made in the study of chemical equilibrium by the application of the second law. For an account of work in this direction the reader may consult the last two books given in the short bibliography subjoined.

See JULIUS THOMSEN. *Thermochemische Untersuchungen.* Leipzig, 1882–86.—M. (J. WAL.)

Thermodynamics. — The name Thermodynamics is given to that branch of the general science of Energetics which deals with the relations between thermal and mechanical energy, and the transformations of heat into work, and *vice versâ*. Other transformations of heat (see ENERGETICS) are often included under the same title, but they cannot be considered here. A discussion of some of the fundamental principles and equations of thermodynamics has been given under the same title in *Ency. Brit.* vol. xxiii., p. 283. The object of the present article is to explain more fully the applications of the theory to imperfect gases and vapours under conditions which occur in practice, and to develop certain equations which are interesting in themselves and are required for reference in cognate subjects. (See THERMOMETRY, FUSION, VAPORIZATION.) An alphabetical index of the symbols employed will be found at the end of the article.

1. *Introductory.*—The modern science of thermodynamics dates from about the year 1850, in which Rankine and Clausius independently and simultaneously published the correct interpretation of Carnot's principle on the basis of the law of the conservation of energy, which had already won general acceptance through the work of Joule and Thomson and of Helmholtz. It was in the same year that Joule's principal paper on the mechanical equivalent of heat was published in the *Philosophical Transactions*. About the same time Thomson devised the absolute or thermodynamic scale of temperature, without which no scientific treatment of the subject was possible, and developed the fundamental equations of the subject in the most general manner. The previous work of Carnot and others had been founded on the assumption that heat, like a material substance, possessed the property of remaining invariable in quantity through any transformation. Carnot, in the proof of his principle that the efficiency of a reversible heat engine is a maximum, assumed that the case of a heat engine receiving a quantity of heat, H', from a source at a temperature, θ', and giving up a quantity of heat, H'', to a sink at a lower temperature, θ'', was exactly analogous to that of a water engine taking water from a high level and letting it down to a lower level. In the latter case, the maximum work that could be done by any kind of water-wheel would be equal to the product of the difference of level and the weight of water transferred. This maximum output could be attained only by a perfectly reversible water-wheel, capable, if driven backwards, of restoring the water to its original level by the expenditure of a like amount of work. For if there were any more efficient engine, A, capable of doing more work with the same quantity of water and the same difference of level, it would be possible to obtain a balance of work without any expenditure of water power by employing A to drive a reversible engine backwards and return the water to its original level. On Carnot's assumption with regard to the indestructibility of heat, it follows by exactly similar reasoning that the efficiency W/H (the ratio of work done, W, to heat transferred, H) of a perfectly reversible heat engine is the maximum attainable, and cannot be exceeded by any other engine working between the same limits of temperature. The fallacy of Carnot's proof became evident when it was admitted that heat was a form of energy, and therefore capable of transformation. The adoption of the principle of the conservation of energy in place of that of the conservation of heat made it necessary to suppose (as was experimentally proved by Hirn and others at a later date) that part of the heat, H', taken from the source was transformed into work and disappeared, ceasing to exist as heat. The quantity of heat, H'', given up to the sink was therefore less than H'. The simple proof given by Carnot on the basis of the conservation of heat no longer held good, and it became necessary to devise some other axiom on which to found the proof of Carnot's principle. Either of the axioms chosen for this purpose by Clausius and Thomson (Lord Kelvin) may be stated as the second law of thermodynamics, but as they are equivalent to Carnot's principle, and may be deduced from it, it is more convenient in practice to take Carnot's principle itself as the second law.

2. *Application of the First Law.*—The complete transformation of mechanical energy into heat by friction, or some analogous process of degradation, is always possible, and is made the basis of experiments for the determination of the mechanical equivalent of the heat unit. (See CALORIMETRY.) The converse process of the transformation of heat into mechanical work or other forms of energy is subject to limitations. When a quantity of heat, H, is supplied to a body, part is expended in raising the temperature of the body, or in expanding the volume against molecular forces, and is represented by an increase in the total quantity of energy contained in the body, which is generally called its *Intrinsic Energy*, and will be denoted by the symbol E. The remainder is equivalent to the external work, W, done *by* the body in expanding or otherwise, which can be utilized for mechanical purposes, and ceases to exist as heat in the body. The application of the first law leads immediately to the equation,

$$H = E - E_0 + W, \quad . \quad . \quad . \quad (1)$$

in which E_0 represents the quantity of energy originally present in the body, and all the quantities are supposed, as usual, to be expressed in mechanical units. This equation is generally true for any series of transformations, provided that we regard H and W as representing the *algebraic sums* of all the quantities of heat supplied to, and

of work done *by* the body, heat taken *from* the body or work done *on* the body being reckoned negative in the summation. $E - E_0$, then, represents the total increase of the intrinsic energy of the body in its final state, which may be determined by measuring H and W. If after any series or cycle of transformations the body is restored to its initial state, we must have $E = E_0$, whence it follows that $H = W$. But this simple relation is only true of the net balances of heat and work in a complete cyclical process, which must be adopted for theoretical purposes if we wish to eliminate the unknown changes of intrinsic energy. The balance of work obtainable in such a cycle depends on the limits of temperature in a manner which forms the subject of the second law.

3. *Indicator or p.v. Diagram.*—The significance of relation (1) is best appreciated by considering the graphic representation of quantities of heat and energy on a work-diagram. On the familiar indicator diagram the state of the working substance is represented by the position of a point called the "state-point," defined by the values of the pressure p and volume v of *unit mass*, as ordinate and abscissa respectively (Fig. 1). Any line ("path" or "graph") on the diagram, such as BCD, represents an "operation" or "process," *i.e.*, a continuous series of states through which the substance may be made to pass in any transformation. It is tacitly assumed that the motion is relatively so slow that the pressure and temperature of the substance are practically uniform throughout its mass at any stage of the process. Otherwise the transformation could not be fully represented on the diagram, and would not be reversible. The area BCD$d\flat$ under the path represents the external work done *by* the substance in expanding from B to D, which is analytically represented by the integral of pdv taken along the given path. Any closed path or figure, such as ABCD, represents a complete cycle or series of operations, in the course of which the substance is restored to its original state with respect to temperature, intrinsic energy, and other properties. The area DAB$\flat d$ under the return path (v diminishing) represents work done *on* the substance, or against the back-pressure, and is negative. The area of the cycle, viz., that enclosed by the path BCDA, represents the balance of external work done by the substance in one cycle, and is positive if the cycle is described clockwise as indicated by the arrows. The simplest types of process or operation are:—(1), heating or cooling *at constant volume*, represented by vertical lines such as B$\flat$, called *Isometrics*, in which the pressure varies, but no external work is done. (2) Heating or cooling *at constant pressure*, represented by horizontal lines such as NA, called *Isopiestics*, in which the external work done is the product of the pressure p and the expansion $v'' - v'$. (3) Expansion or compression *at constant temperature*, represented by curves called *Isothermals*, such as BC, AD, the form of which depends on the nature of the working substance. The isothermals are approximately equilateral hyperbolas (pv = constant), with the axes of p and v for asymptotes, for a gas or unsaturated vapour, but coincide with the isopiestics for a saturated vapour in presence of its liquid. (4) Expansion or compression under the condition of *heat-insulation*, represented by curves called *Adiabatics*, such as BAZ or CDZ′, which are necessarily steeper than the isothermals.

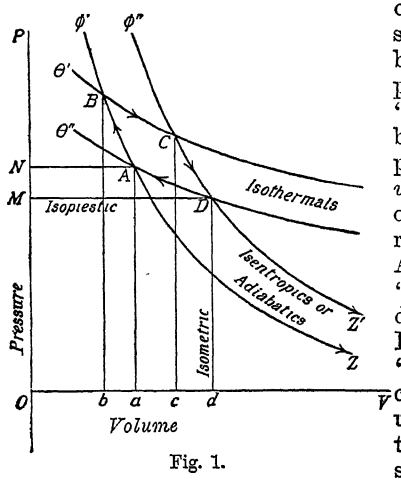

Fig. 1.

A cycle such as ABCD enclosed by parts of two isothermals, BC, AD, and two adiabatics, AB, CD, is the simplest form of cycle for theoretical purposes, since all the heat absorbed, H', is taken in during the process represented by one isothermal at the temperature θ', and all the heat rejected, H'', is given out during the process represented by the other at the temperature θ''. This is the cycle employed by Carnot for the establishment of his fundamental principle of reversibility as the criterion of perfect efficiency in a heat engine. The area ABCD, representing the work, W, per cycle, is the difference $(H' - H'')$ of the quantities of heat absorbed and rejected at the temperatures θ' and θ''. As the temperature θ'' is lowered, the area of the cycle increases, but since W can never exceed H', there must be a zero limit of temperature at which the pressure would vanish and the area of the cycle become equal to the whole heat absorbed at the higher temperature. Taking this ideal limit as a theoretical or absolute zero, the value of H' may be represented on the diagram by the whole area included between the two adiabatics BAZ, CDZ′ down to the points where they intersect the isothermal of absolute zero, or the zero isopiestic OV asymptotically at infinity.

If the substance in any state such as B were allowed to expand adiabatically ($dH = 0$) down to the absolute zero, at which point it contains no heat and exerts no pressure, the whole of its intrinsic heat energy might theoretically be recovered in the form of external work, represented on the diagram by the whole area BAZc$\flat$ under the adiabatic through the state-point B, bounded by the isometric B$\flat$ and the zero isopiestic $\flat$V. The change of the intrinsic energy in passing from one state to another, as from B to C, is represented by the addition of the heat-area H = BCZZ′, and the subtraction of the work-area W = BCc$\flat$. It follows from the first law that the intrinsic energy of a substance in a given state must always be the same, or that the change of E in any transformation must depend only on the initial and final states, and not on the path or process. It will be observed that the areas representing H and W both depend on the form of the path BC, but that the difference of the areas representing the change of intrinsic energy dE is independent of BC, which is a boundary common to both H and W. This is mathematically expressed by the statement that dE is an exact differential of a function of the co-ordinates defining the state of the body, which can be integrated between limits without reference to the relation representing the path along which the variations are taken.

4. *Application of the Second Law.*—The limitations of the transformation of heat into work in a cyclical process, such as is necessarily involved in the working of any form of heat engine, form the subject of the second law, and are most conveniently stated in terms of the absolute scale of temperature devised by Lord Kelvin on the basis of Carnot's principle. Since the efficiency of all perfectly reversible engines working between the same two limits of temperature in a cycle of the kind illustrated in Fig. 1 must be the same, it follows that it can depend only on the limits of temperature, and not on the mechanism of the engine, or on the nature of the working substance employed. Any scale of temperature defined in terms of the ratios of the quantities of heat absorbed and rejected by a reversible engine will be *absolute* in the sense of being independent of the properties of any particular substance. The scale proposed by Lord Kelvin, and now

universally adopted, is obtained by taking the ratio θ'/θ'' of the temperatures of the source and the sink to be the same as the ratio H'/H'' of the quantities of heat absorbed and rejected at those temperatures in a simple Carnot cycle. Since $H'-H''=W$, we thus obtain the simple relations,

$$W/(\theta'-\theta'')=H'/\theta'=H''/\theta'' \quad . \quad (2)$$

The scale of temperature so defined leads to the simplest thermodynamical relations, and has the great advantage of being in the closest possible agreement with the scales of the mercury and gas-thermometers. The size of the degree of temperature is determined by the system of graduation employed (Centigrade, or Fahrenheit, or Réaumur) with reference to the freezing and boiling points of water, but this does not affect the ratios involved in (2), and is immaterial for theoretical purposes. Having due regard to the meaning of the symbols employed, the relations (2) may also be interpreted as the formula of the simple reversible engine, or as the symbolic statement of Carnot's principle, since the assertion that the efficiency depends only on the temperature limits is implicitly involved in the form of the equations.

5. *Thermodynamical Relations.*—The most important and most useful of the relations between the thermodynamical properties of a substance may be very simply deduced from a consideration of the indicator diagram by a geometrical method, which is in many respects more instructive than the analytical method generally employed. Referring to Fig. 2, let BC be a small portion of any isothermal corresponding to the temperature θ', and AD a neighbouring isothermal θ''. Let BE be an isometric through B meeting AD in E, and EC an isopiestic through E meeting BC in C. Let BA, CD be adiabatics through B and C meeting the isothermal θ'' in A and D. Then by relations (2) the heat, H, absorbed in the isothermal change BC, is to the work, W, done in the cycle ABCD in the ratio of θ' to $(\theta'-\theta'')$. If the difference of temperature $(\theta'-\theta'')$ is small, the figure ABCD may be regarded as a parallelogram, and its area W as equal to the rectangle BE × EC. This is accurately true in the limit when $(\theta'-\theta'')$ is infinitesimal, but in practice it is necessary to measure specific heats, &c., over finite ranges of temperature, and the error involved is generally negligible if the range does not exceed a few degrees. BE is the increase of pressure $(p'-p'')$ produced by the rise of temperature $(\theta'-\theta'')$ if the volume is kept constant. EC is the expansion $(v''-v')$ produced by the same rise of temperature if the pressure is kept constant. Substituting these symbols in the expression for the area, the relation becomes

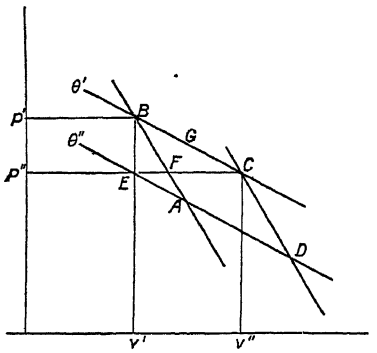

Fig. 2.

$$H=\theta(p'-p'')(v''-v')/(\theta'-\theta'') \quad . \quad . \quad . \quad (3)$$

This relation may be interpreted in two ways, according as we require the heat absorbed in terms of the change of pressure or volume. (1) The heat, H, absorbed in isothermal expansion (latent heat of expansion) from p' to p'' is equal to the diminution of pressure $(p'-p'')$ multiplied by the absolute temperature and by the expansion per degree $(v''-v')/(\theta'-\theta'')$ at constant pressure. (2) The heat, H, absorbed in isothermal expansion from v' to v'' is equal to the increase of volume $(v''-v')$ multiplied by the absolute temperature, and by the increase of pressure per degree $(p'-p'')/(\theta'-\theta'')$, at constant volume. In the notation of the calculus the relations become

$$\left.\begin{aligned} -dH/dp\ (\theta\ \text{const})&=\theta dv/d\theta\ (p\ \text{const})\\ dH/dv\ (\theta\ \text{const})&=\theta dp/d\theta\ (v\ \text{const})\end{aligned}\right\} \quad . \quad . \quad (4)$$

The negative sign is prefixed to dH/dp because absorption of heat $+dH$ corresponds to diminution of pressure $-dp$. The utility of these relations results from the circumstance that the pressure and expansion coefficients are familiar and easily measured, whereas the latent heat of expansion is difficult to determine.

The most instructive example of the application of relations (1) and (2) is afforded by the change of state of a substance at constant temperature and pressure. Starting with unit mass of the substance in the first state (*e.g.*, liquid) possessing volume v' at a temperature θ'' and pressure p'' represented by the point A in Fig. 3, the heat absorbed in raising the temperature to θ' and the pressure to p' without change of state may be written $s'(\theta'-\theta'')$, where s' is the specific heat of the substance in the first state at saturation pressure.

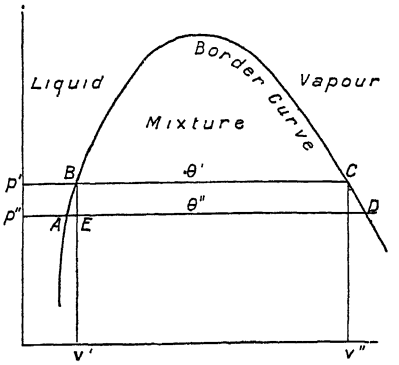

Fig. 3.

If now the substance in the state B is entirely converted at constant temperature and pressure into the second state (*e.g.*, saturated vapour), in which it occupies a volume v'', the line BC represents the change of volume $(v''-v')$. The heat absorbed in this change is called the latent heat of change of state, and may be represented by the symbol L'. The substance is then cooled to the lower temperature θ'' along the path CD, keeping it in the saturated state. The heat evolved in this process may be represented by $s''(\theta'-\theta'')$, where s'' is the specific heat of the substance in the second state at saturation pressure. Finally, the substance is reconverted into the first state at the temperature θ'', completing the cycle by the abstraction of a quantity of heat L''. By the application of the first law, the difference of the quantities of heat absorbed and evolved in the cycle must be equal to the work represented by the area of the cycle, which is equal to $(p'-p'')(v''-v')$ in the limit when the difference of pressure is small. By the application of the second law, relations (2), the same work area is equal to $(\theta'-\theta'')L'/\theta'$. Dividing by $(\theta'-\theta'')$, and writing $dp/d\theta$ and $dL/d\theta$ for the limiting values of the ratios $(p'-p'')/(\theta'-\theta'')$ and $(L'-L'')/(\theta'-\theta'')$, we obtain the important relations

$$s'-s''+dL/d\theta=(v''-v')dp/d\theta=L/\theta, \quad . \quad . \quad . \quad (5)$$

in which $dp/d\theta$ is the rate of change of pressure with temperature when the two states are in equilibrium, and not necessarily at constant volume, as in the previous example.

6. *Ratio and Difference of Specific Heats.*—If we take unit mass of the substance at B, Fig. 2, and cool it at constant volume to E, through an interval of temperature $(\theta'-\theta'')$, the amount of heat abstracted may be written $h=s(\theta'-\theta'')$, where s is the specific heat *at constant volume*. If, starting from E, *the same* amount of heat h is restored *at constant pressure*, we should arrive at the point F on the adiabatic through B, since the substance has been transformed from B to F by a reversible path without loss or gain of heat on the whole. In order to restore the substance to its original temperature θ' *at constant pressure*, it would be necessary to supply a further quantity of heat, H, represented by the area between the two adiabatics from FC down to the absolute zero. This quantity of heat is the same as that already found in equation (3), but for the small area BFC, which is negligibly small in the limit compared with H. The whole quantity of heat required to raise the temperature from θ'' to θ' at constant pressure along the path EC is $H+h$, which is equal to $S(\theta'-\theta'')$, where S is the specific heat at constant pressure. Since $h=s(\theta'-\theta'')$, the difference $S-s$ between the specific heats at constant pressure and volume is evidently $H/(\theta'-\theta'')$. Substituting for H its value from (3), and employing the notation of the calculus, we obtain the relation

$$S-s=\theta(dp/d\theta)(dv/d\theta), \quad . \quad . \quad . \quad . \quad (6)$$

in which the partial differential coefficients have the same meaning as in (4).

Since the amounts of heat supplied at constant pressure from E to F and from E to C are in the limit proportional to the expansions EF and EC which they produce, the ratio S/s is equal to the ratio EC/EF. EF is the change of volume corresponding to a change of pressure BE when no heat is allowed to escape and the path is the adiabatic BF. EC is the change of volume for *the same* change of pressure BE when the path is the isothermal BC. These changes of volume are directly as the compressibilities, or inversely as the elasticities. If we write K for the adiabatic elasticity, and k for the isothermal elasticity, we obtain

$$S/s=\text{EC}/\text{EF}=K/k \quad . \quad . \quad . \quad . \quad (7)$$

The value of the specific heat S at constant pressure can always be determined by experiment, and in practice is one of the most important thermodynamical properties of a substance. The value of the specific heat s at constant volume can also be

measured in a few cases, but it is generally necessary to deduce it from that at constant pressure by means of relation (6). It is often impossible to observe the pressure-coefficient $dp/d\theta$ directly, but it may be deduced from the isothermal compressibility by means of the geometrically obvious relation, $BE=(BE/EC)\times EC$. The ratio BE/EC of the diminution of pressure to the increase of volume at constant temperature; or $-dp/dv$, is readily observed.

The amount of heat absorbed in any small change of state, as from E to G in Fig. 2, may be found by adding to the heat required for the change of temperature at constant volume, $sd\theta$, or at constant pressure, $Sd\theta$, the heat absorbed in isothermal expansion as given by relations (4). We thus obtain the expressions

$$dH=sd\theta+\theta(dp/d\theta)dv=Sd\theta-\theta(dv/d\theta)dp \quad . \quad . \quad (8)$$

The first is equivalent to measuring the heat along the path EBG, the second along the path ECG. The two differ by the area BEC, which can be neglected if the change is small. For a finite change it is necessary to represent the path by a series of small steps, which is the graphic equivalent of integration along the path represented by the given relation between v and θ, or p and θ. If we put $dH=0$ in equations (8), we obtain the relations between dv and $d\theta$, or dp and $d\theta$, under the condition of no heat-supply, *i.e.*, along the adiabatic, which can be integrated, giving the equations to the adiabatics, provided that the values of the specific heats and expansion-coefficients are known.

6. *Intrinsic Energy.*—The change of intrinsic energy E along any path is found by subtracting the work pdv from either of the expressions for dH. Since the change of energy is independent of the path, the finite change between any two given states may be found by integration along *any* convenient path. It is generally convenient to divide the path into two steps, isothermal and isometric, or isothermal and isopiestic, and to integrate along each separately. The change of energy at constant volume is simply $sd\theta$, the change at constant temperature is $(\theta dp/d\theta-p)dv$, which may be written

$$dE/d\theta\ (v\ \text{const})=s,\ dE/dv\ (\theta\ \text{const})=\theta dp/d\theta-p \quad . \quad . \quad (9)$$

These must be expressed as functions of v and θ, which is theoretically possible if the values of s, p, and $dp/d\theta$ are known. Since the two expressions (9) are the partial differential-coefficients of a single function E of the independent variables v and θ, we shall obtain the same result, namely $d^2E/d\theta dv$, if we differentiate the first with respect to v and the second with respect to θ. We thus obtain the relation

$$ds/dv(\theta\ \text{const})=\theta d^2p/d\theta^2\ (v\ \text{const}), \quad . \quad . \quad . \quad (10)$$

which is useful for calculating the variation of the specific heat s with variation of density at constant temperature. A similar expression for the variation of the specific heat S at constant pressure is obtained from the second expression in (8), by taking p and θ as independent variables; but it follows more directly from a consideration of the variation of the function $(E+pv)$.

7. *Total Heat.*—The function $F=(E+pv)$, like E itself, has a value depending only on the state of the body. It may conveniently be called the *Total Heat*, by a slight extension of the meaning of a term which has been for a long time in use as applied to vapours (see VAPORIZATION). Since $dE=dH-pdv$, we have evidently for the variation of the total heat from the second expression (8),

$$dF=d(E+pv)=dH+vdp=Sd\theta-(\theta dv/d\theta-v)dp \quad . \quad (11)$$

This expression shows that the rate of variation of the total heat with temperature at constant pressure is equal to the specific heat at constant pressure. To find the total heat of a substance in any given state defined by the values of p and θ, starting from any convenient zero of temperature, it is sufficient to measure the total heat required to raise the substance to the final temperature under a constant pressure equal to p. For instance, in the boiler of a steam engine the feed water is pumped into the boiler against the final pressure of the steam, and is heated under this constant pressure up to the temperature of the steam. The total heat with which we are actually concerned in the working of a steam engine is the total heat as here defined, and not the total heat as defined by Regnault, which, however, differs from $(E+pv)$ only by a quantity which is inappreciable in ordinary practice.

Observing that F is a function of the co-ordinates expressing the state of the substance, we obtain for the variation of S with pressure at constant temperature

$$dS/dp\ (\theta\ \text{const})=d^2F/d\theta dp=-\theta d^2v/d\theta^2\ (p\ \text{const}) \quad . \quad (12)$$

If the heat supplied to a substance which is expanding reversibly and doing external work, pdv, is equal to the external work done, the intrinsic energy, E, remains constant. The lines of constant energy on the diagram are called *Isenergics*. The equation to these lines in terms of v and θ is obtained by integrating

$$dE=sd\theta+(\theta dp/d\theta-p)dv=0 \quad . \quad . \quad . \quad (13)$$

If, on the other hand, the heat supplied is equal to $-vdp$, we see from (11) that F remains constant. The equation to the lines of constant total heat is found in terms of p and θ by putting $dF=0$ and integrating (11).

8. *Ideal Gases.*—The simplest and most instructive illustration of the foregoing principles is afforded by a consideration of the properties of an ideal gas, and of the manner in which actual gases deviate from the ideal state. According to the elementary kinetic theory, an ideal monatomic gas is imagined to consist of a number of very small and perfectly elastic particles, each of mass m, moving in all directions with a velocity u, depending on the temperature. In the state of equilibrium of a mixture of different gases the mean kinetic energy $mu^2/2$ of each kind of molecule must be the same. This mean kinetic energy is the natural measure of the temperature, since the energy is assumed to be wholly kinetic, and equal increments of heat produce equal increments of energy. The specific heat at constant volume is constant and equal to $u^2/2\theta$. The pressure p due to the molecular impacts is $u^2/3v$. We thus obtain the ideal characteristic equation

$$pv=R\theta/M=u^2/3=2s\theta/3, \quad . \quad . \quad . \quad . \quad (14)$$

in which R is a constant, the same for all ideal gases, and M is the molecular weight relative to the standard for which the value of R is calculated. It is assumed in establishing these relations that the molecules themselves are so small that the space which they occupy is a negligible fraction of that occupied by the gas, and that the duration of an intermolecular collision may be neglected in comparison with the time between two consecutive encounters of the same molecule with another. It is also assumed that there are no forces of attraction or repulsion between molecules, so that no work is done against molecular forces in change of volume. The change of energy in isothermal expansion is zero, and the heat absorbed is equal to the external work. This assumption gives $\theta dp/d\theta=p$, by relations (4), which are equivalent to (2). But by (14) $\theta dp/d\theta=p$, hence the scale of temperature given by the ideal gas coincides with the scale defined by (2). The difference of the specific heats, $(S-s)=R/M$, and the ratio S/s is constant, being equal to 5/3 for a monatomic gas. The adiabatic elasticity is Sp/s, and the adiabatic equation $pv^{S/s}=$ constant.

9. *Deviations of Actual Gases from the Ideal State.*—Since no gas is ideally perfect, it is more important for practical purposes to discuss the deviations of actual gases from the ideal state, and to consider how their properties may be thermodynamically explained and defined. The most natural method of procedure is to observe the deviations from Boyle's law by measuring the changes of pv at various constant temperatures. But this procedure in itself is not sufficient, because, although it would be highly probable that a gas obeying Boyle's law at all temperatures was practically an ideal gas, it is evident that Boyle's law would be satisfied by any substance having the characteristic equation $pv=f(\theta)$, where $f(\theta)$ is any arbitrary function of θ, and that the scale of temperatures given by such a substance would not necessarily coincide with the absolute scale. An ideal gas is often defined as one which obeys the law of Boyle, and also that of Charles. But the latter does not afford a practical test, as the gas thermometer itself is the only available standard for measuring temperature. A sufficient test, in addition to Boyle's law, is the condition $dE/dv=0$ at constant temperature, which is assumed in the elementary kinetic theory. This gives by equation (9) the condition $\theta dp/d\theta=p$, which is satisfied by any substance possessing the characteristic equation $p/\theta=f(v)$, where $f(v)$ is any arbitrary function of v. In order that a substance of this nature may also satisfy Boyle's law, it is necessary that its characteristic equation should be that of the ideal gas. In that case its specific heat must be constant, and its temperature scale must coincide with the absolute scale. This test was applied by Joule in the well-known experiment in which he allowed a gas to expand from one vessel to another in a calorimeter without doing external work. Under this condition the increase of intrinsic energy would be equal to the heat absorbed, and would be indicated by fall of temperature of the calorimeter. Joule failed to observe any change of temperature in his apparatus, and was therefore justified in assuming that the increase of intrinsic energy of a gas in isothermal expansion was very small, and that the absorption of heat observed in a similar experiment in which the gas was allowed to do external work by expanding against the atmospheric pressure was equivalent to the external work done. But owing to the large thermal capacity of his calorimeter, the test, though sufficient for his immediate purpose, was not delicate enough to detect and measure the small deviations which actually exist.

10. *Method of Joule and Thomson.*—William Thomson (Lord Kelvin), who was the first to realize the importance of the absolute scale in thermodynamics, and the inadequacy of the test afforded by Boyle's law or by experiments on the constancy of the specific

heat of gases, devised a more delicate and practical test, which he carried out successfully in conjunction with Joule. A continuous stream of gas, supplied at a constant pressure and temperature, is forced through a porous plug, from which it issues at a lower pressure through an orifice carefully surrounded with non-conducting material, where its temperature is measured. If we consider any short length of the stream bounded by two imaginary cross-sections A and B, unit mass of the fluid in passing A has work, $p'v'$, done on it by the fluid behind and carries its energy, $E'+U'$, with it into the space AB, where U' is the kinetic energy of flow. In passing B it does work, $p''v''$, on the fluid in front, and carries its energy, $E''+U''$, with it out of the space AB. If there is no external loss or gain of heat through the walls of the pipe, and if the flow is steady, so that energy is not accumulating in the space AB, we must evidently have the condition $E'+U'+p'v'=E''+U''+p''v''$ at any two cross-sections of the stream. It is easy to arrange the experiment so that U is small and nearly constant. In this case the condition of flow is simply that of constant total heat, or in symbols, $d(E+pv)=0$. We have therefore, by equation (11),

$$Sd\theta=(\theta dv/d\theta-v)dp, \quad . \quad . \quad . \quad (15)$$

where $d\theta$ is the fall of temperature of the fluid corresponding to a diminution of pressure dp. If there is no fall of temperature in passing the plug, $d\theta=0$, and we have the condition $\theta dv/d\theta=v$. The characteristic equation of the fluid must then be of the form $v/\theta=f(p)$, where $f(p)$ is any arbitrary function of p. If the fluid is a gas also obeying Boyle's law, $pv=f(\theta)$, then it must be an ideal gas. As the result of their experiments on actual gases (air, hydrogen, and CO_2), Joule and Thomson (*Phil. Trans.* 1854, 1862) found that the cooling effect, $d\theta$, was of the same order of magnitude as the deviations from Boyle's law in each case, and that it was proportional to the difference of pressure, dp, so that $d\theta/dp$ was nearly constant for each gas over a range of pressure of five or six atmospheres. By experiments at different temperatures between 0° and 100° C., they found that the cooling effect per atmosphere of pressure varied inversely as the square of the absolute temperature for air and CO_2. Putting $d\theta/dp=A/\theta^2$ in equation (15), and integrating on the assumption that the small variations of S could be neglected over the range of the experiment, they found a solution of the type, $v/\theta=f(p)-SA/3\theta^3$, in which $f(p)$ is an arbitrary function of p. Assuming that the gas should approximate indefinitely to the ideal state $pv=R\theta$ at high temperatures, they put $f(p)=R/p$, which gives a characteristic equation of the form

$$v=R\theta/p-SA/3\theta^2. \quad . \quad . \quad . \quad (16)$$

An equation of a similar form had previously been employed by Rankine (*Trans. Roy. Soc. Ed.* 1854) to represent Regnault's experiments on the deviations of CO_2 from Boyle's law. This equation is practically identical for moderate pressures with that devised by Clausius (*Phil. Mag.* 1880) to represent the behaviour of CO_2 up to the critical point. Experiments by Natanson on CO_2 at 17° C. confirm those of Joule and Thomson, but show a slight increase of the ratio $d\theta/dp$ at higher pressures, which is otherwise rendered probable by the form of the isothermals as determined by Andrews and Amagat. More recent experiments by Grindley (*Proc. Roy. Soc.* 1899) and Callendar (*Proc. Roy. Soc.* 1900) on steam confirm this type of equation, but give much larger values of the cooling effect than for CO_2, and a more rapid rate of variation with temperature.

11. *Modified Joule–Thomson Equation.*—Hirn (*Théorie Mec. de la Chaleur*, ii. p. 211, Paris, 1869) proposed an equation of the form $(p+p_0)(v-b)=R\theta$, in which the effect of the size of the molecules is represented by subtracting a quantity b, the "covolume," from the volume occupied by the gas, and the effect of the mutual attractions of the molecules is represented by adding a quantity p_0, the internal pressure, to the external pressure, p. This type of equation was more fully worked out by van der Waals, who identified the internal pressure, p_0, with the capillary pressure of Laplace, and assumed that it varied directly as the square of the density, and could be written a/v^2. This assumption represents qualitatively the theoretical isothermal of James Thomson (see VAPORIZATION) and the phenomena of the critical state (see CONDENSATION OF GASES); but the numerical results to which it leads differ so widely from experiment that it is necessary to suppose the constant, a, to be a function of the temperature. Many complicated expressions have been suggested by subsequent writers in the attempt to represent the continuity of the gaseous and liquid states in a single formula, but these are of a highly empirical nature, and beyond the scope of the present inquiry. The simplest assumption which suffices to express the small deviations of gases and vapours from the ideal state *at moderate pressures* is that the coefficient a in the expression for the capillary pressure varies inversely as some power of the absolute temperature. Neglecting small terms of the second order, the equation may then be written in the form

$$v-b=R\theta/p-c_0(\theta_0/\theta)^n=V-c, \quad . \quad . \quad (17)$$

in which c is a small quantity (expressing the defect from the ideal volume $V=R\theta/p$ due to co-aggregation of the molecules) which varies inversely as the nth power of θ, but is independent of p to a first approximation at moderate pressures. The constant c_0 is the value of c at some standard temperature θ_0. The value of the index, n, appears to be different for different types of molecule. For CO_2 at ordinary temperatures $n=2$, as in the Joule–Thomson equation. For steam between 100° and 150° C. it approaches the value 3·5. It is probably less than 2 for air and the more perfect gases. The introduction of the covolume, b, into the equation is required in order to enable it to represent the behaviour of hydrogen and other gases at high temperatures and pressures according to the experiments of Amagat. It is generally taken as constant, but its value at moderate pressures is difficult to determine. According to van der Waals, assuming spherical molecules, it should be four times; according to O. E. Meyer, on slightly different assumptions, it should be $4\sqrt{2}$ times, the actual volume of the molecules. It appears to be a quantity of the same order as the volume of the liquid, or as the limiting volume of the gas at very high pressures. The value of the co-aggregation volume, c, at any temperature, assuming equation (17), may be found by observing the deviations from Boyle's law and by experiments on the Joule–Thomson effect. Differentiating equation (17) at constant pressure to find $dv/d\theta$, and observing that $dc/d\theta=-nc/\theta$, we find by substitution in (15) the following simple expression for the cooling effect $d\theta/dp$ in terms of c and b,

$$Sd\theta/dp=(n+1)c-b \quad . \quad . \quad . \quad (18)$$

Experiments at two temperatures suffice to determine both c and n if we assume that b is equal to the volume of the liquid. But it is better to apply the Boyle's law test in addition, provided that errors due to surface condensation can be avoided. The advantage of this type of equation is that c is a function of the temperature only. Other favourite types of equation for approximate work are (1) $p=R\theta/v+f(v)$, which makes p a linear function of θ at constant volume, as in van der Waals's equation; (2) $v=R\theta/p+f(p)$, which makes v a linear function of θ at constant pressure. These have their advantages in special cases as empirical formulæ (*e.g.*, Zeuner's formula for steam), but they cannot be made to represent with sufficient approximation the deviations from the ideal state at moderate pressures. In the modified Joule–Thomson equation (17), both c and n have simple theoretical interpretations, and it is possible to express the thermodynamical properties of the substance in terms of them by means of reasonably simple formulæ.

12. *Application of the Modified Equation.*—We may take equation (17) as a practical example of the thermodynamical principles already given. The values of the partial differential coefficients in terms of n and c are as follows—

$$dv/d\theta\ (p\ \text{const})=(R/p)(1+nc/V) \quad . \quad . \quad (19)$$
$$d^2v/d\theta^2 \quad ,, \quad =-n(n+1)c/\theta^2 \quad . \quad . \quad (20)$$
$$dp/d\theta\ (v\ \text{const})=(R/V)(1+nc/V) \quad . \quad . \quad (21)$$
$$d^2p/d\theta^2 \quad ,, \quad =Rnc(1-n+2nc/V)/\theta V^2 \quad . \quad (22)$$
$$-dp/dv\ (\theta\ \text{const})=p/V. \quad . \quad . \quad . \quad . \quad (23)$$

Substituting these values in equations already given, we find,

from (6) $S-s=R(1+nc/V)^2$ . . . (24)
,, (9) $dE/dv\ (\theta\ \text{const})=ncp/V$ . . . . (25)
,, (11) dF/dp ,, $=(n+1)c-b$ . . . (26)
,, (10) ds/dv ,, $=(1-n+2nc/V)Rnc/V^2$. (27)
,, (12) dS/dp ,, $=n(n+1)c/\theta$ . . . (28)

In order to deduce the complete variation of the specific heats from these equations, it is necessary to make some assumption with regard to the variation of the specific heats with temperature. The assumption usually made is that the total kinetic energy of the molecules, including possible energy of rotation or vibration if the molecules consist of more than one atom, is proportional to the energy of translation in the case of an ideal gas. In the case of imperfect gases, all the available experimental evidence shows that the specific volume tends towards its ideal value, $V=R\theta/p$, in the limit, when the pressure is indefinitely reduced and the molecules are widely separated so as to eliminate the effects of their mutual actions. We may therefore reasonably assume that the *limiting* values of the specific heats at zero pressure do not vary with the temperature, provided that the molecule is stable and there is no dissociation. Denoting by S_0, s_0, these constant limiting values at $p=0$, we may obtain the values at any pressure by integrating the expressions (27) and (28) from ∞ to v and from 0 to p respectively. We thus obtain

$$S=S_0+n(n+1)pc/\theta \quad . \quad . \quad . \quad . \quad (29)$$
$$s=s_0+(n-1-nc/V)ncp/\theta \quad . \quad . \quad . \quad (30)$$

In working to a first approximation, the small term nc/V may be omitted in the expression for s.

The expression for the change of intrinsic energy E between any given limits $p_0\theta_0$ to $p\theta$ is readily found by substituting these

values of the specific heats in equations (11) or (13), and integrating between the given limits. We thus obtain

$$E - E_0 = s_0(\theta - \theta_0) - n(pc - p_0c_0) \quad . \quad . \quad (31)$$

The energy is less than that of an ideal gas by the term npc. If we imagine that the defect of volume c is due to the formation of molecular aggregates consisting of two or more single molecules, and if the kinetic energy of translation of any one of these aggregates is equal to that of one of the single molecules, it is clear that some energy must be lost in co-aggregating, but that the proportion lost will be different for different types of molecules and also for different types of co-aggregation. If two monatomic molecules, having energy of translation only, equivalent to 3 degrees of freedom, combined to form a diatomic molecule with 5 degrees of freedom, the energy lost would be $pc/2$ for co-aggregation, c, per unit mass. If two diatomic molecules, having each 5 degrees of freedom, combine to form a molecule with 6 degrees of freedom, we should have $n=2$, or the energy lost would be $2pc$ per unit mass. If the molecules and molecular aggregates were more complicated, and the number of degrees of freedom of the aggregates were limited to 6, or were the same as for single molecules, we should have $n=s_0/\mathrm{R}$. The loss of energy could not be greater than this on the simple kinetic theory, unless there were some evolution of latent heat of co-aggregation, due to the work done by the mutual attractions of the co-aggregating molecules.

It is not necessary to suppose that the co-aggregated molecules are permanently associated. They are continually changing partners, the ratio c/V representing approximately the ratio of the time during which any one molecule is paired to the time during which it is free. At higher densities it is probable that more complex aggregates would be formed, so that as the effect of the collisions became more important c would cease to be a function of the temperature only; experiment, indeed, shows this to be the case.

13. *Entropy.*—It follows from the definition of the absolute scale of temperature, as given in relations (2), that in passing at constant temperature θ from one adiabatic ϕ' (Fig. 1) to any other adiabatic ϕ'', the quotient H/θ of the heat absorbed by the temperature at which it is absorbed is the same for the same two adiabatics whatever the temperature of the isothermal path. This quotient is called the change of entropy, and may be denoted by $(\phi'' - \phi')$. In passing along an adiabatic there is no change of entropy, since no heat is absorbed. The adiabatics are lines of constant entropy, and are also called *Isentropics*. In virtue of relations (2), the change of entropy of a substance between any two states depends only on the initial and final states, and may be reckoned along any reversible path, not necessarily isothermal, by dividing each small increment of heat, dH, by the temperature, θ, at which it is acquired, and taking the sum or integral of the quotients, dH/θ, so obtained.

The expression for the change of entropy between any two states is found by dividing either of the expressions for dH in (8) by θ and integrating between the given limits, since dH/θ is a perfect differential. In the case of a solid or a liquid, the latent heat of isothermal expansion may often be neglected, and if the specific heat, s, be also taken as constant, we have simply $\phi - \phi_0 = s \log_e \theta/\theta_0$. If the substance at the temperature θ undergoes a change of state, absorbing latent heat, L, we have merely to add the term L/θ to the above expression. In the case of an ideal gas, $dp/d\theta$ at constant volume $= R/v$, and $dv/d\theta$ at constant pressure $= R/p$; thus we obtain the expressions for the change of entropy $\phi - \phi_0$ from the state $p_0\theta_0v_0$ to the state $p\theta v$,

$$\begin{aligned} \phi - \phi_0 &= s \log_e \theta/\theta_0 + R \log_e v/v_0 \\ &= S \log_e \theta/\theta_0 - R \log_e p/p_0 \end{aligned} \quad (32)$$

In the case of an imperfect gas or vapour, the above expressions are frequently employed, but a more accurate result may be obtained by employing equation (17) with the value of the specific heat, S, from (29), which gives the expression

$$\phi - \phi_0 = S_0 \log_e \theta/\theta_0 - R \log_e p/p_0 - n(cp/\theta - c_0p_0/\theta_0) \quad (33)$$

The state of a substance may be defined by means of the temperature and entropy as co-ordinates, instead of employing the pressure and volume as in the indicator diagram. This method of representation is applicable to certain kinds of problems, and has been developed by Macfarlane, Gray, and other writers in its application to the steam engine. (See ENGINES, vol. xxviii. p. 175 of this work; also Ewing, *Steam Engine;* Perry, *Steam Engine.*) Areas on the temperature-entropy or θ, ϕ diagram represent quantities of heat in the same way as areas on the indicator diagram represent quantities of work. The θ, ϕ diagram is useful in the study of heat waste and condensation, but from other points of view the utility of the conception of entropy as a "factor of heat" is limited by the fact that it does not correspond to any directly measurable physical property, but is merely a mathematical function arising from the form of the definition of absolute temperature. Changes of entropy must be calculated in terms of quantities of heat, and must be interpreted in a similar manner. The majority of thermodynamical problems may be treated without any reference to entropy, but it affords a convenient method of expression in abstract thermodynamics, especially in the consideration of irreversible processes and in reference to the conditions of equilibrium of heterogeneous systems.

14. *Irreversible Processes.*—In order that a process may be strictly reversible, it is necessary that the state of the working substance should be one of equilibrium at uniform pressure and temperature throughout. If heat passes "of itself" from a higher to a lower temperature by conduction, convection, or radiation, the transfer cannot be reversed without an expenditure of work. If mechanical work or kinetic energy is directly converted into heat by friction, reversal of the motion does not restore the energy so converted. In all such cases there is necessarily, by Carnot's principle, a loss of efficiency or available energy, accompanied by an increase of entropy, which serves as a convenient measure or criterion of the loss. A common illustration of an irreversible process is the expansion of a gas into a vacuum or against a pressure less than its own. In this case the work of expansion, pdv, is expended in the first instance in producing kinetic energy of motion of parts of the gas. If this could be co-ordinated and utilized without dissipation, the gas might conceivably be restored to its initial state; but in practice violent local differences of pressure and temperature are produced, the kinetic energy is rapidly converted into heat by viscous eddy friction, and residual differences of temperature are equalized by diffusion throughout the mass. Even if the expansion is adiabatic, in the sense that it takes place inside a non-conducting enclosure and no heat is supplied from external sources, it will not be isentropic, since the heat supplied by internal friction must be included in reckoning the change of entropy. Assuming that no heat is supplied from external sources and no external work is done, the intrinsic energy remains constant by the first law. The final state of the substance, when equilibrium has been restored, may be deduced from this condition, if the energy can be expressed in terms of the co-ordinates. But the line of constant energy on the diagram does not represent the path of the transformation, unless it be supposed to be effected in a series of infinitesimal steps between each of which the substance is restored to an equilibrium state. An irreversible process which permits a more complete experimental investigation is the steady flow of a fluid in a tube already referred to in section 10. If the tube is a perfect non-conductor, and if there are no eddies or frictional dissipation, the state of the substance at any point of the tube as to E, p, and v, is represented by the adiabatic or isentropic path, $dE = -pdv$. As the

section of the tube varies, the change of kinetic energy of flow, dU, is represented by $-vdp$. The flow in this case is reversible, and the state of the fluid is the same at points where the section of the tube is the same. In practice, however, there is always some frictional dissipation, accompanied by an increase of entropy and by a fall of pressure. In the limiting case of a long fine tube, the bore of which varies in such a manner that U is constant, the state of the substance along a line of flow may be represented by the line of constant total heat, $d(E+pv)=0$; but in the case of a porous plug or small throttling aperture, the steps of the process cannot be followed, though the final state is the same.

In any small reversible change in which the substance absorbs heat, dH, from external sources, the increase of entropy, $d\phi$, must be equal to dH/θ. If the change is not reversible, but the final state is the same, the change of entropy, $d\phi$, is the same, but it is no longer equal to dH/θ. By Carnot's principle, in all irreversible processes, dH/θ must be algebraically less than $d\phi$, otherwise it would be possible to devise a cycle more efficient than a reversible cycle. This affords a useful criterion (see ENERGETICS) between transformations which are impossible and those which are possible but irreversible. In the special case of a substance isolated from external heat supply, $dH=0$, the change of entropy is zero in a reversible process, but must be positive if the process is not reversible. The entropy cannot diminish. Any change involving decrease of entropy is impossible. The entropy tends to a maximum, and the state is one of stable equilibrium when the value of the entropy is the maximum value consistent with the conditions of the problem. This is the theorem of Clausius, but it cannot be usefully applied in practice on account of the difficulty of realizing experimentally the condition of heat-isolation, and because the equations to which it leads would often be difficult or impossible of solution.

15. *Heterogeneous Equilibrium.*—In a *system*, as distinguished from a homogeneous substance, consisting of two or more states or phases in equilibrium, a similar condition of equilibrium applies. In any spontaneous irreversible change, if the system is heat-isolated, there must be an increase of entropy. The total entropy of the system is found by multiplying the entropy per unit mass of the substance in each state by the mass existing in that state, and adding the products so obtained. The simplest case to consider is that of equilibrium between solid and liquid, or liquid and vapour. The more general case is discussed in the article ENERGETICS, and in the original memoirs of Willard Gibbs and others. Since the condition of heat-isolation is impracticable, the condition of maximum entropy cannot be directly applied, and it is necessary to find a more convenient method of expression. If dW is the external work done, dH the heat absorbed from external sources, and dE the increase of intrinsic energy, we have in all cases by the first law, $dH-dE=dW$. Since $\theta d\phi$ cannot be less than dH, the difference $(\theta d\phi - dE)$ cannot be less than dW. This inequality holds in all cases, but cannot in general be applied to an irreversible change, because $\theta d\phi$ is not a perfect differential, and cannot be evaluated without a knowledge of the path or process of transformation. In the special case, however, in which the transformation is conducted in an isothermal enclosure, a common condition easily realized in practice, the temperature at the end of the transformation is reduced to its initial value throughout the substance. The value of $\theta d\phi$ is then the same as $d(\theta\phi)$, which is a perfect differential, so that the condition may be written $d(\phi\theta - E)=dW$. The condition in this form can be readily applied provided that the external work dW can be measured. There are two special cases of importance:—(*a*) If the volume is constant, or $dW=0$, the value of the function $(\theta\phi - E)$ cannot diminish, or $(E-\theta\phi)$ cannot increase, if the temperature is kept constant. This function may be represented, for each state or phase of the system considered, by an area on the indicator diagram similar to that representing the intrinsic energy, E. The product $\theta\phi$ may be represented at any point such as D in Fig. 1 by the whole area θ''DZ'VO under the isothermal θ''D and the adiabatic DZ', bounded by the axes of pressure and volume. The intrinsic energy, E, is similarly represented by the area DZ'Vd under the adiabatic to the right of the isometric Dd. The difference $\theta\phi - E$ is represented by the area θ''DdO to the left of the isometric Dd under the isothermal θ''D. The increment of this area (or the decrement of the negative area $E-\theta\phi$) at constant temperature represents the external work obtainable from the substance in isothermal expansion, in the same way that the decrement of the intrinsic energy represents the work done in adiabatic expansion. The function $J=E-\theta\phi$, has been called the "free energy" of the substance by Helmholtz, and $\theta\phi$ the "bound energy." These functions do not, however, represent energy existing in the substance, like the intrinsic energy; but the increment of $\theta\phi$ represents heat supplied to, and the decrement of $(E-\theta\phi)$ represents work obtainable from, the substance when the temperature is kept constant. The condition of stable equilibrium of a system at constant temperature and volume is that the total J should be a minimum. This function is also called the "thermodynamic potential at constant volume" from the analogy with the condition of minimum potential energy as the criterion of stable equilibrium in statics.

As an example, we may apply this condition to the case of change of state. If J', J'' represent the values of the function for unit mass of the substance of specific volumes v' and v'' in the two states at temperature θ and pressure p, and if a mass m is in the state v', and $1-m$ in the state v'', the value of J for unit mass of the mixture is $mJ'+(1-m)J''$. This must be a minimum in the state of equilibrium at constant temperature. Since the volume is constant, we have the condition $mv'+(1-m)v''=$constant. Since $dJ=-\phi d\theta - pdv$, we have also the relations $dJ'/dv'=-p=dJ''/dv''$, at constant temperature. Putting $dJ/dm=0$ at constant volume, we obtain as the condition of equilibrium of the two states $J'+p'v'=J''+p''v''$. This may be interpreted as the equation of the border curve giving the relation between p and θ, but is more easily obtained by considering the equilibrium at constant pressure instead of constant volume.

(*b*) The second case, which is of greater practical utility, is that in which the external pressure, p, is kept constant. In this case $dW=pdv=d(pv)$, a perfect differential, so that the external work done is known from the initial and final states. In any possible transformation $d(\theta\phi - E)$ cannot be less than $d(pv)$, or the function $(E-\theta\phi+pv)=G$ cannot increase. The condition of stable equilibrium is that G should be a minimum, for which reason it has been called the "thermodynamic potential at constant pressure." The product pv for any state such as D in Fig. 1 is represented by the rectangle MDdO, bounded by the isopiestic and the isometric through D. The function G is represented by the negative area θ''DM under the isothermal, bounded by the isopiestic DM and the axis of pressure. The increment of $\theta\phi$ is always greater than that of the total heat $F=E+pv$, except in the special case of an equilibrium change at constant temperature and pressure, in which case both are equal to the heat absorbed in the change, and the function G remains constant. This is geometrically obvious from the form of the area representing the function on the indicator diagram, and also follows directly from the first law. The simplest application of the thermodynamic potential is to questions of change of state. If ϕ', E', v'; and ϕ'', E'', v'', refer to

unit mass of the substance in the first and second states respectively in equilibrium at a temperature θ and pressure p, the heat absorbed, L, per unit mass in a change from the first to the second state is, by definition of the entropy, equal to $\theta(\phi''-\phi')$, and this by the first law is equal to the change of intrinsic energy, $E''-E'$, plus the external work done, $p(v''-v')$, *i.e.*, to the change of total heat, $F''-F'$. If G' and G'' are the values of the function G for the two states in equilibrium at the same pressure and temperature, we must have $G'=G''$. Assuming the function G to be expressed in terms of p and θ, this condition represents the relation between p and θ corresponding to equilibrium between the two states, which is the solution of the relation $(v''-v')dp/d\theta=L/\theta$, (5). The direct integration of this equation requires that L and $v''-v'$ should be known as functions of p and θ, and cannot generally be performed. As an example of one of the few cases where a complete solution is possible, we may take the comparatively simple case equation (17), already considered, which is approximately true for the majority of vapours at moderate pressures.

Writing formulæ (31) and (33) for the energy and entropy with indeterminate constants A and B, instead of taking them between limits, we obtain the following expressions for the thermodynamic functions in the case of the vapour:—

$$\phi''=S_0\log_e\theta-R\log_e p-ncp/\theta+A'' \quad . \quad . \quad . \quad . \quad (34)$$
$$E''=s_0\theta-ncp+B'' \quad . \quad . \quad . \quad . \quad . \quad . \quad (35)$$
$$F''=S_0\theta-(n+1)cp+bp+B'' \quad . \quad . \quad . \quad . \quad (36)$$
$$G''=S_0\theta(1-\log_e\theta)+R\theta\log_e p-(c-b)p-A''\theta+B'' \quad . \quad (37)$$
$$J''=s_0\theta-S_0\theta\log_e\theta+R\theta\log_e p-A''\theta+B'' \quad . \quad . \quad (38)$$

The function J'' may be expressed in terms of θ and v by writing for p its value, namely, $R\theta/(v+c-b)$. We have also in any case the relations

$$dG''/d\theta\ (p\ \text{const})=\phi''=dJ''/d\theta\ (v\ \text{const}) \quad . \quad . \quad (39)$$
$$dG''/dp\ (\theta\ \text{const})=v,\ dJ''/dv\ (\theta\ \text{const})=p \quad . \quad . \quad (40)$$

And all the properties of the substance may be expressed in terms of G or J and their partial differential coefficients. The values of the corresponding functions for the liquid or solid cannot be accurately expressed, as the theoretical variation of the specific heat is unknown, but if we take the specific heat at constant pressure s' to be approximately constant, and observe the small residual variation dh of the total heat, we may write

$$F'=s'\theta+dh+B' \quad . \quad . \quad . \quad . \quad . \quad . \quad (41)$$
$$\phi'=s'\log_e\theta+d\phi+A' \quad . \quad . \quad . \quad . \quad . \quad (42)$$
$$G'=s'\theta(1-\log_e\theta)+(dh-\theta d\phi)-A'\theta+B' \quad . \quad . \quad (43)$$

where $d\phi$ is the corresponding residual variation of ϕ', and is easily calculated from a table of values of h.

To find the border curve of equilibrium between the two states, giving the saturation pressure as a function of the temperature, we have merely to equate the values of G' and G''. Rearranging the terms, and dividing throughout by θ, we obtain an equation of the form

$$R\log_e p=A-B/\theta-(s'-S_0)\log_e\theta+(c-b)p/\theta+(dh/\theta-d\phi) \quad . \quad (44)$$

in which $B=B''-B'$, and $A=A''-A'+s'-S_0$. The value of A is determined by observing the value of θ_0 at some known pressure p_0, *e.g.*, at the boiling-point. The value of B is determined by observing the latent heat, $L_0=F'''_0-F''_0$, which gives

$$B=B''-B'=L_0+(s'-S_0)\theta_0+(n+1)c_0p_0-bp_0+dh_0 \quad . \quad (45)$$

This constant may be called the absolute latent heat, as it expresses the thermal value of the change of state in a manner independent of temperature.

The term $(dh/\theta-d\phi)$ depending on the variation of the specific heat of the liquid may be made very small in the case of water by a proper choice of the constant s'. It is of the same order as the probable errors of observation, and may be neglected in practice. (See VAPORIZATION, § 12.) The expression for $R\log p$ for an imperfect gas of this type differs from that for a perfect gas only by the addition of the term $(c-b)p/\theta$. This simple result is generally true, and the corresponding expressions for G'' and J'' are valid, provided that $c-b$ in formula (17) is a function of the temperature only. It is not necessary to suppose that c varies inversely as the nth power of the temperature, and that b is constant, as assumed in deducing the expressions for ϕ, E, and F.

Although the value of G in any case cannot be found without that of ϕ, and although the consideration of the properties of the thermodynamic potential cannot in any case lead to results which are not directly deducible from the two fundamental laws, it affords a convenient method of formal expression in abstract thermodynamics for the condition of equilibrium between different phases, or the criterion of the possibility of a transformation. For such purely abstract purposes, the possibility of numerical evaluation of the function is of secondary importance, and it is often possible to make qualitative deductions with regard to the general nature of a transformation without any knowledge of the actual form of the function. A more common method of procedure, however, is to infer the general relations of the thermodynamic potential from a consideration of the phenomena of equilibrium.

It is often possible to heat a liquid at atmospheric pressure considerably above its boiling-point, especially if it be not exposed to vapour or gas. It is similarly possible to cool a vapour considerably below its condensing-point, in the absence of nuclei, without condensation occurring. Under such conditions, boiling of the liquid or condensation of the vapour may be induced, if they are brought in contact or in various other ways, but is an irreversible process involving local differences of pressure and temperature, which cannot be fully represented on the indicator diagram, since the condition is not one of equilibrium throughout the substance. In such cases there is always dissipation of available energy in friction and diffusion before the equilibrium state is reached, and the value of the function G for the mixture is diminished. The direction of the change of state which occurs may be determined by observing whether G' is greater than G'', or *vice versâ*.

As it would be impossible within the limits of this article to illustrate or explain adequately all the applications which have been made of the principles of thermodynamics, it has been necessary to select such illustrations only as are required for other reasons, or could not be found elsewhere. For fuller details and explanations of the elements of the subject, the reader must be referred to general treatises such as Baynes's *Thermodynamics* (Oxford), Tait's *Thermodynamics* (Edinburgh), Maxwell's *Theory of Heat* (London), Parker's *Thermodynamics* (Cambridge), Clausius's *Mechanical Theory of Heat* (translated by Browne, London), and Preston's *Theory of Heat* (London). One or two chapters on the subject are also generally included in treatises on the steam engine, or other heat engines, such as those of Rankine, Perry, or Ewing. Of greater interest, particularly from a historical point of view, are the original papers of Joule, Thomson, and Rankine, some of which have been reprinted in a collected form. A more complete and more elaborate treatment of the subject will be found in foreign treatises, such as those of Clausius, Zeuner, Duhem, Bertrand, Planck, and others.

Alphabetical Index of Symbols employed.

θ, Thermodynamic or absolute temperature.
ϕ, Entropy. Section 13.
b, Covolume of molecules of gas. Equation (17).
c, c_0, Co-aggregation volume per unit mass. Equation (17).
e, Base of Napierian logarithms.
E, Intrinsic energy per unit mass. Section 2.
$F=E+pv$, Total heat. Section 7.
G, J, Thermodynamic potential functions. Section 15.
H, Quantity of heat (in mechanical units). Section 2.
K, k, Adiabatic and isothermal elasticities. Equation (7).
L, Latent heat of fusion or vaporization. Equation (5).
M, Molecular weight. Section 8.
m, Mass of substance or molecule.
n, Index in expression for c. Equation (17).
p, Pressure of fluid. p_0, Initial pressure.
$R=S_0-s_0$, Constant in gas-equation (17).
S, Specific heat of gas at constant pressure.
S_0, Limiting value of S when $p=0$. Section 12.
s, Specific heat of gas at constant volume.
s_0, Limiting value of s when $p=0$. Section 12.
s', s'', Specific heat under other conditions. Equation (5).
U, Kinetic energy of flow of fluid. Section 10.
u, Mean velocity of gaseous molecules. Section 8.
$V=R\theta/p$, Ideal volume of gas per unit mass. Equation (17).
v, Specific volume of fluid, reciprocal of density.
W, External work done by fluid.

Thermoelectricity.—The account of this subject given in the article ELECTRICITY, *Ency. Brit.*, vol. viii. p. 94, brings our knowledge of the phenomena down to the epoch of Tait's theory and experiments. The present article gives a summary of the results of the older work, in order to make the discussion of later theories and researches intelligible.

§ 1. *Fundamental Phenomena.*—Volta (1801) showed that although a separation of the two electricities was produced by the contact of two different metals (*Volta Effect*), which could be detected by a sensitive electrometer, a continuous current of corresponding magnitude could not be produced in a purely metallic circuit without the interposition of a liquid, because the electromotive force at one junction was exactly balanced by an equal and opposite force at the other. Seebeck (1822), employing a galvanometer then recently invented, which was more suited for the detection of small electromotive forces, found that a current was produced if the junctions of the two metals were at different temperatures. He explained this effect by supposing that the Volta contact E.M.F. varied with the temperature, so that the exact balance was destroyed by unequal heating. The intensity of the current, C, for any given pair of metals was found to vary directly as the difference of temperature, $t-t'$, between the hot and cold junctions, and inversely as the resistance, R, of the circuit. We conclude by applying Ohm's law that the electromotive force, E, of the thermocouple may be approximately represented for small differences of temperature by the formula

$$E=CR=p\,(t-t') \quad . \quad . \quad . \quad . \quad (1)$$

§ 2. *Thermoelectric Power, Series, Inversion.*—The limiting value, dE/dt, of the coefficient, p, for an infinitesimal difference, dt, between the junctions is called the *Thermoelectric Power* of the couple. One metal (A) is said to be thermoelectrically positive to another (B), if positive electricity flows from A to B across the cold junction when the circuit is completed. The opposite convention is sometimes adopted, but the above is the most convenient in practice, as the circuit is generally broken at or near the cold junction for the insertion of the galvanometer. Seebeck found that the metals could be arranged in a *Thermoelectric Series*, in the order of their power when combined with any one metal, such that the power of any thermocouple p, composed of the metals A and B, was equal to the algebraic difference $(p'-p'')$ of their powers when combined with the standard metal C. The order of the metals in this series was found to be different from that in the corresponding Volta series, and to be considerably affected by variations in purity, hardness, and other physical conditions. Cumming shortly afterwards discovered the phenomenon of *Thermoelectric Inversion*, or the change of the order of the metals in the thermoelectric series at different temperatures. Copper, for instance, is negative to iron at ordinary temperatures, but is positive to it at 300° C. or above. The E.M.F. of a copper-iron thermocouple reaches a maximum when the temperature of the hot junction is raised to 270° C., at which temperature the thermoelectric power vanishes and the metals are said to be *neutral* to one another. Beyond this point the E.M.F. diminishes, vanishing and changing sign when the temperature of the hot junction is nearly as much above the neutral point as the temperature of the cold junction is below it. Similar phenomena occur in the case of many other couples, and it is found that the thermoelectric power p is not in general a constant, and that the simple linear formula (1) is applicable only for small differences of temperature. More accurately it may be stated that the thermo-E.M.F. in any given circuit containing a series of different metals is a function of the temperatures of the junctions only, and is independent of the distribution of the temperature at any intermediate points, provided that each of the metals in the series is of uniform quality. This statement admits of the simple mathematical expression

$$E=\int_{t_0}^{t'} p'dt+\int_{t'}^{t''} p''dt+\&c. \quad . \quad . \quad . \quad (2);$$

where p', p , &c., are the thermoelectric powers of the metals, and t_0, t', t," &c., the temperatures of the junctions. There are some special cases of sufficient practical importance to be separately stated.

§ 3. *Homogeneous Circuit. Strain Hysteresis.*—In a circuit consisting of a single metal, no current can be produced by variations of temperature, provided that the metal is not thereby strained or altered. This was particularly demonstrated by the experiments of Magnus. The effects produced by abrupt changes of temperature or section, or by pressing together pieces of the same metal at different temperatures, are probably to be explained as effects of strain. A number of interesting effects of this nature have been investigated by Thomson, Le Roux, Tait, and others, but the theory has not as yet been fully developed. An interesting example is furnished by an experiment due to Trouton (*Proc. R. S. Dub.*, 1886). A piece of iron or steel wire in the circuit of a galvanometer is heated in a flame to bright redness at any point. No effect is noticed so long as the flame is stationary, but if the flame be moved slowly in one direction a current is observed, which changes its direction with the direction of motion of the flame. The explanation of this phenomenon is that the metal is transformed at a red heat into another modification, as is proved by simultaneous changes in its magnetic and electrical properties. The change from one state to the other takes place at a higher temperature on heating than on cooling. The junctions of the magnetic and the non-magnetic steel are therefore at different temperatures if the flame is moved, and a current is produced just as if a piece of different metal with junctions at different temperatures had been introduced into the circuit. Other effects of "hysteresis" occur in alloys of iron, which have been recently studied by Barrett (*Trans. R. S. Dub.*, Jan. 1900).

§ 4. *Law of Successive Temperatures.*—The E.M.F. of a given couple between any temperatures t' and t'' is the algebraic sum of the E.M.F. between t' and any other temperature t and the E.M.F. between t and t''. A useful result of this law is that it is sufficient to keep one junction always at some convenient standard temperature, such as 0° C., and to tabulate only the values of the E.M.F. in the circuit corresponding to different temperatures of the other junction.

§ 5. *Law of Intermediate Metals.*—A thermoelectric circuit may be cut at any point and a wire of some other metal introduced without altering the E.M.F. in the circuit, provided that the two junctions with the metal introduced are kept at the same temperature. This law is commonly applied in connecting a thermocouple to a galvanometer with coils of copper wire, the junctions of the copper wires with the other metals being placed side by side in a vessel of water or otherwise kept at the same temperature. Another way of stating this law, which, though apparently quite different, is really equivalent in effect, is the following. The E.M.F. of any couple, AB, for any given limits of temperature is the algebraic sum of the E.M.F.s between the same limits of temperature of the couples BC and CA formed with any other metal C. It is for this reason unnecessary to tabulate the E.M.F.s

of all possible combinations of metals, since the E.M.F. of any couple can be at once deduced by addition from the values given by its components with a single standard metal. Different observers have chosen different metals as the standard of reference. Tait and Fleming select lead on account of the smallness of the Thomson effect in it, as observed by Le Roux. Noll adopts mercury because it is easily purified, and its physical condition in the liquid state is determinate; there is, however, a discontinuity involved in passing from the liquid to the solid state at a temperature of $-40°$ C., and it cannot be used at all with some metals, such as lead, on account of the rapidity with which it dissolves them. Both lead and mercury have the disadvantage that they cannot be employed for temperatures much above 300° C. Of all metals, copper is the most generally convenient, as it is always employed in electrical connexions and is easily obtained in the annealed state of uniform purity. For high temperature work it is necessary to employ platinum, which would be an ideal standard for all purposes on account of its constancy and infusibility, did not the thermoelectric properties of different specimens differ considerably.

§ 6. *Thermoelectric Formulæ.*—On the basis of the principles stated above, the most obvious method of tabulating the observations would be to give the values E_t of the E.M.F. between 0° C. and t for each metal against the standard. This involves no assumptions as to the law of variation of E.M.F. with temperature, but is somewhat cumbrous. In the majority of cases it is found that the observations can be represented within the limits of experimental error by a fairly simple empirical formula, at least for moderate ranges of temperature. The following formulæ are some of those employed for this purpose by different observers:—

$E_t=bt+ct^2$	(Avenarius, 1863.)
$E_t=at+bt^2+ct^3$ . . .	(General type.)
$log\ E=a+b/T+c\ log\ T$ . .	(Becquerel, 1863.)
$E_{(t-t')}=c(t-t')(2t°-(t+t'))$.	(Tait, 1870.)
$E_t+E_{t°}=10^{a+bt}+10^{a'+b't}$.	(Barus, 1889.)
$t=aE+bE^2+cE^3$ . . .	(Holborn and Wien, 1892.)
$E_{(t-t')}=b(t-t')^{4/3}$ . . .	(Paschen, 1893.)
$E_{(t-t')}=a(t-t')+b(t-t')^2$.	(Steele, 1894.)
$E_{(T-T')}=mT^n-mT'^n$, $E_t=mt^n$	(Holman, 1896.)
$E_t=bt+c\ log\ T/273$, $(c=Ts.)$.	(Stansfield, 1898.)
$E_t=-a+bt+ct^2$ . . .	(Holborn and Day, 1899.)
$E_t=at+ct^2+s°(T\ log_e T-273\ log_e 273)$.	

(Where $s=s°+2cT$, and c is small. See sec. 15.)

For moderate ranges of temperature the binomial formula of Avenarius is generally sufficient, and has been employed by many observers. It is figured by Avenarius (*Pogg. Ann.*, 119, p. 406) as a semi-circle, but it is really a parabola with its axis parallel to the axis of E, and its vertex at the point $t=-b/2c$, which gives the neutral temperature. We have also the relations $dE/dt=b+2ct$ and $d^2E/dt^2=2c$. The first relation gives the thermoelectric power p at any temperature, and is probably the most convenient method of stating results in all cases in which this formula is applicable. A discussion of some of the exponential formulæ is given by Holman (*Phil. Mag.*, 41, p. 465, June 1896).

§ 7. *Experimental Results.*—In the following comparative table of the results of different observers the values are referred to lead. Before the time of Tait's researches such data were of little interest or value, on account of insufficient care in securing the purity of the materials tested; but increased facilities in this respect, combined with great improvements in electrical measurements, have put the question on a different footing. The comparison of independent results shows in many cases a remarkable concordance, and the data are becoming of great value for the testing of various theories of the relations between heat and electricity.

TABLE I.—THERMOELECTRIC POWER, $p=dE/dt$, IN MICROVOLTS AT 50° C. OF PURE METALS WITH RESPECT TO LEAD. (The mean change, $2c=d^2E/dt^2$, of the thermoelectric power per degree C. over the range covered by the experiments, is added in each case.)

Explanation of Table.—The figures marked with an asterisk represent discrepancies which are probably caused by impurities in the specimens. At the time of Tait's work in 1873 it was difficult, if not impossible, in many cases to secure pure materials. The work of the other three observers dates from 1894–95. The value of the thermoelectric power dE/dt at 50° C. is taken as the mean value between 0° and 100° C., over which range it can be most accurately determined. The values of d^2E/dt^2 agree as well as can be expected, considering the difference of the ranges of temperature and the great variety in the methods of observation adopted; they are calculated assuming the parabolic formula, which is certainly in many cases inadequate. Noll's values apply to the temperature of +100° C., Dewar and Fleming's to that of −100° C., approximately.

In using the above table to find the value of E or dE/dt at any temperature or between any limits, denoting by p the value of dE/dt at 50° C., and by $2c$ the constant value of the second coefficient, we have the following equations:—

$$dE/dt=p+2c\ (t-50),\ \text{at any temperature } t,\ \text{Cent.} \quad . \quad (3),$$

$$E_{(t-t')}=(t-t')\ (p+c\ (t+t'-100)) \quad . \quad . \quad . \quad . \quad (4),$$

for the E.M.F. between any temperatures t and t'.

§ 8. *Methods of Observation.*—In Tait's observations the E.M.F. was measured by the deflection of a mirror galvanometer, and the temperature by means of a mercury thermometer or an auxiliary thermocouple. He states that the deviations from the formula were "quite within the limits of error introduced by the alteration of the resistance of the circuit with rise of temperature, the deviations of the mercury thermometers from the absolute scale, and the non-correction of the indications of the thermometer for the long column of mercury not immersed in the hot oil round the junctions." The latter correction may amount to about 10° C. at 350°. Later observers have generally employed a balance method (some modification of the Potentiometer or Poggendorf balance) for measuring the E.M.F. The range of Steele's observations was too small to show any certain deviation from the formula, but he

notes capricious changes attributed to change of condition of the wires. Noll employed mercury thermometers, but as he worked over a small range with vapour baths, it is probable that he did not experience any trouble from immersion corrections. He does not record any systematic deviations from the formula. Dewar and Fleming, working at very low temperatures, were compelled to use the platinum thermometer, and expressed their results in terms of the platinum scale. Their observations were probably free from immersion errors, but they record some deviations from the formula which they consider to be beyond the possible limits of error of their work. The writer has reduced their results to the scale of the gas thermometer, assuming the boiling-point of oxygen to be −182·5° C.

§ 9. *Peltier Effect.*—The discovery by Peltier (1834) that heat is absorbed at the junction of two metals by passing a current through it in the same direction as the current produced by heating it, was recognized by Joule as affording a clue to the source of the energy of the current by the application of the principles of thermodynamics. Unlike the frictional generation of heat due to the resistance of the conductor, which Joule (1841) proved to be proportional to the square of the current, the Peltier effect is reversible with the current, and being directly proportional to the first power of the current, changes sign when the current is reversed. The effect is most easily shown by connecting a voltaic cell to a thermopile for a short interval, then quickly (by means of a suitable key, such as a Pohl commutator with the cross connectors removed) disconnecting the pile from the cell and connecting it to a galvanometer, which will indicate a current in the reverse direction through the pile, and approximately proportional to the original current in intensity, provided that the other conditions of the experiment are constant. It was by an experiment of this kind that Icilius (1853) verified the proportionality of the heat absorbed or generated to the first power of the current. It had been observed by Peltier and Becquerel that the intensity of the effect depended on the thermoelectric power of the junction and was independent of its form or dimensions. The order of the metals in respect of the Peltier effect was found to be the same as the thermoelectric series. But on account of the difficulty of the measurements involved, the verification of the accurate relation between the Peltier effect and thermoelectric power was left to more recent times. If C is the intensity of the current through a simple thermocouple, the junctions of which are at temperatures t and t', a quantity of heat, $P \times C$, is absorbed by the passage of the current per second at the hot junction, t, and a quantity, $P' \times C$, is evolved at the cold junction, t'. The coefficients, P and P', are called coefficients of the Peltier effect, and may be stated in calories or joules per ampere-second. The Peltier coefficient may also be expressed in volts or microvolts, and may be regarded as the measure of an E.M.F. located at the junction, and transforming heat into electrical energy or *vice versâ*. If R is the whole resistance of the circuit, and E the E.M.F. of the couple, and if the flow of the current does not produce any other thermal effects in the circuit besides the Joule and Peltier effects, we should find by applying the principle of the conservation of energy, *i.e.*, by equating the balance of the heat absorbed by the Peltier effects to the heat generated in the circuit by the Joule effect,

$$(P-P')\,C = C^2R = EC, \text{ whence } E = P - P'. \quad . \quad (5)$$

If we might also regard the couple as a reversible thermodynamic engine for converting heat into work, and might neglect irreversible effects, such as conduction, which are independent of the current, we should expect to find the ratio of the heat absorbed at the hot junction to the heat evolved at the cold junction, namely P/P', to be the same as the ratio T/T' of the absolute temperatures of the junctions. This would lead to the conclusion given by Clausius (1853) that the Peltier effect varied directly as the absolute temperature, and that the E.M.F. of the couple should be directly proportional to the difference of temperature between the junctions.

§ 10. *Thomson Effect.*—Thomson (Lord Kelvin) had already pointed out (*Proc. R. S. Ed.*, 1851) that this conclusion was inconsistent with the known facts of thermoelectric inversion. (1) The E.M.F. was not a linear function of the temperature difference. (2) If the Peltier effect was proportional to the thermoelectric power and changed sign with it, as all experiments appeared to indicate, there would be no absorption of heat in the circuit due to the Peltier effect, and therefore no thermal source to account for the energy of the current, in the case in which the hot junction was at or above the neutral temperature. He therefore predicted that there must be a reversible absorption of heat in some other part of the circuit due to the flow of the current through the unequally-heated conductors. He succeeded a few years afterwards in verifying this remarkable prediction by the experimental demonstration that a current of positive electricity flowing from hot to cold in iron produced an absorption of heat, as though it possessed *negative* specific heat in the metal iron. He also succeeded in showing that a current from hot to cold evolved heat in copper, but the effect was smaller and more difficult to observe than in iron.

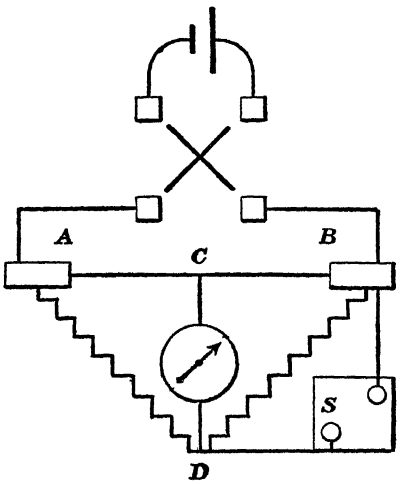

FIG. 1.—Diagram of Apparatus for Demonstrating the Thomson Effect.

The Thomson effect may be readily demonstrated as a lecture experiment by the following method (Fig. 1). A piece of wire (No. 28) about 4 cm. long is soldered at either end A, B to thick wires (No. 12), and is heated 100° to 150° C. by a steady current from a storage cell adjusted by a suitable rheostat. The experimental wire AB is connected in parallel with about 2 metres of thicker wire (No. 22), which is not appreciably heated. A low-resistance galvanometer is connected by a very fine wire (2 to 3 mils) to the centre C of the experimental wire AB, and also to the middle point D of the parallel wire so as to form a Wheatstone bridge. The balance is adjusted by shunting either AD or BD with a box containing 20 to 100 ohms. All the wires in the quadrilateral must be of the same metal as AB, to avoid accidental thermoelectric effects which would obscure the result. If the current flows from A to B there will be heat absorbed in AC and evolved in CB by the Thomson effect, if the specific heat of electricity in AB is positive as in copper. When the current is reversed, the temperature of AC will be raised and that of CB lowered by the reversal of the effect. This will disturb the resistance balance by an amount which can be measured by the deflection of the galvanometer, or by the change of the shunt-box, S, required to restore the balance. Owing to the small size of the experimental wire, the method is very quick and sensitive, and the apparatus can be set up in a few minutes when once the experimental quadrilaterals have been made. It works very well with platinum, iron, and copper. It was applied with elaborate modifications by the writer in 1886 to determine the value of the Thomson effect in platinum in absolute measure, and has recently been applied with further improvements by King to measure the effect in copper.

§ 11. *Thomson's Theory.*—Taking account of the Thomson effect, the thermodynamical theory of the couple was satisfactorily completed by Thomson (*Trans. R. S. Ed.*,

1854). If the quantity of heat absorbed and converted into electrical energy, when unit quantity of electricity (one ampere-second) flows from cold to hot through a difference of temperature, dt, be represented by sdt, the coefficient s is called the specific heat of electricity in the metal, or simply the coefficient of the Thomson effect. Like the Peltier coefficient, it may be measured in joules or calories per ampere-second per degree, or more conveniently and simply in microvolts per degree.

Consider an elementary couple of two metals A and B for which s has the values s' and s'' respectively, with junctions at the temperatures T and $T+dT$ (absolute), at which the coefficients of the Peltier effect are P and $P+dP$. Equating the quantity of heat absorbed to the quantity of electrical energy generated, we have by the first law of thermodynamics the relation

$$dE/dT = dP/dT + (s' - s'') \quad . \quad . \quad . \quad (6)$$

If we apply the second law, regarding the couple as a reversible engine, and considering only the reversible effects, we obtain

$$(s' - s'')/T = -d(p/T)/dT \quad . \quad . \quad . \quad (7)$$

Eliminating $(s' - s'')$ we find for the Peltier effect

$$P = TdE/dT = Tp \quad . \quad . \quad . \quad . \quad (8)$$

Whence we obtain for the difference of the specific heats

$$(s' - s'') = -Td^2E/dT^2 = -Tdp/dT \quad . \quad . \quad (9)$$

From these relations we observe that the Peltier effect P, and the difference of the Thomson effects $(s' - s'')$, for any two metals are easily deduced from the tabulated values of dE/dt and d^2E/dt^2 respectively. The signs in the above equations are chosen on the assumption that positive electricity flows from cold to hot in the metal s'. The signs of the Peltier and Thomson effects will be the same as the signs of the coefficients given in Table I., if we suppose the metal s' to be lead, and assume that the value of s' may be taken as zero at all temperatures.

§ 12. *Experimental Verification of Thomson's Theory.*—In order to justify the assumption involved in the application of the second law of thermodynamics to the theory of the thermocouple in the manner above specified, it would be necessary and sufficient, as Thomson pointed out (*Phil. Mag.*, December 1852), to make experiments to verify quantitatively the relation $P/T = dE/dT$ between the Peltier effect and the thermoelectric power. A qualitative relation was known at that time to exist, but no absolute measurements of sufficient accuracy had been made. The most accurate measurements of the heat absorption due to the Peltier effect at present available are probably those of Jahn (*Wied. Ann.*, 34, p. 755, 1888). He enclosed various metallic junctions in a Bunsen ice calorimeter, and observed the evolution of heat per hour with a current of about 1·6 amperes in either direction. The Peltier effect was only a small fraction of the total effect, but could be separated from the Joule effect owing to the reversal of the current. The values of dE/dT for *the same specimens* of metal at 0° C. were determined by experiments between +20° C. and −20° C. The results of his observations are contained in the following table, heat absorbed being reckoned positive as in Table I.:—

TABLE II.

Thermo-couple.	dE/dT Microvolts per deg.	$P = Td\,E/dT$ Microvolts at 0° C.	Heat calc. Calories per hour.	Heat observ'd Calories per hour.
Cu-Ag	+2·12	+579	+0·495	+0·413
Cu-Fe	+11·28	+3079	+2·640	+3·163
Cu-Pt	−1·40	−382	−0·327	−0·320
Cu-Zn	+1·51	+412	+0·353	+0·585
Cu-Cd	+2·64	+721	+0·617	+0·616
Cu-Ni	−20·03	−5468	−4·680	−4·362

The agreement between the observed and calculated values in the last two columns is as good as can be expected considering the great difficulty of measuring such small quantities of heat. The analogous reversible heat effects which occur at the junction of a metal and an electrolyte were also investigated by Jahn, but he did not succeed in obtaining so complete an agreement with theory in this case.

§ 13. *Tait's Hypothesis.*—From general considerations concerning minimum dissipation of energy (*Proc. R. S. Ed.*, 1867–68), Tait was led to the conclusion that "the thermal and electric conductivities of metals varied inversely as the absolute temperature, and that the specific heat of electricity was directly proportional to the same." Subsequent experiments led him to doubt this conclusion as regards conductivity, but his thermoelectric experiments (*Proc. R. S. Ed.*, Dec. 1870) appeared to be in good agreement with it. If we adopt this hypothesis, and substitute $s = 2cT$, where c is a constant, in the fundamental equation (9), we obtain at once $d^2E/dT^2 = -2(c' - c'')$, which is immediately integrable, and gives

$$dE/dt = p = 2(t_0 - t)(c' - c'') \quad . \quad . \quad (10),$$

$$E_{t-t'} = (t - t')(c' - c'')\{2t_0 - (t + t')\} \quad . \quad . \quad (11),$$

where t_0 is the temperature of the neutral point at which $dE/dt = 0$. This is the equation to a parabola, and is equivalent to the empirical formula of Avenarius, with this difference, that in Tait's formula the constants have all a simple and direct interpretation in relation to the theory. Tait's theory and formula were subsequently assimilated by Avenarius (*Pogg. Ann.*, 149, p. 372, 1873), and are now generally attributed to Avenarius in foreign periodicals.

In accordance with this hypothesis, the curves representing the variations of thermoelectric power, dE/dt, with temperature are straight lines, the slope of which for any couple is equal to the difference of the constants $2(c' - c'')$. The diagram constructed by Tait on this principle is fully explained and illustrated in the article ELECTRICITY (*Ency. Brit.*, vol. viii. p. 97). It has since been generally adopted as embodying in a simple form the fundamental phenomena of thermoelectricity.

§ 14. *Experimental Verification.*—Tait's verification of this hypothesis consisted in showing that the experimental curves of E.M.F. were parabolas in most cases within the limits of error of his observations. He records, however, certain notable divergencies, particularly in the case of iron and nickel, and many others have since come to light from other observations. It should also be remarked that even if the curves were not parabolas, it

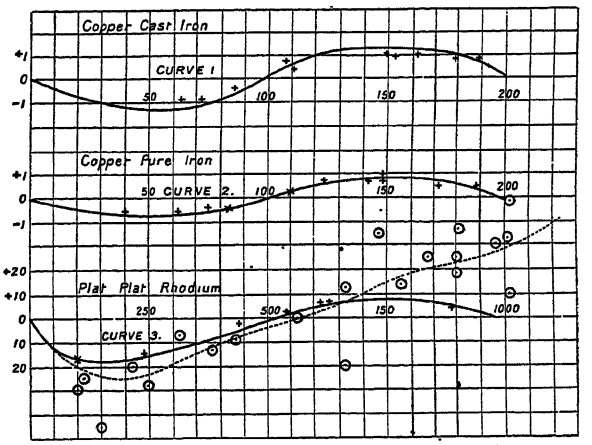

FIG. 2.—Temperature by Thermocouple. Difference from Tait's formula.

would always be possible to draw parabolas to agree closely with the observations over a restricted range of temperature. When the question is tested more carefully, either by taking more accurate measurements of temperature, or by extending the observations over a wider range, it is found that there are systematic deviations from the parabola in the majority of cases, which cannot be explained by errors of experiment. A more accurate verification of these relations, both at high and low extremes of temperature, has become possible of late years owing to the development of the theory and application of the platinum resistance thermometer. (See THERMOMETRY.) The curves in Fig. 2 illustrate the differences from the parabolic formula, measured in degrees of temperature, as observed by Tory (*B. A. Report*, 1897). The deviations for the copper-iron couple, and for the copper cast-iron couple over the range 0° to 200° C., appear to be of the order of 1° C., and were carefully verified by repeated and independent series of observations. The deviations of the platinum and platinum-rhodium 10 per cent. couple over the range 0° to 1000° C. are shown on a

smaller scale, and are seen to be of a similar nature, but rather greater in proportion. It should be observed that these deviations are continuous, and differ in character from the abrupt changes observed by Tait in special cases. A number of similar deviations at temperatures below 0° C. were found by the writer in reducing the curves representing the observations of Dewar and Fleming (*Phil. Mag.*, July 1895) to the normal scale of temperature from the platinum scale in which they are recorded. In many cases the deviations do not appear to favour any simple hypothesis as to the mode of variation of s with temperature, but as a rule the indication is that s is nearly constant, or even diminishes with rise of temperature. It may be interesting therefore to consider the effect of one or two other simple hypotheses with regard to the mode of variation of s with T.

§ 15. *Other Assumptions.*—If we take the analogy of a perfect gas and assume $s=s^\circ=$constant, we have

$$dE^2/dT^2=-s^\circ/T,\ dE/dT=s^\circ \log_e T^\circ/T \quad . \quad (12),$$

$$E_{(T-T')}=s^\circ T \log_e T^\circ/T - s^\circ T' \log_e T^\circ/T' \quad . \quad (13),$$

where T and T' are the temperatures of the junctions, and T° is the neutral temperature. These formulæ are not so simple and convenient as Tait's, though apparently founded on a more simple assumption, but they frequently represent the observations more closely. If we suppose that s is not quite constant, but increases or diminishes slightly with change of temperature according to a linear formula $s=s^\circ+2cT$ (in which s° represents the constant part of s, and c may have either sign), we obtain a more general formula which is evidently the sum of the two previous solutions and may be made to cover a greater variety of cases (see above, p. 291). Another simple and possible assumption is that made by Stansfield (*Phil. Mag.*, July 1898), that the value of s varies inversely as the absolute temperature. Putting $s=c/T$, we obtain

$$E_{(T-T')}=c \log_e T/T' - c(T-T')/T^\circ \quad . \quad . \quad (14),$$

which is equivalent to the form given by Stansfield, but with the neutral temperature T° explicitly included. According to this formula, the Peltier effect is a linear function of the temperature. It may appear at first sight astonishing that it should be possible to apply so many different assumptions to the solution of one and the same problem. In many cases a formula of the last type would be quite inapplicable, as Stansfield remarks, but the difference between the three is often much less than might be supposed. For instance, in the case of 10% Rh. Pt. – Pt. couple, if we calculate three formulæ of the above types to satisfy the same pair of observations at 0° – 445° and 0° – 1000° C., we shall find that the formula $s=$constant lies midway between that of Tait and that of Stansfield, but the difference between the formulæ is of the same order as that between different observers. In this particular case the parabolic formula appears to be undoubtedly inadequate. The writer's observations agree more nearly with the assumption $s=$ constant, those of Stansfield with $s=c/T$. Many other formulæ have been suggested. Holborn and Day (*Berl. Akad.*, 1899) have gone back to Tait's method at high temperatures, employing arcs of parabolas for limited ranges. But since the parabolic formula is certainly erroneous at low temperatures, it can hardly be trusted for extrapolation above 1000° C.

§ 16. *Absolute Measurement of Thomson Effect.*—Another method of verifying Tait's hypothesis, of greater difficulty but of considerable interest, is to measure the absolute value of the heat absorbed by the Thomson effect, and to observe whether or not it varies with the temperature. Le Roux (*Ann. Chim. Phys.*, x. p. 201, 1867) made a number of relative measurements of the

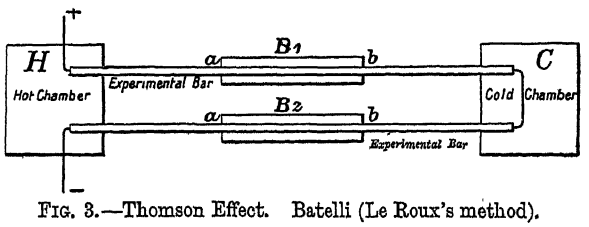

FIG. 3.—Thomson Effect. Batelli (Le Roux's method).

effect in different metals, which agreed qualitatively with observations of the thermoelectric power, and showed that the effect was proportional to the current for a given temperature gradient. Batelli has applied the same method (*Accad. Sci. Turin*, 1886) to the absolute measurement. He observed with a thermocouple the difference of temperature (about ·01° C.) produced by the Thomson effect in twenty minutes between two mercury calorimeters, B_1 and B_2, surrounding the central portions of a pair of rods arranged as in Le Roux's method (see Fig. 3). The value of the Thomson effect was calculated by multiplying this difference of temperature by the thermal capacity of either calorimeter, and dividing by the current, by the number of seconds in twenty minutes, and by twice the difference of temperature (about 20°) between the ends a and b of either calorimeter. The method appears to be open to the objection that the difference of temperature reached in so long an interval would be more or less independent of the thermal capacities of the calorimeters, and would also be difficult to measure accurately with a thermocouple under the conditions described. The general results of the work appeared to support Tait's hypothesis that the effect was proportional to the absolute temperature, but direct thermoelectric tests do not appear to have been made on the specimens employed, which would have afforded a valuable confirmation by the comparison of the values of d^2E/dT^2, as in Jahn's experiments.

§ 17. *King's Experiments.*—The method employed by the writer, to which allusion has already been made, consisted in observing the change of distribution of temperature in terms of the resistance along a wire heated by an electric current, when the heating current was reversed. It has been fully described by King (*Proc. Amer. Acad.*, June 1898), who applied it most successfully to the case of copper. Although the effect in copper is so small, he succeeded in obtaining changes of temperature due to the Thomson effect of the order of 1° C., which could be measured with satisfactory accuracy. He also determined the effect of change of

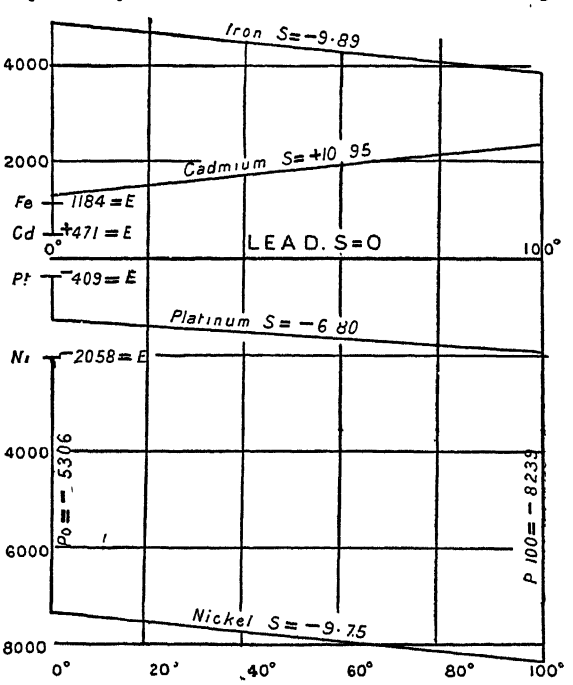

FIG. 4.—Potential Diagrams of Thermocouple on the Contact Theory.

temperature distribution on the rate of generation of heat by the current, and on the external loss of heat by radiation, convection, and conduction. It is necessary to take all these conditions carefully into account in calculating the balance due to the Thomson effect. According to King's experiments, the value of the effect appears to diminish with rise of temperature to a slight extent in copper, but the diminution is so small that he does not regard it as established with certainty. The value found at a temperature of 150° C. was +2·5 microjoules per ampere-second per degree, or +2·5 microvolts per degree in the case of copper, which agrees very fairly with the value deduced from thermoelectric tests. The value found by Batelli for iron was −5·0 microvolts per degree at 108° C., which appears too small in comparison. These measurements, though subject to some uncertainty on account of the great experimental difficulties, are a very valuable confirmation of the accuracy of Thomson's theory, because they show that the magnitude of the effect is of the required order, but they cannot be said to be strongly in support of Tait's hypothesis. A comparison of the results of different observers would also suggest that the law of variation may be different in different metals, although the differences in the values of d^2E/dT^2 may be due in part to differences of purity or errors of observation. It would appear, for instance, according to the observations of Dewar and Fleming, that the value of s for iron is positive below −150° C., at which point it vanishes. At ordinary temperatures the value is negative, increasing rapidly in the negative direction as the temperature rises. This might be appropriately represented, as already suggested, by a linear formula $s=s^\circ-cT$.

§ 18. *Potential Diagrams on the Contact Theory.*—It is instructive to consider the distribution of potential in a thermoelectric

circuit, and its relation to the resultant E.M.F. and to the seat of the E.M.F. In Fig. 4, which is given as an illustration, the cold junctions are supposed to be at 0° C. and the hot junctions at 100° C. Noll's values (Table I.) are taken for the E.M.F., and it is supposed that the coefficient of the Thomson effect is zero in lead, *i.e.* that there is no E.M.F. and that the potential is uniform throughout the length of the lead wire. Taking the lead-iron couple as an example, the value of dE/dt at the hot junction 100° C. is 10·305 microvolts per degree, and the value of the Peltier coefficient $P = TdE/dT$ is +3844 microvolts. In other words, we may suppose that there is an E.M.F. of that magnitude situated at the junction which causes positive electricity to flow from the lead to the iron. If the circuit is open, as represented in the diagram, the flow will cease as soon as it has raised the potential of the iron 3844 microvolts above that of the lead. In the substance of the iron itself there is an E.M.F. due to the Thomson effect of about 10 microvolts per degree tending to drive positive electricity from hot to cold, and raising the cold end of the iron 989 microvolts in potential above the hot end on open circuit. At the cold junction the iron is supposed to be connected to a piece of lead at 0° C., and there is a sudden drop of potential due to the Peltier effect of 3648 microvolts. If the circuit is cut at this point, there remains a difference of potential $E = 1184$ microvolts, the resultant E.M.F. of the circuit, tending to drive positive electricity from the iron to the lead across the cold junction. If the circuit is closed, there will be a current $C = E/R$, where $R = R' + R''$, the sum of the resistances of the lead and iron. The flow of the current will produce a fall of potential ER'/R in the lead from cold to hot, and ER''/R in the iron from hot to cold, but the potential difference due to the Peltier effect at either junction will not be affected. For simplicity in the diagram the temperature gradient has been taken as uniform, and the specific heat s = constant, but the total P.D. would be the same whatever the gradient.

Similar diagrams are given in Fig. 4 for cadmium in which both the specific heat and the Peltier effect are positive, and also for platinum and nickel in which both coefficients are negative. The metals are supposed to be all joined together at the hot junction, and the circuit cut in the lead near the cold junction. The diagram will serve for any selected couple, such as iron-nickel, and is not restricted to combinations with lead. The following table shows the component parts of the E.M.F. in each case :—

TABLE III.

Thermocouple.	P_{100}	$-P_0$	$-100\times s_{50}$	E_{0-100}
Iron-lead . .	+3844	+3648	−988	+1184
Cadmium-lead .	+2389	+823	+1095	+471
Platinum-lead .	−1919	−828	−682	−409
Nickel-lead . .	−8239	−5206	−975	−2058

The components for any other combination of two are found by taking the algebraic difference of the values with respect to lead.

§ 19. *Relation to the Volta Effect.*—It is now generally conceded that the relatively large differences of potential observable with an electrometer between metals on open circuit, as discovered by Volta, are due to the *chemical* affinities of the metals, and have no direct relation to thermoelectric phenomena or to the Peltier effect. The order of the metals in respect of the two effects is quite different. The potential difference, due to the Volta effect in air, has been shown by Thomson (Lord Kelvin) and his pupils to be of the same order of magnitude, if not absolutely the same, as that produced in a dilute electrolyte in which two metallically-connected plates (*e.g.*, zinc and copper) are immersed. (On this hypothesis, it may be explained by regarding the air as an electrolyte of infinite specific resistance.) It is also profoundly modified by the state of the exposed surfaces, a coating of oxide on the copper greatly increasing the effect, as it would in a voltaic cell. The Peltier effect and the thermo-E.M.F., on the other hand, do not depend on the state of the surfaces, but only on the state of the substance. An attempt has been made to explain the Volta effect as due to the affinity of the metals *for each other*, but that would not account for the variation of the effect with the state of the surface, except as affecting the actual surface of contact. It is equally evident that chemical affinity between the metals cannot be the explanation of the Peltier E.M.F. This would necessitate chemical action at the junction when a current passed through it, as in an electrolytic cell, whereas the action appears to be purely thermal, and leads to a consistent theory on that hypothesis. The chemical action between metals in the solid state must be infinitesimal, and could only suffice to produce small charges analogous to those of frictional electricity; it could not maintain a permanent difference of potential at a metallic junction through which a current was passing. Although it is possible that differences of potential larger than the Peltier effect might exist between two metals in contact on open circuit, it is certain that the only effective E.M.F. in practice is the Peltier effect, and that the difference of potential in the substance of the metals when the circuit is complete cannot be greater than the coefficient P. The Peltier effect, it may be objected, measures that part only of the potential difference which depends upon temperature, and can therefore give no information about the absolute potential difference. But the reason for concluding that there is no other effective source of potential difference at the junction besides the Peltier effect, is simply that no other appreciable action takes place at the junction when a current passes except the Peltier generation or absorption of heat.

§ 20. *Convection Theory.*—The idea of convection of heat by an electric current and the phrase "specific heat of electricity" were introduced by Thomson as a convenient mode of expressing the phenomena of the Thomson effect. He did not intend to imply that electricity really possessed a positive or negative specific heat, but merely that a quantity of heat was absorbed in a metal when unit quantity of electricity flowed from cold to hot through a difference of temperature of 1°. The absorption of heat was considered as representing an equivalent conversion of heat energy into electrical energy in the element. The element might thus be regarded as the seat of an E.M.F., $dE = sdT$, where dT is the difference of temperature between its ends. The potential diagrams already given have been drawn on this assumption, that the Thomson effect is not really due to convection of heat by the current, but is the measure of an E.M.F. located in the substance of the conductor. This view with regard to the seat of the E.M.F. has been generally taken by the majority of writers on the subject. It is not, however, necessarily implied in the reasoning or in the equations given by Thomson, which are not founded on any assumptions with regard to the seat of the E.M.F., but only on the balance of heat absorbed and evolved in all the different parts of the circuit. In fact, the equations themselves are open to an entirely different interpretation in this respect from that which is generally given.

Returning again to the equations already given in § 11 for an elementary thermocouple, we have the following equivalent expressions for the E.M.F. dE, namely,

$$dE = dP + (s' - s'')dT = (P/T)dT = pdT = (p'' - p')dT,$$

in which the coefficient, P, of the Peltier effect, and the thermoelectric power, p, of the couple, may be expressed in terms of the difference of the thermoelectric powers, p' and p'', of the separate metals with respect to a neutral standard. So far as these equations are concerned, we might evidently regard the seat of the E.M.F. as located entirely in the conductors themselves, and not at all at the junctions, if p or $(p'' - p')$ is the difference of the E.M.F.s per degree in corresponding elements of the two metals. In this case, however, in order to account for the phenomenon of the Peltier effect at the junctions, it is necessary to suppose that there is a *real convection of heat* by an electric current, and that the coefficient P or pT is the difference of the quantities of heat carried by unit quantity of electricity in the two metals. On this hypothesis,

if we confine our attention to one of the two metals, say p'', in which the current is supposed to flow from hot to cold, we observe that $p''dT$ expresses the quantity of heat converted into electrical energy per unit of electricity by an E.M.F. p'' per 1° located in the element dT. It happens that the absolute magnitude of p'' cannot be experimentally determined, but this is immaterial, as we are only concerned with differences. The quantity of heat liberated by convection as the current flows from hot to cold is represented in the equation by $dP = d(pT)$. Since $d(p''T) = p''dT + Tdp''$, it is clear that the balance of heat liberated in the element is only $Tdp'' = s''dT$, namely, the Thomson effect, and is *not* the equivalent of the E.M.F. $p''dT$, because on this theory the absorption of heat is masked by the convection. If p is constant there is no Thomson effect, but it does not follow that there is no E.M.F. located in the element. The Peltier effect, on the other hand, may be ascribed entirely to convection. The quantity of heat $p''T$ is brought up to one side of the junction per unit of electricity, and the quantity of heat $p'T$ taken away on the other. The balance $(p'' - p')T$ is evolved at the junction. If, therefore, we are prepared to admit that an electric current can carry heat, the existence of the Peltier effect is no proof that a corresponding E.M.F. is located at the junction, or, in other words, that the conversion of heat into electrical energy occurs at this point of the circuit, or is due to the contact of dissimilar metals. On the contact theory, as generally adopted, the E.M.F. is due entirely to change of substance $(dP - Tdp)$; on the convection theory, it is due entirely to change of temperature (pdT). But the two expressions are equivalent, and give the same results.

§ 21. *Potential Diagrams on Convection Theory.*—The difference between the two theories is most readily appreciated by drawing the potential diagrams corresponding to the supposed locations of the E.M.F. in each case. The contact theory has been already illustrated in Fig. 4. Corresponding diagrams for the same metals on the convection theory are given in Fig. 5. In this

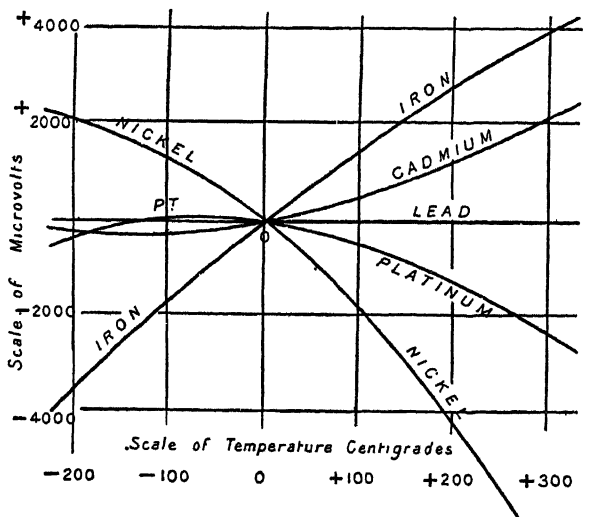

FIG. 5.—Curves of Thermo-E.M.F., or Potential Diagrams, on the Convection Theory.

diagram the metals are supposed to be all joined together and to be at the same time potential at the cold junction at 0° C. The ordinate of the curve at any temperature is the difference of potential between any point in the metal and a point in lead at the same temperature. Since there is no contact E.M.F. on this theory, the ordinates also represent the E.M.F. of a thermocouple metal-lead, in which one junction is at 0° C. and the other at t° C. For this reason the potential diagrams on the convection theory are more simple and useful than those on the contact theory. The curves of E.M.F. are in fact the most natural and most convenient method of recording the numerical data, more particularly in cases where they do not admit of being adequately represented by a formula. The line of lead is taken to be horizontal in the diagram, because the thermoelectric power, p, may be reckoned from any convenient zero. It is not intended to imply that there is no E.M.F. in the metal-lead with change of temperature, but that the value of p in this metal is nearly constant, as the Thomson effect is very small. It is very probable that the absolute values of p in different metals are of the same sign and of the same order of magnitude, being large compared with the differences observed. It would be theoretically possible to measure the absolute value in some metal by observing with an electrometer the P.D. between parts of the same metal at different temperatures, but the difference would probably be of the order of only one-hundredth of a volt for a difference of 100° C. It would be sufficiently difficult to detect so small a difference under the best conditions. The difficulty would be greatly increased, if not rendered practically insuperable, by the large difference of temperature.

§ 22. *Conduction Theory.*—In Thomson's theory it is expressly assumed that the reversible thermal effects may be considered separately without reference to conduction. In the conduction theory of Kohlrausch (*Pogg. Ann.*, 1875, vol. 156, p. 601), the fundamental postulate is that the thermo-E.M.F. is due to the conduction of heat in the metal, which is contrary to Thomson's theory. It is assumed that a flow of heat Q, due to conduction, tends to carry with it a proportional electric current $C = aQ$. This is interpreted to mean that there is an E.M.F. $dE = -akr\,dT = -\theta dT$, in each element, where k is the thermal conductivity and r the specific resistance. The "thermoelectric constant," θ, of Kohlrausch, is evidently the same as the thermoelectric power, p, in Thomson's theory. In order to explain the Peltier effect, Kohlrausch further assumes that an electric current, C, carries a heat-flow, $Q = A\theta C$, with it, where "A is a constant which can be made equal to unity by a proper choice of units." If A and θ are constant, the Peltier effects at the hot and cold junctions are equal and opposite, and may therefore be neglected. The combination of the two postulates leads to a complication. By the second postulate the flow of the current increases the heat-flow, and this by the first postulate increases the E.M.F., or the resistance, which therefore depends on the current. It is difficult to see how this complication can be avoided, unless the first postulate is abandoned, and the heat-flow due to conduction is assumed to be independent of the thermoelectric phenomena. By applying the first law of thermodynamics, Kohlrausch deduces that a quantity of heat, $C\theta dT$, is absorbed in the element dT per second by the current C. He wrongly identifies this with the Thomson effect, by omitting to allow for the heat carried. He does not make any application of the second law to the theory. If we apply Thomson's condition $P = TdE/dT = Tp$, we have $A = T$. If we also assume the ratio of the current to the heat-flow to be the same in both postulates, we have $a = 1/T\theta$, whence $\theta^2 = kr/T$. This condition has recently been applied by Liebenow (*Wied. Ann.*, 68, p. 316). It simplifies the theory, and gives a possible relation between the constants, but it does not appear to remove the complication above referred to, which seems to be inseparable from any conduction theory.

Boltzmann (*Sitz. Wien. Akad.*, 1887, vol. 96, p. 1258) gives a theoretical discussion of all possible forms of expression for thermo-electric phenomena. Neglecting conduction, all the expressions which he gives are equivalent to the equations of Thomson. Taking conduction into account in the application of the second law of thermodynamics, he proposes to substitute the inequality, $Td/dET - P \leqq 2\sqrt{T}(\sqrt{k'r'} + \sqrt{k''r''})$, instead of the equation given by Thomson, namely, $P = TdE/dT$. Since, however, Thomson's equation has been so closely verified by Jahn, it is probable that Boltzmann would now consider that the reversible effects might be treated independently of conduction.

§ 23. *Thermoelectric Relations.*—A number of suggestions have been made as to the possible relations between heat and electricity, and the mechanism by which an electric current might also be a carrier of heat. The simplest is probably that of Weber (*Wied. Ann.*, 1875), who regarded electricity as consisting of atoms much smaller than those of matter, and supposed that heat was the kinetic energy of these electric atoms. If we suppose that an electric current in a metal is a flow of negative electric atoms in one direction, the positive electricity associated with the far heavier material atoms remaining practically stationary, and if the atomic heat of electricity is of the same order as that of an equivalent quantity of hydrogen or any other element, the heat carried per ampere-second at 0° C., namely P, would be of the order of ·030 of a joule, which would be ample to account for all the observed effects on the convection theory. Others

have considered conduction in a metal to be analogous to electrolytic conduction, and the observed effects to be due to "migration of the ions." The majority of these theories are too vague to be profitably discussed in an article like the present, but there can be little doubt that the study of thermoelectricity affords one of the most promising roads to the discovery of the true relations between heat and electricity.

Alphabetical Index of Symbols.

a, b, c = Numerical constants in formulæ.
C = Electric Current.
E = E.M.F. = Electromotive Force.
k = Thermal Conductivity.
P = Coefficient of Peltier Effect.
$p = dE/dt$ = Thermoelectric Power.
Q = Heat-flow due to Conduction.
R = Electrical Resistance; r, Specific Resistance.
s = Specific Heat, or Coefficient of Thomson Effect.
t = Temperature on the Centigrade Scale.
T = Temperature on the Absolute Scale.

(H. L. C.)

Thermometry; Pyrometry.—A Pyrometer is an instrument specially designed for measuring high temperatures, and differs from a thermometer in details of construction only, and not in principle, so that the two subjects may be most advantageously treated together. The theoretical principles underlying the science of thermometry have been ably expounded by Lord Kelvin in the article HEAT (*Ency. Brit.*, vol. xi. p. 554). The most important varieties of thermometer in common use have also been described in the articles THERMOMETER (*Ency. Brit.*, vol. xxiii. p. 288) and PYROMETER (*Ency. Brit.*, vol. xx. p. 129). The object of the present article is to describe and explain the advances which have been made in the practice of scientific thermometry or "thermometry of precision," and in the practical application of electrical methods to the accurate measurement of temperature, during the last twenty years of the 19th century.

§ 1. *Temperature.*—The idea of temperature or degree of hotness is a primary conception derived directly from our sensations of heat and cold, and in part from those of light and colour. For ordinary temperatures the sense of touch serves as a rough thermometer, for high temperatures the sense of sight as a rough pyrometer. The idea of temperature therefore requires no explanation or definition. It is very often explained as "the condition of a body considered with reference to its power of communicating heat to other bodies." Similarly difference of temperature is often defined in terms of the flow of heat. Such definitions are somewhat unsatisfactory, because the "flow of heat" is really a secondary conception derived from observations of changes of state and temperature. In considering the measurement of temperature it is necessary, however, to define the scale or system on which it is to be measured.

§ 2. *Zero: Fundamental Interval.*—In all systems of measuring temperature it is necessary (1) to choose a zero or starting-point from which to reckon, (2) to determine the size of the degree by subdividing the interval between two selected fixed points of the scale (called the "fundamental interval") into a given number of equal parts. In all systems of measurement, the fundamental interval selected is that between the temperature of melting ice and the temperature of condensing steam, under standard atmospheric pressure. On the Centigrade system, which alone need be considered here, the fundamental interval is divided into 100 parts, and the melting-point of ice is taken as the zero of the scale. We shall denote temperature reckoned on this system by the letter t, or by affixing the letter C. It is often convenient to reckon temperature, not from the melting-point of ice, but from a theoretical or absolute zero representing the lowest conceivable temperature. We shall denote temperature reckoned in this manner by the letter T, or θ, or by affixing the letters *Abs.* In practice, since the absolute zero is unattainable, the absolute temperature is deduced from the Centigrade temperature by adding a constant quantity, T_0, representing the interval between the absolute zero and the melting-point of ice; thus $T = t + T_0$.

§ 3. *Arbitrary Scales.*—An arbitrary scale can be constructed by selecting any physical property of a substance which varies regularly with the temperature, such as the volume of a liquid, or the pressure or density of a gas, or the electrical resistance of a metal. Thus if V denote the volume of a given mass at the temperature t, and if V_0, V_1 represent the volumes of the same mass at the temperatures 0° and 100° C., the size of 1° C. on the scale of this arbitrary thermometer is one hundredth part of the fundamental interval, namely $(V_1 - V_0)/100$, and the temperature t at volume V is the number of these degrees contained in the expansion $V - V_0$ between 0° and t° C. We thus arrive at the formula

$$t = 100\,(V - V_0)/(V_1 - V_0) \quad . \quad . \quad . \quad (1),$$

which is the general expression for the temperature Centigrade on any such arbitrary scale, provided that we substitute for V the particular physical property selected as the basis of the scale. If we prefer to reckon temperature from an arbitrary zero defined by the vanishing of V, which may conveniently be called the *fundamental zero* of the scale considered, we have, putting $V = 0$ in equation (1), the numerical values of the fundamental zero T_0, and of the temperature T reckoned from this zero

$$T_0 = 100\,V_0/(V_1 - V_0), \text{ and } T = T_0 V/V_0 = t + T_0 \quad . \quad (2).$$

It is frequently convenient to measure temperature in this manner when dealing with gases, or electrical resistance thermometers.

§ 4. *Thermodynamical Scale.*—It is possible, by reference to the principles of thermodynamics, to construct scales of temperature which shall be "absolute" in the sense of being independent of the properties of any material substance. The thermodynamical scale generally selected is that defined by Lord Kelvin in such a manner as to coincide as closely as possible with the scale of the gas-thermometer. His definition (*Proc. R. S. Ed.*, 1854) is as follows (see also THERMODYNAMICS, § 4): "The ratio of any two temperatures on the thermodynamical scale is the ratio of the quantity of heat taken in at the higher temperature to the quantity of heat rejected at the lower temperature by a perfectly reversible thermodynamical engine working with a source and refrigerator at the temperatures considered." If, when the engine is working between the temperatures θ_0 and θ_1 corresponding to 0° and 100° C. respectively on the thermodynamical scale, a quantity of heat H_1 is taken in at θ_1 for each quantity H_0 rejected at θ_0, and if the fundamental interval is divided into 100 degrees, we have for the numerical values of the temperature of the melting-point of ice θ_0 on the thermodynamic scale, and of the temperature θ reckoned from the absolute zero,

$$\theta_0 = 100\,H_0/(H_1 - H_0), \text{ and } \theta = \theta_0 H/H_0 = t + \theta_0, \quad . \quad (3)$$

where H is the quantity of heat taken in at θ for each quantity H_0 rejected at θ_0. This scale can be most nearly realized in practice by observing the temperature T on the scale of a gas-thermometer, and making special experiments on the gas to determine how far its scale deviates from that of the thermodynamical engine. In the case of the gases hydrogen and helium, which can exist in the liquid state only at very low temperatures, the deviations from the thermodynamical scale at ordinary temperatures

are so small that they cannot be certainly determined. Thermometers containing these gases are generally taken as the ultimate standards of reference in practical thermometry.

Mercurial Thermometry.

§ 5. The most familiar type of thermometer depends on the apparent expansion of a liquid hermetically sealed in a glass bulb attached to a graduated stem of fine bore. Of all liquid-in-glass thermometers that containing mercury is almost invariably selected for scientific purposes, although at first sight mercury would appear to be the least suitable liquid, on account of its small coefficient of expansion. The smallness of the expansion necessitates an extremely fine bore for the stem, which introduces errors in consequence of the high surface tension of mercury. The considerable density of the liquid also tends to exaggerate the effects of change of position due to variation of the pressure exerted on the interior of the bulb by the liquid column. These errors are small and fairly regular, and can be corrected within certain limits. A much more serious source of trouble, especially at high temperatures, is the imperfect elasticity of the glass, which causes more or less irregular changes in the volume of the bulb. The effect of these changes on the readings of the thermometer is enhanced by the smallness of the expansion of mercury, and might be reduced by employing a more expansible liquid. It is more likely, however, that the defect will be remedied in the near future by the construction of thermometers of fused silica (SiO_2), which is the most perfectly elastic solid hitherto discovered. For work at low temperatures the range of a mercury thermometer is limited by its freezing-point (−39° C.). These are the serious disadvantages attending the use of mercury, but in other respects it possesses so many advantages over alcohol or other substitutes, that it will in all probability continue to be used almost exclusively in thermometers of this type for scientific work. Among its chief advantages may be reckoned its high boiling-point (357° C.), and the absence of evaporation from the top of the thread, which is so serious a source of error with the alcohol thermometer. With mercury the evaporation is almost inappreciable at 100° C., and can in all cases be avoided by exposing the upper parts of the emergent thread to the temperature of the air. Although an evacuated mercury thermometer cannot be safely used at temperatures over 300° C., owing to the breaking up of the thread of liquid in the stem, it has been found possible, by filling the upper part of the stem with nitrogen or carbonic acid gas under high pressure, to extend the range to 550° C. A more important advantage for accurate work is the fact that mercury does not wet glass, and avoids any possible errors due to adherent films of liquid on the walls of the tube. This greatly facilitates observations, and also renders it possible to "calibrate" the thermometer *after* construction, which cannot be satisfactorily accomplished with other liquids. The process of construction and calibration is further facilitated by the fact that mercury does not dissolve air to any appreciable extent. In consequence of the regularity of expansion of mercury at ordinary temperatures, the scale of the mercury thermometer agrees very closely with that of the gas thermometer. The liquid is very easily obtained in a high state of purity by distillation, and has practically no chemical action on glass. In this respect it is superior to the liquid alloy of potassium and sodium, which rapidly reduces silica at high temperatures. The high conductivity and low specific heat of mercury as compared with most other liquids tend to render the thermometer quick and sensitive in action. Its opacity considerably facilitates accurate reading, and even the smallness of its expansion has one great countervailing advantage, in that the correction for stem-exposure is proportionately reduced. This correction, which (even in the case of mercury) may amount to as much as 40° C. at 550° C., is far the most uncertain in its application, and is the most serious objection to the use of the liquid-in-glass thermometer at high temperatures.

§ 6. *Construction.* — The construction of the most accurate type of mercury thermometer has undergone some changes of detail in recent years. The range of the most accurate standards is generally restricted to the fundamental interval. The length of a degree on the stem can be increased to any extent by enlarging the bulb or diminishing the bore of the stem, but it is found in practice that there is no advantage in making the scale more open than one centimetre to the degree C. in standard instruments, or in increasing the number of divisions beyond ten or at most twenty to the degree. Enlarging the bulb makes the instrument sluggish, and exaggerates the errors due to imperfect elasticity. Diminishing the bore of the tube increases the errors due to capillary friction. Even one centimetre to the degree is an impracticable scale for thermometers graduated continuously from 0° to 100° C., owing to the excessive length of the stem. In order to secure so open a scale, it is necessary to limit the range to 35°, or at most 50°. The fixed points 0° and 100° may still be retained, for purposes of testing and reference, by the device, now commonly employed, of blowing auxiliary bulbs or "*ampoules*" on the stem, the volume of which is carefully adjusted to correspond with the number of degrees that it is desired to suppress. In the best instruments the bulb is not blown on the capillary tube itself, but is formed of a separate piece of tube fused on to the stem. It is possible in this manner to secure greater uniformity of strength and regularity of dimensions. The thickness of the glass is generally between half a millimetre and one millimetre. The advantage in point of quickness gained by making the glass thin is more than counterbalanced by increased fragility and liability to distortion. The best form of bulb is cylindrical, of the same external diameter as the stem. The bore of the stem should also be cylindrical, and not oval or flattened, in order to diminish errors due to capillarity, and to secure the greatest possible uniformity of section. The glass should be clear, and not backed with opal, both to admit of reading from either side, and to minimize risk of bending or distortion. In the commoner sorts of thermometers, which are intended for rough purposes and to be read without the application of minute corrections, it is not unusual to divide the tube into divisions of equal volume by a preliminary calibration. In the most accurate instruments it is preferable to divide the tube into divisions of equal length, as this can be more accurately effected. The corrections to be applied to the readings to allow for inequalities of bore can be most satisfactorily determined in the case of mercury thermometers by calibrating the tube after the instrument is completed (see Calibration, vol. xxvi.). This correction is known as the "calibration correction." Instead of being separately determined, it may be included in the scale correction by comparison with a standard instrument, such as a platinum-resistance thermometer.

§ 7. *Corrections.*—The corrections to be applied to the readings of a mercury thermometer, in addition to the calibration correction, may be summarized under the following heads: (i.) Zero. (ii.) Fundamental Interval. (iii.) Internal and External Pressure. (iv.) Stem Exposure. (v.) Scale Correction, including Poggendorf's correction.

(I) The *changes of zero* are of two kinds. (*a*) *Secular rise* of zero due to gradual recovery from changes or strains acquired by the bulb during the process of manufacture. This process may be hastened and subsequent changes practically eliminated by annealing the bulb after manufacture, and before final adjustment, at a high temperature, such as that of boiling sulphur. A thermometer which has not been so treated may show a rise of zero amounting to as much as 20° or 30° when exposed for some time to a temperature of 350° C. (*b*) *Temporary depression* of zero after each exposure to a high temperature, followed by a slow recovery which may last for days or weeks. The best thermometers of hard glass show a depression of zero amounting to about one-tenth of 1° C. after exposure to 100° C. In softer glass the depression is usually greater and more persistent, and may amount to half a degree after 100° C. At higher temperatures the depression generally increases roughly as the square of the temperature above 0° C. It may amount to 2° or 3° at 300° C. The effect cannot be calculated or predicted in any series of observations, because it depends in so complicated a manner on the past history and on the time. It is a most serious difficulty in accurate mercurial thermometry, especially at high temperatures. The most satisfactory method of correction appears to be to observe the zero *immediately after each reading*, and to reckon the temperature from the variable zero thus observed. The rationale of this procedure is that the depression is produced at the high temperature much more rapidly than the subsequent recovery at the low temperature. The thermometer is taken from the bath and allowed to cool rapidly by free exposure to the air. As soon as it reaches 40° or 50° C., it is plunged in the melting ice, and the lowest point reached is taken as the temporary zero.

The following formulæ have been proposed by various observers to represent the depression of zero for different kinds of glass :—

Pernet, French *cristal*, $dz = 0{\cdot}0040(t/100)^2$ . . .
Guillaume, *Verre dur*, 0 – 100° C., $dz = (8886t + 10{\cdot}84t^2)\,10^{-7}$
,, *Cristal dur*, 0 – 190° C., $dz = (7970t + 329t^2)10^{-7}$ } (4).
Bottcher, Jena, 16, iii., $dz = ((7100t - 8t^2)\,10^{-7}$ . .

The symbol dz in these formulæ stands for the depression of zero produced by an exposure to a temperature t. The depression is about three times as large in French crystal as in English flint glass, and varies roughly as the square of t. *Verre dur* and Jena, 16, iii., are varieties of hard glass chosen as standards in France and Germany respectively, on account of the comparatively small depression of zero to which they are liable. At low temperatures, up to 50° C., the depression is very nearly proportional to t, but at temperatures above 100° C. it is necessary to adopt another formula in which the term depending upon t^2 is more important. These formulæ are useful as giving an idea of the probable size of the correction in any case, but they cannot be employed in practice except in the simplest cases and at low temperatures. On account of these temporary changes of zero, a mercury thermometer intended for the most accurate work at ordinary temperatures (as in calorimetry) should preferably never be heated above 40° or 50° C., and certainly never above 100° C. Above 100° C. the changes of zero become more irregular and more variable, depending on the rate of cooling and on the sequence of previous observations, so that even if the method of observing the zero after each reading is adopted, the order of precision attainable rapidly diminishes.

(II) *Fundamental Interval.*—The thermometer to be tested is exposed to steam condensing at atmospheric pressure in an apparatus which is often called a "hypsometer," constructed with double walls to protect the inner tube containing the thermometer from any cooling by radiation. The standard atmospheric pressure at which the temperature of the steam is by definition equal to 100° C. is equivalent to that produced by a column of mercury at 0° C. and 760 millimetres high, the force of gravitation being equal to that at sea-level in latitude 45°. The atmospheric pressure at the time of observation is reduced to these units by applying the usual corrections for temperature and gravitation. If the pressure is near 760 mm., the temperature of the steam may be deduced by assuming that it increases at the rate of 1° C. for 27·2 mm. of pressure. If the pressure is not near 760 mm., the application of the correction is less certain, but is generally taken from Regnault's tables, from which the following data are extracted. Thermometers cannot be satisfactorily tested at an elevated station where the height of the barometer H is less than 700 mm., as the steam point is too uncertain.

TABLE I.—*Temperature of Steam at pressures from* 790 *to* 710 *mm.*

Pressure (corrected) . .	790	780	770	760	750	740	730	720	710
Steam temp. = 100° C. + . .	+1·083	+·726	+·365	0	−·369	−·742	−1·120	−1·502	−1·888

Approximate formula $dt_1 = {\cdot}0367(H - 760) - {\cdot}000020(H - 760)^2$ . . . . . (5)

If the barometer has a brass scale correct at 0° C., and H be the reading in millimetres, the correction for temperature is made approximately by subtracting 0·00163 H mm.

If L is the latitude and M the height of the station in metres above the sea-level, the correction for gravitation is approximately made by subtracting $(0{\cdot}0026\ cos\ 2L + 0{\cdot}0000002M)\ H$ mm.

The zero of the thermometer is observed immediately after the steam point. If n be the interval in degrees of the scale between the two observations, and if t_1 be the temperature of the steam, the fundamental interval of the thermometer may be taken as $100\ n/t_1$, provided that t_1 is nearly 100° C. Since all the readings of a thermometer have to be corrected for the error of the fundamental interval, by dividing by the fundamental interval thus observed and multiplying by 100, it is a matter of some convenience in practice to have the instrument graduated so that the difference between the readings in ice and at 100° C. is very nearly 100° of the stem. The correction can then be applied as a small percentage independently of the other corrections. The method of determining the fundamental interval above described applies to all other kinds of thermometers, except that it is not generally necessary to observe the zero *after* the steam point. The temperature of the steam t_1 should be expressed in the scale of the thermometer tested, if the scale differs appreciably from that of Regnault.

(III) *Pressure Correction.*—The corrections for variations of internal and external pressure on the bulb are of some importance in accurate thermometry, but can be applied with considerable certainty at moderate temperatures. The correction for external pressure is assumed to be proportional to the change of pressure, and to be independent of the temperature. It is generally determined by enclosing the thermometer to be tested in a vessel of water, and observing the change of reading on exhausting or readmitting the air. The correction is generally between one and two thousandths of a degree per centimetre of mercury change of pressure, but must be determined for each thermometer, as it depends on the nature of the glass and on the form and thickness of the walls of the bulb. The coefficient of the correction for internal pressure is greater than that for external pressure by the difference between the compressibility of mercury and that of glass, and may be calculated from it by assuming this relation. If b_0, b_1, are the external and internal coefficients, expressed in degrees of temperature per centimetre of mercury, we have the relation

$b_1 = b_0 + 0{\cdot}00015$, degrees per cm. of mercury . . (6)

The coefficient of internal pressure can also be determined by taking readings in the horizontal and vertical positions when the thermometer is at some steady temperature such as that of ice or steam. The reading of the thermometer is generally reduced to an external pressure of one standard atmosphere, and to an internal pressure corresponding to the horizontal position. It is also possible to include the internal pressure correction in the scale correction, if the thermometer is always read in the vertical position. In addition to the variations of internal pressure due to the column of mercury in the stem, there are variations due to capillarity. The internal pressure is greater when the mercury is rising than when it is falling, and the reading is depressed to an extent depending on the fineness of the bore and the thinness of the walls of the bulb. The capillary pressure does not depend only on the bore of the tube, but also apparently to an even greater extent on the state of the walls of the tube. The least trace of dirt on the glass or on the mercury is capable of producing capillary pressures much greater than would be calculated from the diameter of the tube. Even in the best thermometers, when there are no inequalities of bore sufficient to account for the observed variations, it is seldom found that the mercury runs equally easily in all parts of the stem. These variations of capillary pressure are somewhat capricious, and set a limit to the order of accuracy attainable with the mercury thermometer. It appears that the difference of reading of a good thermometer between a rising and falling meniscus may amount to five or ten thousandths of a degree. The difference may be reduced by continuous tapping, but it is generally best to take readings always on a rising column, especially as the variations in the angle of contact, and therefore in the capillary pressure, appear to be much smaller for the rising meniscus. In ordinary work the zero reading and the steam reading would both generally correspond to a falling meniscus; the former necessarily, the latter on account of the phenomenon of the temporary depression of zero, which causes the thermometer to read higher during the first moments of its exposure to steam than it does when the expansion of the bulb has reached its limit. It is easy to secure a

rising meniscus at the steam point by momentarily cooling the thermometer. At the zero point the meniscus generally commences to rise after five or ten minutes. The question, however, is not of much importance, as the error, if any, is regular, and the correction for capillarity is necessarily uncertain.

(IV) *Stem-Exposure Correction.*—When the bulb of a mercury thermometer is immersed in a bath at a temperature t, and a part of the column of mercury having a length of n degrees is exposed to a lower temperature t_2, the reading of the thermometer will be lower by $a \times n \times (t - t_2)$ degrees (nearly) than it would have been if the whole of the mercury and stem had been at the temperature t. The factor a in this expression is the apparent coefficient of expansion of mercury in glass, and varies from ·000150 to ·000165 for different kinds of glass. In order to apply this correction, it is usual to observe t_2 by means of an auxiliary "stem-thermometer" with its bulb placed near the middle of the emergent column n. Occasionally stem-thermometers with long thin bulbs are employed to give more nearly the average temperature of the whole emergent column. Owing to conduction along the stem of the thermometer, and to heated vapours near the bath, the mean temperature determined in this manner is generally too low. To allow for this empirically, an arbitrary reduction is often made in the value taken for n or a, but this cannot be regarded as satisfactory for work of precision. The only practical method of reducing the correction is to limit the number of degrees n exposed, or, in other words, to work with thermometers of "limited range." Each of these thermometers must then be corrected by comparison with a standard thermometer free from stem-exposure correction, such as a platinum-resistance thermometer. To secure results of any value the correction must be determined at each point under the actual conditions of observation under which the thermometer is to be used. In work of precision it is necessary to use ten or twenty thermometers to cover a range of 300°, as this is the only method of securing an open scale and reasonable accuracy as regards stem-exposure. To quote the opinion of M. Guillaume, one of the leading authorities on mercurial thermometry: "When this correction is large, it cannot generally be determined with sufficient approximation for measurements of precision. The mercury thermometer should then be replaced by other instruments, among which those based on the variation of the electrical resistance of metals hold the first rank."

(V) *Scale Correction.*—The correction required to reduce the readings of a mercurial thermometer to the normal scale may appropriately be called the "scale correction." One of the chief advantages of the mercurial thermometer for scientific purposes is that its scale agrees very closely with the thermodynamical scale between 0° and 200° C. The scale corrections of the standard French thermometers of *verre dur* have been very carefully determined over the range 0° to 80° C. by M. Chappuis using a constant-volume gas thermometer containing hydrogen (at an initial pressure of one metre of mercury at 0° C.) as the representative of the normal scale. His observations between 0° and 80° C. are represented by the quartic equation

$$t_h - t_m = t(t-100)\,(-61{\cdot}859 + 0{\cdot}47351\,t - 0{\cdot}0011577\,t^2) \times 10^{-6}, \quad (7)$$

in which t_h and t_m represent temperature on the scales of the hydrogen and mercury thermometers respectively. The *verre dur* mercury thermometer reads 0·112° C. above the hydrogen thermometer at 40° C., where the difference of the scales is a maximum. The scale corrections of the Jena-glass thermometers, deduced by comparison with the French *verre dur*, appear to be practically of the same magnitude, but show differences of as much as 0·010° C. on either side of the mean. It may be questioned whether it is possible to construct mercury thermometers with scales agreeing more closely than this, owing to inevitable variations in the quality and treatment of the glass. According to Guillaume, the scale of a French *cristal* thermometer t_c differs from that of the standard *verre dur* t_m between 0° and 50° C., according to the cubic formula

$$t_c - t_m = t(100-t)(14{\cdot}126 - 0{\cdot}0311t) \times 10^{-6} \quad . \quad . \quad (8)$$

According to some unpublished observations made by the writer in 1893–94, the scale of an English flint-glass thermometer, tested by comparison with a platinum thermometer, does not differ from that of the constant-pressure air thermometer by more than one or two hundredths of a degree between 0° and 100° C. But for the comparison of the scales to be of any value, it would be necessary to study a large number of such thermometers. It is possible to obtain much more consistent results if the thermometers are not heated above 50° C.

The comparisons of the *verre dur* thermometers with the normal scale at the International Bureau at Paris have not as yet extended beyond 100° C. The most important observations on the mercury thermometer above these limits appear to be those of Regnault already given in a previous article (HEAT, *Ency. Brit.*, vol. xi. p. 554). The more recent observations of Crafts were confined to French thermometers of *cristal dur* (*Comptes Rendus*, vol. 95, p. 863, 1882). He finds the following deviations from the hydrogen scale:—

t_h	150°	170°	200°	230°	250°	280°	300°	330°
$t_h - t_m$	+·25	+·35	+·27	−·02	−·26	−·63	−1·21	−2·48

The correction changes sign at about 230° C., owing to the rapid increase in the expansion of mercury. Between 0° and 150° C. it would appear that the coefficient of expansion of glass increases more rapidly than that of mercury.

Poggendorf's Correction.—It should be observed that, since in the construction of a mercury thermometer the tube is divided or calibrated so as to read in divisions of equal volume when the whole of the tube is at one temperature, the degrees do not as a matter of fact correspond to equal increments of the apparent expansion of mercury. The scale does not therefore agree in practice with the theoretical formula (1) for the scale of the expansion of mercury, since the expansion is measured in a tube which itself is expanding. A similar argument applies to the method of the weight thermometer, in which the overflow is measured by weight. Even if the expansion of mercury and glass were both uniform, as measured on the thermodynamical scale, the scale of the mercury thermometer, as ordinarily calibrated, would not agree with the thermodynamical scale. The difference can be

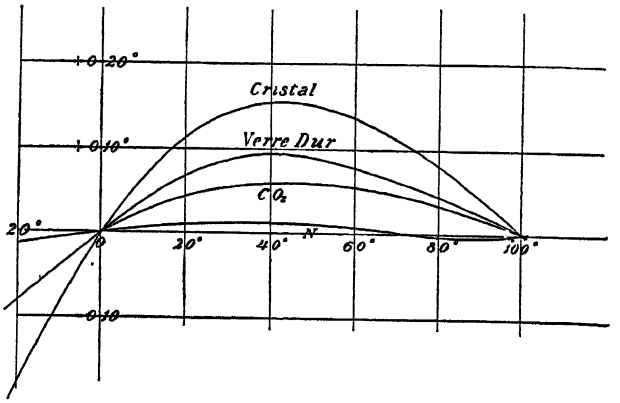

FIG. 1.—Differences between Scales of Mercury, and Gas Thermometers and Hydrogen Scale, according to Guillaume and Chappuis.

easily calculated if the actual expansion of mercury and glass is known. The correction is known as Poggendorf's, but is generally included in the scale correction, and is not applied separately. It has the effect of making the thermometer read higher at temperatures between 0° and 100° than it would if the divisions of the stem did not expand as the temperature rose. The amount of the correction for *verre dur* is given by Guillaume as

$$P.C. = t(100-t)(23{\cdot}920 + 0{\cdot}0240t) \times 10^{-6} \quad . \quad . \quad (9)$$

The value of this correction is between ·060° and ·080° at 50° C. for different thermometers.

GAS THERMOMETRY.

§ 8. The absolute or thermodynamical scale cannot be directly realized on account of the impossibility of constructing a perfectly reversible thermodynamic engine, and of the great practical difficulties involved in the accurate measurement of quantities of heat. It is necessary, therefore, to have recourse to indirect methods. Among the most interesting of these methods are the vapour-pressure thermometers described by Lord Kelvin (HEAT, vol. xi. p. 554). These instruments have the great advantage that the pressure is a function of the temperature only, and that no measurements of the volume of the space in which the thermometric substance is enclosed are required. The temperature scale of such an instrument depends only on the substance, and not on the material of the enclosure. From a practical point of view, however, the range of each instrument is too limited, and the scales differ too widely from uniformity. Although it is theoretically possible to deduce the absolute temperature from a study of the properties of

each vapour, it is practically impossible to carry out the required measurements, such as the determination of the specific volume of the saturated vapour, with sufficient accuracy to be of value for the realization of the absolute scale. On the other hand, the second method proposed by Lord Kelvin, and carried out experimentally with the assistance of Joule, for the reduction of the indications of the gas thermometer to the absolute scale, is in itself so delicate, and the deviations of the uncorrected gas thermometer from the absolute scale are so small, that this instrument is now universally regarded as the ultimate standard in thermometry. It had, in fact, already been adopted for this purpose by Regnault and others, on *à priori* considerations, before the absolute scale itself had been invented. Although the indications of a gas thermometer are not absolutely independent of the changes of volume of the envelope or bulb in which the gas is contained, the effect of any uncertainty in this respect is minimized by the relatively large expansibility of the gas. The capricious changes of volume of the bulb, which are so great a difficulty in mercurial thermometry, are twenty times less important in the case of the gas thermometer. As additional reasons for the choice we have the great simplicity of the laws of gases, and the approximate equality of expansion and close agreement of the thermometric scales of all gases, provided that they are above their critical temperatures. Subject to this condition, at moderate pressures and provided that they are not dissociated or decomposed, all gases satisfy approximately the laws of Boyle and Charles. These two laws are combined in the characteristic equation of the gaseous state, viz., $pv = RT$, in which p is the pressure and v the volume of unit mass of the gas in question, and R is a constant which varies inversely as the molecular weight of the gas, and is approximately equal to the difference of the specific heats. The equation in this form, without further restrictions, applies only to the ideal "perfect gas" which satisfies Boyle's law accurately, and in which the internal work of expansion is zero.

§ 9. *Practical Conditions.*—In practice it is not convenient to deal with unit mass, but with an arbitrary mass M occupying a space V, so that the specific volume $v = V/M$. It is also necessary to measure the pressure p in terms of mercury columns, and not in absolute units. The numerical value of the constant R is adjusted to suit these conditions, but is of no consequence in thermometry, as we are concerned with ratios and differences only. The equation may still be written in the form $T = pV/RM$, but in order to satisfy the essential condition that T shall be a definite function of the temperature in the case of a gas which does not satisfy Boyle's law exactly, it is necessary to limit the application of the equation to special cases which lead to definite, but not necessarily identical, thermometric scales. There are three special cases of practical importance, corresponding to three essentially distinct experimental methods.

(i.) *Volumetric Method* (constant-pressure).—In this method V is variable and p and M are constant. This method was employed by Gay-Lussac, and is typified in the ideal thermometer with reservoir of variable capacity designed by Lord Kelvin (*Ency. Brit.*, vol. xi. p. 575, Fig. 10). It corresponds to the method ordinarily employed in the common liquid-in-glass thermometer. It is not satisfactory in practice, owing to the difficulty of making a bulb of variable and measurable volume the whole of which can be exposed to the temperature to be measured.

(ii.) *Manometric Method* (constant-volume or density).—In this method p is variable and V and M are constant. Variations of temperature are observed and measured by observing the corresponding variations of pressure with a mercury manometer, keeping a constant mass, M, of gas enclosed in a volume, V, which is constant except for the unavoidable but small expansion of the material of which the bulb is made.

(iii.) *Gravimetric Method* (constant-pressure).—In this method M is variable and p and V are constant. This method is generally confounded with (i.) under the name of the constant-pressure method, but it really corresponds to the method of the weight thermometer, or the "overflow" method, and is quite distinct from an experimental standpoint, although it leads to the same thermometric scale. In applying this method, the weight M of the vapour itself may be measured, as in Regnault's mercury-vapour thermometer, or in Deville and Troost's iodine-vapour thermometer. The usual method of measuring the overflow is that of weighing mercury displaced by the gas. The mass of the overflow may also be estimated by observing its volume, or by water-displacement, but these methods are much less accurate.

In addition to the above, there are mixed methods in which both p and V or M are variable, such as those employed by Rudberg or Becquerel; but these are unsatisfactory for precision, as not leading to a sufficiently definite thermometric scale. There is also a variation of the constant-volume method (ii.), in which the pressure is measured by the volumetric compression of an equal mass of gas kept at a constant temperature, instead of by a manometer. This method is experimentally similar to (iii.), and gives the same equations, but a different thermometric scale to either (ii.) or (iii.). It will be considered with method (iii.), as the apparatus required is the same, and it is useful for testing the theory of the instrument. We shall consider in detail methods (ii.) and (iii.) only, as they are the most important for accurate work.

§ 10. *Construction of Apparatus.*—The manometric or constant-volume method was selected by Regnault as the standard, and has been most generally adopted since his time. His apparatus has not been materially modified except in points of detail. A description of his instrument will be found in most text-books on heat. The improvements introduced by M. Chappuis, of the International Bureau at Sèvres, in the construction of the constant-volume hydrogen thermometer selected by the committee for the determination of the normal scale, are also described in some recent text-books (*e.g.*, Watson's *Physics*). The most important is the combination of the manometer and the barometer into a single instrument with a single scale, thus materially reducing the number of readings required. The level of the mercury in the branch of the manometer communicating with the bulb of the gas thermometer is adjusted in the usual manner up to a fixed contact-point, so as to reduce the contained gas to a constant volume. Simultaneously the barometer branch of the manometer is adjusted so that the surface of the mercury makes contact with another point fixed in the upper end of the barometer tube. The distance between the two contact-points, giving the pressure of the gas in the thermometer, is deduced from the reading of a vernier fixed relatively to the upper contact-point. This method of reading the pressure is probably more accurate than the method of the cathetometer which is usually employed.

§ 11. *Pressure Correction.*—In the practical application of the manometric method there are certain corrections peculiar to the method, of which account must be taken in work of precision. The volume of the bulb is not accurately constant, but varies with change of pressure

and temperature. The thermal expansion of the bulb is common to all methods, and will be considered in detail later. The pressure correction is small, and is determined in the same manner as for a mercury thermometer. The value so determined, however, does not apply strictly except at the temperature to which it refers. If the pressure-coefficient were constant at all temperatures and equal to e, the pressure correction, dt, at any point t of the scale would be obtainable from the simple formula

$$dt = ep_0t(t-100)/T_0, \quad . \quad . \quad . \quad (10)$$

where p_0 is the initial pressure at the temperature T_0. But as the coefficient probably varies in an unknown manner, the correction is somewhat uncertain, especially at high temperatures. Another very necessary but somewhat troublesome correction is the reduction of the manometer readings to allow for the varying temperatures of the mercury and scale. Since it is generally impracticable to immerse the manometer in a liquid bath to secure certainty and uniformity of temperature, the temperature must be estimated from the readings of mercury thermometers suspended in mercury tubes or in the air near the manometer. It is therefore necessary to work in a room specially designed to secure great constancy of temperature, and to screen the manometer with the utmost care from the source of heat in measurements of high temperature. Regnault considered that the limit of accuracy of correction was one-tenth of a millimetre of mercury, but it is probably possible to measure to one-hundredth as a mean of several readings under the best conditions, at ordinary temperatures.

§ 12. *Stem-Exposure.*—In all gas thermometers it is necessary in practice that the part of the gas in contact with the mercury or other liquid in the manometer should not be heated, but kept at a nearly constant temperature. The space above the mercury, together with the exposed portion of the capillary tube connecting the manometer with the thermometric bulb, may be called the "dead space." If the volume of the dead space is kept as nearly as possible constant by adjusting the mercury always up to a fixed mark, the quantity of air in this space varies nearly in direct proportion to the pressure, *i.e.*, in proportion to the temperature of the thermometric bulb at constant volume. This necessitates the application of a stem-exposure correction, the value of which is approximately given by the formula

$$dt = rt(t-100)/T_2, \quad . \quad . \quad . \quad . \quad (11)$$

where r is the ratio of the volume of the dead space to the volume of the thermometric bulb, and T_2 is the mean temperature of the dead space, which is supposed to be constant. The magnitude of the correction is proportional to the ratio r, and increases very rapidly at high temperatures. If the dead space is 1 per cent. of the bulb, the correction will amount to only one-tenth of a degree at 50° C., but reaches 5° at 445° C., and 30° at 1000° C. It is for this reason important in high-temperature work to keep the dead space as small as possible and to know its volume accurately. With a mercury manometer, the volume is liable to a slight uncertainty on account of changes of shape in the meniscus, as it is necessary to use a wide tube in order to secure accurate measurements of pressure.

§ 13. *Compensation Method with Oil-Gauge.*—It is possible to avoid this difficulty, and to make the dead space very small, by employing oil or sulphuric acid or other non-volatile liquid to confine the gas in place of mercury (*Phil. Trans.*, A. 1887, p. 171). The employment of a liquid which wets the tube makes it possible to use a much smaller bore, and also greatly facilitates the reading of small changes of pressure. At the same time the instrument may be arranged so that the dead space correction is automatically eliminated with much greater accuracy than it can be calculated. This is effected as shown diagrammatically in Fig. 2, by placing side by side with the tube AB, connecting the bulb B to the manometer A, an exact duplicate CD, closed at the end D, and containing liquid in the limb C, which is of the same size as the branch A of the manometer and in direct communication with it. The tube CD, which is called the compensating tube, contains a constant mass of gas under exactly similar conditions of volume and temperature to the tube AB. If therefore the level of the liquid is always adjusted to be the same in both tubes AB and CD, the mass of gas contained in the dead space AB will also be constant, and is automatically eliminated from the equations, as they contain differences only.

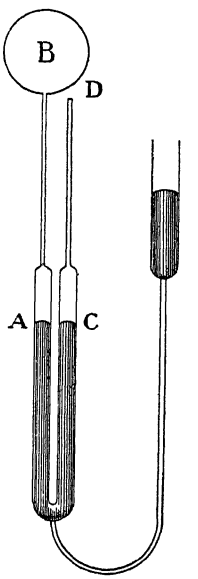

FIG. 2.—Method of Compensation.

§ 14. *Gravimetric Method.*—In the writer's opinion, the gravimetric or overflow method, although it has seldom been adopted, and is not generally regarded as the most accurate, is much to be preferred to the manometric method, especially for work at high temperatures. It is free from the uncertain corrections above enumerated as being peculiar to the manometric method. The apparatus is much simpler to manipulate and less costly to construct. If the pressure is kept constant and equal to the external atmospheric pressure, there is no strain of the bulb, which is particularly important at high temperatures. There is no dead space correction so long as the temperature of the dead space is kept constant. The troublesome operation of reading and adjusting the mercury columns of the manometer is replaced by the simpler and more accurate operation of weighing the mercury displaced, which can be performed at leisure. The uncertain correction for the temperature of the mercury in the manometer is entirely avoided. The reasons which led Regnault to prefer the constant-volume thermometer are frequently quoted, and are generally accepted as entirely conclusive, but it is very easy to construct the constant-pressure or gravimetric instrument in such a manner as to escape the objections which he urges against it. Briefly stated, his objections are as follows: (1) Any error in the observation of the temperature of the gas in the overflow space produces a considerable error in the temperature deduced, when the volume of the overflow is large. This source of error is very simply avoided by keeping the whole of the overflow in melting ice, an expedient which also considerably simplifies the equations. It happened that Regnault's form of thermometer could not be treated in this manner, because he had to observe the level of the mercury in order to measure the pressure. It is much better, however, to use a separate gauge, containing oil or sulphuric acid, for this purpose. The use of ice also eliminates the correction for the variation of density of the mercury by which the overflow is measured. (2) Regnault's second objection was that an error in the measurement of the pressure, or in reading the barometer, was more serious at high temperatures in the case of the constant-pressure thermometer than in the constant-volume method. Owing to the incessant variations in the pressure of the atmosphere, and in the temperature of the mercury columns, he did not feel able to rely on the

pressure readings (depending on observations of four mercury surfaces with the cathetometer) to less than a tenth of a millimetre of mercury, which experience showed to be about the limit of accuracy of his observations. This would be equivalent to an error of 0·036° with the constant-volume thermometer at any point of the scale, but with the constant-pressure thermometer the error would be larger at higher temperatures, since the pressure does not increase in proportion to the temperature. This objection is really unsound, because *the proportionate error* dT/T, or the error considered as a fraction of the whole temperature, remains constant at constant pressure, for a given constant error in the pressure. This is the ideal condition to be aimed at. That the proportionate error diminishes with rise of temperature, in the case of the constant-volume thermometer, is really of no advantage, because we can never hope to be able to measure high temperatures with greater proportionate accuracy than ordinary temperatures. The great increase of pressure at high temperatures in the manometric method is really a serious disadvantage, because it becomes necessary to work with much lower initial pressures, which implies inferior accuracy at ordinary temperatures and in the determination of the initial pressure and the fundamental interval.

§ 15. *Compensated Differential Gas Thermometer.*—The chief advantage of the gravimetric method, which Regnault and others appear to have missed, is that it is possible to make the measurements altogether independent of the atmospheric pressure and of the observation of mercury columns. This is accomplished by using, as a standard of constant pressure, a bulb containing a constant mass of gas in melting ice, side by side with the bulb in which the volume of the overflow is measured. The pressure in the thermometric bulb is adjusted to equality with the standard by means of a delicate oil-gauge of small bore, in which the difference of pressure is observed by means of a cathetometer microscope. This kind of gauge permits the rapid observation of small changes of pressure, and is far more accurate and delicate than the mercury manometer. The fundamental measurement of the volume of the overflow in terms of the weight of mercury displaced at 0° C. involves a single weighing made at leisure, and requires no temperature correction. The accuracy obtainable at ordinary temperatures in this measurement is about ten times as great as that attainable under the best conditions with the mercury manometer. At higher temperatures the relative accuracy diminishes in proportion to the absolute temperature, or the error dt increases according to the formula

$$dt/t = -(T/T_0)\, dw/w, \quad . \quad . \quad . \quad (12)$$

where w is the weight of the overflow and dw the error. This diminution of the sensitiveness of the method at high temperatures is commonly urged as a serious objection to the method, but the objection is really without weight in practice, as the possible accuracy of measurement is limited by other conditions. So far as the weighing alone is concerned, the method is sensitive to one-hundredth of a degree at 1000° C., which is far beyond the order of accuracy attainable in the application of the other corrections.

§ 16. *Description of Practical Form of Instrument.*—A form of gas thermometer constructed on the principles above laid down, with the addition of a duplicate set of connecting tubes for the elimination of the stem-exposure correction by the method of automatic compensation already explained, is shown in Fig. 3. This type of instrument, designed for work of the highest precision, was described and exhibited at a meeting of the Royal Society in December 1891 (*Proc. R. S.*, vol. 50, p. 243), but has not hitherto been figured in any publication, except in a diagrammatic form (*e.g.*, Preston's *Heat*, p. 133). The connexions of the various parts of the instrument will be better understood by reference to the diagram (Fig. 4), in which the two sides of the instrument are separated. The connecting tubes to the thermometric bulb T are compensated by a similar pair of tubes C, which are shown in the diagram on the extreme right, but are really in close proximity to the thermometric bulb. The taps t_1 t_2 serve for cleaning and drying the apparatus, and for the introduction and removal of mercury when the bulb T is used as a weight thermometer for determining the expansion of the glass. The thermometric bulb T is connected to the "overflow" bulb M, in which the expansion is measured by the displacement of mercury. The system of tubes and taps connected to the overflow bulb serves for the introduction or removal of weighed quantities of mercury. The standard pressure-bulb S is an exactly similar bulb to the overflow bulb, and is provided with an exactly similar set of connexions. It is placed side by side with the overflow bulb in a large vessel of ice. Between the two bulbs is the oil-gauge G, in which the difference pressure is observed by a cathetometer microscope. An auxiliary mercury-gauge N is added to show when the difference of pressure is small enough to be within the range of the oil-gauge.

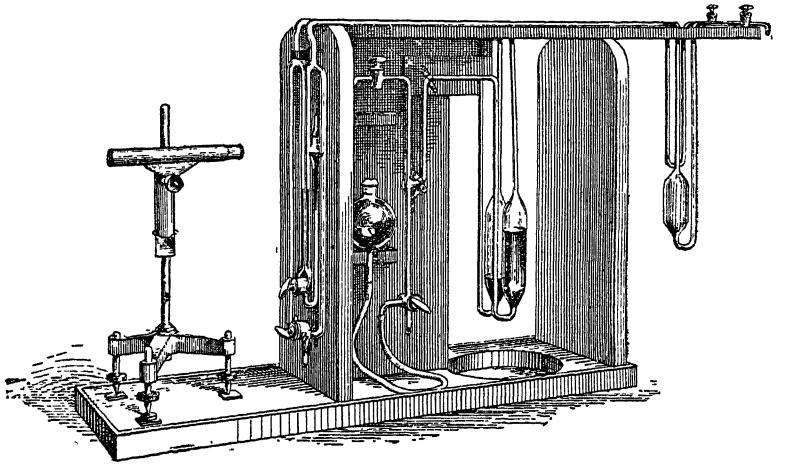

FIG. 3.—Compensated Differential Gas Thermometer.

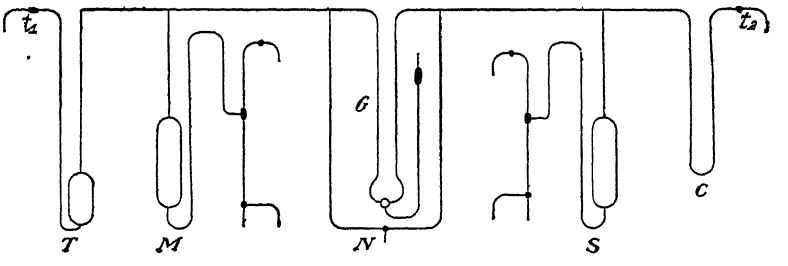

FIG. 4.—Diagram of Compensated Differential Gas Thermometer.

In setting up the instrument, after cleaning and drying and calibrating the bulbs and connecting tubes, the masses of gas on the two sides are adjusted as nearly as possible to equality, in order that any changes of temperature in the two sets of connecting tubes may compensate each other. This is effected with all the bulbs in melting ice, by adjusting the quantities of mercury in the bulbs M and S and equalizing the pressures. The bulb T is then heated in steam to determine the fundamental interval. A weight w_1 of mercury is removed from the overflow bulb M in order to equalize the pressures again. If W is the weight of the mercury at 0° C. which would be required to fill the bulb T at 0° C., and if $W + dW_1$ is the weight of mercury at 0° which would be required to fill a volume equal to that of the bulb in steam at t_1, we have the following equation for determining the coefficient of expansion a, or the fundamental zero T_0,

$$at_1 = t_1/T_0 = (w_1 + dW_1)/(W - w_1), \quad . \quad . \quad (13)$$

Similarly if w is the overflow when the bulb is at any other temperature t, and the expansion of the bulb is dW, we have a precisely similar equation for determining t in terms of T_0, but with t and w and dW substituted for t_1 and w_1 and dW_1. In practice, if the pressures are not adjusted to exact equality, or if the volumes of the connecting tubes do not exactly compensate, it is only necessary to include in w a small correction dw, equivalent to the observed difference, which need never exceed one part in ten thousand.

It is possible to employ the same apparatus at constant volume as well as at constant pressure, but the manipulation is not quite so simple, in consequence of the change of pressure. Instead of removing mercury from the overflow bulb M in connexion with the thermometric bulb, mercury is introduced from a higher level into the standard bulb S so as to raise its pressure to equality with that of T at constant volume. The equations of this method are precisely the same as those already given, except that w now signifies the "inflow" weight introduced into the bulb S, instead of the overflow weight from M. It is necessary, however, to take account of the pressure-coefficient of the bulb T, and it is much more important to have the masses of gas on the two sides of the apparatus equal than in the other case. The thermometric scale obtained in this method differs slightly from the scale of the manometric method, on account of the deviation of the gas compressed at 0° C. from Boyle's law, but it is easy to take account of this with certainty.

Another use to which the same apparatus may be put is the accurate comparison of the scales of two different gases at constant volume by a differential method. It is usual to effect this comparison indirectly, by comparing the gas thermometers separately with a mercury thermometer, or other secondary standard. But by using a pair of bulbs like M and S simultaneously in the same bath, and measuring the small difference of pressure with an oil-gauge, a higher order of accuracy may be attained in the measurement of the small differences than by the method of indirect comparison. For instance, in the curves representing the difference between the nitrogen and hydrogen scales (Fig. 1), as found by Chappuis by comparison of the nitrogen and hydrogen thermometers with the mercury thermometer, it is probable that the contrary flexure of the curve between 70° and 100° C. is due to a minute error of observation, which is quite as likely to be caused by the increasing aberrations of the mercury thermometer at these temperatures as by the difficulties of the manometric method. It may be taken as an axiom in all such cases that it is better to measure the small difference itself directly than to deduce it from the much more laborious observations of the separate magnitudes concerned.

§ 17. *Expansion Correction.*—In the use of the mercury thermometer we are content to overlook the modification of the scale due to the expansion of the envelope, which is known as Poggendorf's correction, or rather to include it in the scale correction. In the case of the gas thermometer it is necessary to determine the expansion correction separately, as our object is to arrive at the closest approximation possible to the absolute scale. It is a common mistake to imagine that if the rate of expansion of the bulb were uniform, the scale of the apparent expansion of the gas would be the same as the scale of the real expansion—in other words, that the correction for the expansion of the bulb would affect the value of the coefficient of expansion $1/T_0$ only, and would be without effect on the value of the temperature t deduced. A result of this kind would be produced by a constant error in the initial pressure on the manometric method, or by a constant error in the initial volume on the volumetric method, or by a constant error in the fundamental interval on any method, but *not* by a constant error in the coefficient of expansion of the bulb, which would produce a modification of the scale exactly analogous to Poggendorf's correction. The correction to be applied to the value of t in any case to allow for any systematic error or variation in the data is easily found by differentiating the formula for t with respect to the variable considered. Another method, which is in some respects more instructive, is the following:—

Let T be the function of the temperature which is taken as the basis of the scale considered, then we have the value of t given by the general formula (1), already quoted in § 3. Let dT be the correction to be added to the observed value of T to allow for any systematic change or error in the measurement of any of the data on which the value of T depends, and let dt be the corresponding correction produced in the value of t, then substituting in formula (1) we have,

$$t+dt=100(T-T_0+dT-dT_0)/(T_1-T_0+dT_1-dT_0),$$

from which, provided that the variations considered are small, we obtain the following general expression for the correction to t,

$$dt=(dT-dT_0)-(dT_1-dT_0)t/100 \quad . \quad . \quad (14)$$

It is frequently simpler to estimate the correction in this manner, rather than by differentiating the general formula.

In the special case of the gas thermometer the value of T is given by the formula

$$T=pV/RM=pV/R(M_0-M_2), \quad . \quad . \quad (15)$$

where p is the observed pressure at any temperature t, V the volume of the thermometric bulb, and M the mass of gas remaining in the bulb. The quantity M cannot be directly observed, but is deduced by subtracting from the whole mass of gas M_0 contained in the apparatus the mass M_2 which is contained in the dead space and overflow bulb. In applying these formulæ to deduce the effect of the expansion of the bulb, we observe that if dV is the expansion from 0° C., and V_0 the volume at 0° C., we may write

$$V=V_0+dV. \quad T=p(V_0+dV)/RM=(pV_0/RM)(1+dV/V_0),$$

whence we obtain approximately

$$dT=TdV/V_0 \quad . \quad . \quad . \quad . \quad (16)$$

If the coefficient of expansion of the bulb is constant and equal to the fundamental coefficient f (the mean coefficient between 0° and 100° C.), we have simply $dV/V_0=ft$; and if we substitute this value in the general expression (14) for it, we obtain

$$dt=(T-T_1)ft=ft(t-100) \quad . \quad . \quad (17)$$

Provided that the correction can be expressed as a rational integral function of t, it is evident that it must contain the factors t and $(t-100)$, since by hypothesis the scale must be correct at the fixed points 0° and 100° C., and the correction must vanish at these points. It is clear from the above that the scale of the gas thermometer is not independent of the expansion of the bulb even in the simple case where the coefficient is constant. The correction is by no means unimportant. In the case of an average glass or platinum reservoir, for which f may be taken as 0·000025 nearly, the correction amounts to −0·0625° at 50° C., to 3·83° at 445° C., and to 22·5° at 1000° C.

The value of the fundamental coefficient f can be determined with much greater accuracy than the coefficient over any other range of temperature. The most satisfactory method is to use the bulb itself as a mercury weight thermometer, and deduce the cubical expansion of the glass from the absolute expansion of mercury as determined by Regnault. Unfortunately the reductions of Regnault's observations by different calculators differ considerably even for the fundamental interval. The values of the fundamental coefficient range from ·00018153 Regnault, and ·00018210 Broch, to ·00018253 Wüllner. The extreme difference represents an uncertainty of about 4 per cent. (1 in 25) in the expansion of the glass. This uncertainty is about 100 times as great as the probable error of the weight thermometer observations. But the expansion is even less certain beyond the limits of the fundamental interval. Another method of determining the expansion of the bulb is to observe the linear expansion of a tube or rod of the same material, and deduce the cubical expansion on the assumption that the expansion is isotropic. It is probable that the uncertainty involved in this assumption is at least of the same order as the other in the case of glass or porcelain bulbs, on account of the difficulty of perfect annealing. In the case of metallic bulbs it is probable that this assumption is more nearly correct, provided that they have been perfectly annealed.

Except for small ranges of temperature, the assumption of a constant coefficient of expansion is not sufficiently exact. It is therefore usual to assume that the coefficient is a linear function of the temperature, so that the whole expansion from 0° C. may be expressed in the form $dV=t(a+bt)V_0$, in which case the fundamental coefficient $f=a+100b$. Making this substitution in the formula already given, we obtain the whole correction

$$dt=(f+bT)\,t\,(t-100) \quad . \quad . \quad . \quad (18)$$

It will be observed that the term involving b becomes of considerable importance at high temperatures. Unfortunately, it cannot be determined with the same accuracy as f, because the conditions of observation at the fixed points are much more perfect than at other temperatures. Provided that the range of the observations for the determination of the expansion is coextensive with the range of the temperature measurements for which the correction is required, the uncertainty of the correction will not greatly exceed that of the expansion observed at any point of the range. It is

not unusual, however, to deduce the values of b and f from observations confined to the range 0° to 100° C., in which case an error of 1 per cent., in the observed expansion at 50° C., would mean an error of 60 per cent. at 445°, or of 360 per cent. at 1000° C. Moreover, it by no means follows that the average value of b between 0° and 100° C. should be the same as at higher or lower temperatures. The method of extrapolation would therefore probably lead to erroneous results in many cases, even if the value could be determined with absolute precision over the fundamental interval. It is probable that this expansion correction, which cannot be reduced or eliminated like many of the other corrections which have been mentioned, is the chief source of uncertainty in the realization of the absolute scale of temperature at the present time. The uncertainty is of the order of one part in five or ten thousand on the fundamental interval, but may reach 0·5° at 500° C., and 2° or 3° at 1000° C.

§ 18. *Thermodynamical Correction.*—Of greater theoretical interest, but of less practical importance on account of its smallness, is the reduction of the scale of the gas thermometer to the thermodynamical scale. The theory of the reduction was first given by Thomson, and the requisite experimental data for air, hydrogen, and carbonic acid were subsequently obtained by Joule and Thomson in their celebrated series of experiments on the "Thermal Effects of Fluids in Motion" (*Phil. Trans.*, 1854, 1862). These experiments have been discussed by Thomson (*Ency. Brit.*, vol. xi. p. 554), and more recently by a number of other writers, but little has been done in the direction of the practical application of the results to the construction of a table of corrections for the reduction of the scales of different gas thermometers. This is the more to be regretted as the original table of corrections for the air thermometer given by Joule and Thomson in their first paper (1854) was calculated from imperfect data and formulæ. Unfortunately, this table has been very widely quoted, even by later authors (cf. Guillaume, *Thermometry*, 1889), and has given rise to the impression that the corrections calculated by the method of Thomson and Joule are of no value as compared with those obtained by direct comparison of the scales of different gases. It may therefore be of interest to give a more complete table of corrections calculated from their later experiments, and to explain the method of calculation and discuss its limitations.

Lord Kelvin (*Ency. Brit.*, vol. xi. p. 554), assuming that the cooling effect in adiathermal expansion through a porous plug varies inversely as the square of the absolute temperature, and taking Regnault's values for the coefficients of expansion at constant pressure, finds the following results for the absolute zero :—

TABLE II.—*Absolute Zero from Regnault's Expansion-Coefficients.*

Gas employed . . .	Air.	Hydrogen.	Carbonic Acid.
Coefficient of expansion . α	·0036706	·0036613	·0037100
Fundamental zero of gas . T_0	272·44	273·13	269·50
Correction to abs. zero $\theta_0 - T_0$	+0·70	−0·13	+4·4
Absolute zero deduced . θ_0	273·14	273·00	273·90

He concludes that the absolute zero is probably within one-tenth of a degree of 273·0, at which point it may be taken (as a round number) until more accurate experiments are forthcoming. He does not consider the case of the pressure-coefficient at constant volume. The objection has been raised to his formula, that the simple inverse square law does not represent the observed increase in the heating effect with rise of temperature in the case of hydrogen, and that it does not satisfy the observations on carbonic acid very accurately. It appears that more consistent results might be obtained by taking account of the "covolume" b, which affords an explanation of the heating effect for hydrogen, and by employing the more general equation (see THERMODYNAMICS, equation (17), § 11),

$$v - b = R\theta/p - c, \quad . \quad . \quad . \quad . \quad (19)$$

in which b is a constant depending on the volume of the molecules themselves, and c is a term depending on the molecular co-aggregation, which may be assumed to vary inversely as the nth power of the absolute temperature. The index n is equal to 2 in the Joule-Thomson equation, but is probably different for different gases.

Calculation of Correction.—In order to calculate the value of the correction by this equation, it is preferable to write it in the form $\theta = pv/R + q$, where q is a small quantity of the same dimensions as a temperature. Comparing this with equation (19), we have generally

$$q = (c - b)p/R \quad . \quad . \quad . \quad . \quad (20)$$

In using a gas thermometer we assume an equation of the form $T = pv/R_1$, in which T is the temperature on the scale of the gas thermometer, and R_1 is a constant, differing slightly from R, and depending on the method of thermometry employed. The value of R_1 has to be determined by observations at the fixed points 0° and 100° C., which gives the relations

$$R_1 = (p_1v_1 - p_0v_0)/100, \quad R = R_1(1 + (q_1 - q_0)/100), \quad . \quad (21)$$

where p_0, v_0, q_0 are the values of p, v, q, at 0° C., and p_1, v_1, q_1 are the values at 100° C. Similarly for the value of the freezing-point of water on the absolute thermodynamical scale, we have

$$\theta_0 = p_0v_0/R + q_0 = T_0 + q_0 - (q_1 - q_0)\theta_0/100\,; \quad . \quad . \quad (22)$$

and for the correction dt to be added to the temperature Centigrade on the scale of the gas thermometer to reduce to temperature Centigrade on the thermodynamical scale, we have by formula (14),

$$dt = (q - q_0) - (q_1 - q_0)\, t\,/100 \quad . \quad . \quad . \quad (23)$$

The values of c and b for the gas may be deduced from the observations on the cooling effect Q for a difference of pressure P in terms of the specific heat S at constant pressure, as explained in the article THERMODYNAMICS, § 10, by means of the relation

$$SQ/P = (n+1)c - b \quad . \quad . \quad . \quad . \quad (24)$$

If, for instance, we take from the observations of Joule and Thomson on the cooling effect in the case of carbonic acid for a change of pressure $P = 100$ inches of mercury, the values $Q = 4·64°$ C. at 0° C., and 2·15° at 95·6°, assuming the index $n = 2$, we should find $c_0 = 4·62$ c.c. at 0° C., and $b = 2·18$ c.c. The specific heat S is taken as 0·85 joule, but this is a little uncertain. The value of q is easily found in terms of c and b by equation (20), but as it depends on p as well as θ, its value is different for different methods of thermometry. In the case of the constant-pressure thermometer we have $p = p_0$, the initial pressure, but for the constant-volume thermometer $p = p_0\theta/\theta_0$. Thus if $n = 2$, substituting in (22) and (23) we have the following very simple expressions for the correction for the constant-volume thermometer :—

$$\left.\begin{array}{l} \text{Zero correction (const. vol.), } \theta_0 - T_0 = 646\,C \\ \text{Scale correction } \quad ,, \quad ,, \quad dt = Ct(t - 100)/\theta \end{array}\right\} \quad . \quad (25)$$

where C is used as an abbreviation for the constant factor $c_0p_0/373R$, which has the following values if $n = 2$, $p_0 = 760$ mm. : air, C = ·00085 ; hydrogen, C = ·000132 ; carbonic acid, C = ·00650.

For the constant-pressure thermometer, the constant C has the values already given for each gas, and the corrections are as follows :—

$$\left.\begin{array}{l} \text{Zero correction, } \theta_0 - T_0 = 846\,C - bp_0/R \\ \text{Scale correction, } dt = Ct(t - 100)(1·732 + 273/\theta)/\theta \end{array}\right\} \quad . \quad (26)$$

The covolume b occurs only in the zero-correction of the constant-pressure thermometer. All the corrections vary in direct proportion to the initial pressure p_0 at 0° C. By assuming a standard value such as 273·0 for the absolute zero θ_0, the formulæ for the zero-correction will give the value of T_0, the reciprocal of the fundamental expansion- or pressure-coefficient for any initial pressure p_0.

The values of the corrections given in Table IV. have been calculated by the above formulæ, assuming $n = 2$. If the corrections between 0° and 100° for the constant-volume thermometer are increased in the proportion of 4/3, to correspond with an initial pressure of 100 cms., they are found to agree very fairly in general character and also in magnitude with those found experimentally by Chappuis, and illustrated in Fig. 1. The theory may also be verified by comparison with the observed values of the pressure-coefficients.

TABLE III.—*Absolute Zero from Pressure-Coefficients.*

Observer . . .	Regnault, $p=76$ cms.			Chappuis, $p=100$ cms.		
Gas employed . .	Air.	H_2.	CO_2.	N_2.	H_2.	CO_2.
Coef. $\times 10^7$ . .	36650	36678	36880	36748	36625	37250
Fund. zero T° . .	272·85	272·64	271·2	272·11	273 03	268·5
$\theta_0 - T_0$, $n=2$ . .	+0·56	+0·09	+4·2	+0·86	+0·11	+5·5
Abs. zero θ_0 . .	273 41	272 73	275·4	272·97	273·14	274·0
$\theta_0 - T_0$, $n=1$ . .	+0 83	+0 13	+6·4	+1·30	+0·17	+8 4
Abs. zero θ_0 . .	273·68	272·77	277·6	273·41	273 20	276·9

It is at once evident from this table that Regnault's values for the pressure-coefficients, which have been so long accepted, disagree among themselves, and cannot be reconciled with those of Chappuis. His values for the expansion-coefficients, on the contrary, are fairly concordant, and have been confirmed by subsequent work. This would indicate that, contrary to his own belief, the constant-pressure thermometer was more accurate in his hands than the constant-volume thermometer. Assuming that the Joule-Thomson effect for air may be applied to nitrogen, the values of θ_0 deduced from the observations of Chappuis on the pressure-coefficients of nitrogen and hydrogen at 100 cms. agree very fairly with those deduced by Lord Kelvin from the expansion-coefficients. For the sake of comparison, the values of the corrections have also been calculated on the assumption $n=1$, which corresponds to the formula of van der Waals. It will be seen that this introduces discrepancies so large as to be practically inadmissible. It would also make the scale correction for the constant-volume thermometer vanish, which cannot be reconciled with Chappuis's results (Fig. 1). So far as these particular observations alone are concerned, it would be possible to obtain better agreement empirically by the choice of some other values for the index n, but the real difficulty lies in reconciling the results by the Joule-Thomson method with the direct observations of specific volume by Amagat and others at higher temperatures. According to Amagat, CO_2 is still a notably imperfect gas (c greater than b) at 260° C. But according to the values of c and b calculated from the Joule-Thomson effect, it should become "pluperfect" (c less than b) at 125° C. On account of the difficulty of making experiments on the cooling effect at different temperatures, the work of Joule and Thomson has not yet been repeated, except in the case of steam, which offers special facilities. It is evident that further experiments are desirable, but in the meantime it appears preferable to retain the value $n=2$ for the index, as it simplifies the formulæ, and satisfies the observations within the probable limits of experimental error, over the range of the experiments 0° – 100° C.

TABLE IV.—*Thermodynamical Correction of Gas Thermometers.*

t Cent.	At Constant Volume, Initial Pressure 760 mm.			At Constant Pressure, $p_0=$ 760 mm.

§ 19. *Limitations.*—In the application of the gas thermometer to the measurement of high temperatures certain difficulties are encountered which materially limit the range of measurement and the degree of accuracy attainable. These may be roughly classified under the heads—(1) changes in the volume of the bulb; (2) leakage, occlusion, and porosity; (3) chemical change and dissociation. The difficulties arise partly from defects in the materials available for the bulb, and partly from the small mass of gas enclosed. The troubles due to irregular changes of volume of glass bulbs, which affect the mercury thermometer at ordinary temperatures, become so exaggerated at higher points of the scale as to be a serious source of trouble in gas thermometry in spite of the twentyfold larger expansion. For instance, the volume of a glass bulb will be diminished by from one-quarter to one-half of 1 per cent. the first time it is heated to the temperature of boiling sulphur (445° C.). This would not matter so much if the volume then remained constant. Unfortunately, the volume continues to change, especially in the case of hard glass, each time it is heated, by amounts which cannot be predicted, and which are too large to neglect. The most accurate method of taking account of these variations in a series of observations, without recalibrating and refilling and cleaning the bulb, is to assume the known constant value of the coefficient of expansion of the gas, and to calculate the volume of the bulb at any time by taking observations in ice and steam (*Phil. Trans.*, A. 1891, vol. 182, p. 124). Similar changes take place with porcelain at higher temperatures. Metallic bulbs are far more perfect than glass bulbs in this respect. It is probable that silica bulbs would be the most perfect. The writer suggested the use of this material (in the *Journal of the Iron and Steel Institute* for 1892), but failed to construct bulbs of sufficient size. Mr Shenstone, however, has recently succeeded, and there seems to be a good prospect that this difficulty will soon be minimized. The difficulties of leakage and porosity occur chiefly with porcelain bulbs, especially if they are not perfectly glazed inside. A similar difficulty occurs with metallic bulbs of platinum or platinum-iridium, in the case of hydrogen, which passes freely through the metal by occlusion at high temperatures. The difficulty can be avoided by substituting either nitrogen or preferably argon or helium as the thermometric material at high temperatures. With many kinds of glass and porcelain the chemical action of hydrogen begins to be appreciable at temperatures as low as 200° or 300° C. In any case, if metallic bulbs are used, it is absolutely necessary to protect them from furnace gases which may contain hydrogen. This can be effected either by enclosing the bulb in a tube of porcelain, or by using some method of electric heating which cannot give rise to the presence of hydrogen. At very high temperatures it is probable that the dissociation of diatomic gases like nitrogen might begin to be appreciable before the limit of resistance of the bulb itself was reached. It would probably be better, for this reason, to use the monatomic and extremely inert gases argon or helium.

§ 20. *Other Methods.*—Many attempts have been made to overcome the difficulties of gas pyrometry by adopting other methods of measurement. Among the most interesting may be mentioned—(i.) The variation in the wave-length of sound. The objection to this method is the difficulty of accurately observing the wave-length, and of correcting for the expansion of the material of the tubes in which it is measured. There is the further objection that the velocity varies as the square root of the absolute temperature. (ii.) A similar method, but more promising, is the variation of the refractivity of a gas, which can be measured with great accuracy by an interference method. Here again there is difficulty in determining the exact length of the heated column of gas, and in maintaining the temperature uniform throughout a long column at high temperatures. These difficulties have been

ingeniously met by D. Berthelot (*Comptes Rendus*, 120, p. 831). But the method is not easy to apply, and the degree of accuracy attainable is probably inferior to the bulb methods. (iii.) Methods depending on the effusion and transpiration of gases through fine orifices and tubes have been put in practice by Barus and by the writer. The method of transpiration, when the resistance of the tube through which the current of gas is passed is measured on the Wheatstone bridge principle (*Nature*, 23rd March 1899), is extremely delicate, and the apparatus may be made very small and sensitive, but the method cannot be used for extrapolation at high temperatures until the law of increase of resistance has been determined with certainty. This may be successfully accomplished in the near future, but the law is apparently not so simple as is usually supposed.

On account of these and similar difficulties, the limit of gas thermometry at the present time must be placed at 1200° C., or even lower, and the accuracy with which temperatures near 1000° C. are known does not probably exceed 5° C. Although measurements can be effected with much greater consistency than this by means of electrical pyrometers, the absolute values corresponding to those temperatures must remain uncertain to this extent, inasmuch as they depend on observations made with the gas thermometer. Temperatures as high as 2000° C. have been determined, but only by extrapolation of empirical formulæ or other methods of estimation.

Electrical Thermometry.

§ 21. The convenience of the mercurial thermometer lies in the fact that it is complete in itself, and can be read without subsidiary appliances beyond a magnifying glass. Its weakness lies in the very limited range of each single instrument, and in the troublesome and often uncertain corrections which must be applied to its readings in all work of precision. Electrical thermometers have the disadvantage of requiring auxiliary apparatus, such as galvanometers and resistances, the use of which involves some electrical training. But they far surpass the mercurial thermometer in point of range, delicacy, and adaptability, and can be applied to many investigations in which ordinary thermometers are quite useless.

There are two kinds of electrical thermometers, which depend on different effects of heat on the electrical properties of metals: (1) The *Thermocouple*, or *Thermopile*, which depends on the production of a thermoelectric force when the junctions of different metals in an electric circuit are at different temperatures; and (2) the *Electrical Resistance Thermometer*, the action of which depends on the fact that the resistance of a pure metal to the passage of an electric current increases very considerably when the temperature is raised. The theory of the thermocouple is discussed at some length in the article Thermoelectricity, as it possesses many points of interest, and has been studied by many skilful experimentalists. The electrical resistance thermometer is of more recent origin; but although the theory has been less fully developed, the practice of the method bids fair to surpass all others in the variety and accuracy of its applications. In order to secure the widest possible range and the greatest constancy, in either variety of electrical thermometer, advantage is taken of the great stability and infusibility characteristic of the metals of the platinum group. Other metals are occasionally used in work at low temperatures with thermocouples for the sake of obtaining a larger electromotive force, but the substitution is attended with loss of constancy and uncertainty of reduction, unless the range is greatly restricted.

§ 22. *Applications of the Thermocouple.*—The principal uses of the thermocouple in thermometry are for measuring high temperatures, and for measuring small differences of temperature, more particularly when the temperature is required to be measured *at a point*, or in a very small space. The electromotive force of the couple depends only on the temperature at the plane of junction of the two metals, which can be very exactly located. A typical instance of a measurement to which the thermocouple is peculiarly suited, is the determination of the cyclical variations of temperature at accurately measured depths from one-tenth to one-hundredth of an inch in the metal of the cylinder of a heat engine, the interior surface of which is exposed to cyclical variations of temperature in the working of the engine.[1] The exact depth of the plane of junction can be measured without difficulty to the thousandth of an inch. The insertion of the wire makes the least possible disturbance of the continuity of the metal. There is no lag, as the thermometer itself is part of the metal. The instantaneous value of the temperature at any particular point of the stroke can be measured separately by setting a periodic contact to close the circuit of the galvanometer at the desired point. A further advantage is gained by measuring only the difference of temperature between two junctions of a thermocouple at different depths, instead of the whole interval from some fixed point. None of these advantages could be secured by the use of any ordinary thermometer; some depend on the fact that the method is electrical, but some are peculiar to the thermocouple, and could not be otherwise attained.

On the other hand, the thermocouple is not well suited for thermometry of precision, on account of the smallness of the electromotive force, which is of the order of ten microvolts only per degree for the most constant couples. By the use of very delicate galvanometers it is possible to read to the hundredth or even in special cases to the thousandth of a degree on this small difference, but unfortunately it is not possible to eliminate accidental thermal effects in other parts of the circuit due to small differences of temperature and material. These accidental effects seldom amount to less than one or two microvolts even in the best work, and limit the accuracy attainable in temperature measurement to about the tenth of a degree with a single platinum thermocouple. This limit can be surpassed by using couples of greater thermoelectric power and less permanence, or by using a pile or series of couples, but in either case it is doubtful whether the advantage gained in power is not balanced by loss of simplicity and constancy. A method of avoiding these effects, which the writer has found to be of great use in delicate thermoelectric researches, is to make the whole circuit, including all the terminals and even the slide-wire itself, of pure copper. Platinoid, german silver, constantan, and other alloys most commonly used for resistances and slide-wires, are particularly to be avoided, on account of their great thermoelectric power when connected to copper. Manganin and platinum-silver are the least objectionable, but the improvement effected by substituting copper is very marked. It is clear that this objection to the use of the couple does not apply with the same force to high temperatures, because the electromotive force of the couple itself is greater, and the accuracy attainable is limited by other considerations.

§ 23. *The Resistance Thermometer.*—In practice the resistance thermometer is almost invariably made of platinum, since there is very seldom any advantage to be gained by the substitution of baser metals. The instrument

[1] Hall, *Trans. Amer. Inst. Elect. Eng.*, 1891, vol. viii. p. 226; Callendar and Nicolson, *Proc. Inst. C. E.*, vol. cxxxi. p. 1.

is for this reason often referred to simply as the "platinum thermometer." It is important that the platinum should be pure, both for the sake of uniformity and also because the change of electrical resistance with temperature is greater the purer the metal. The observation of the fundamental coefficient, which is ·00390 (or rather larger than the coefficient of expansion of a gas) for the purest metal hitherto obtained, is one of the most delicate tests of the purity of the metal. In addition to the constancy and infusibility of the metal, a special advantage which is secured by the use of platinum is the close agreement of the thermodynamical scale with the platinum scale of temperature, as defined by the formula

$$pt = 100(R - R_0)/(R_1 - R_0), \quad . \quad . \quad . \quad (27)$$

in which the symbol pt stands for the temperature on the platinum scale Centigrade, and R, R_1, and R_0 are the observed resistances of the thermometer at the temperatures pt, 100°, and 0° C. respectively. A platinum thermometer is generally arranged to read directly in degrees of temperature on the platinum scale, just as a mercury thermometer is graduated in degrees of the mercury scale. The reduction to the scale of the gas thermometer is most conveniently effected by the difference formula

$$t - pt = dt(t - 100)/10{,}000, \quad . \quad . \quad (28)$$

in which d is a constant, called the difference-coefficient, the value of which for pure platinum is about 1·50, but varies slightly for different specimens. This formula was first given by the writer as the result of a series of comparisons of different platinum wires with each other and with other metals, and also with an air thermometer over the range 0° to 625° C. The platinum wire in these comparisons was enclosed inside the bulb of the air thermometer itself, and disposed in such a manner as to be at the mean temperature of the bulb in case the temperature were not quite uniform throughout (*Phil. Trans.*, A. 1887, p. 161). The formula was subsequently verified by Griffiths (*Phil. Trans.*, A. 1891), by the comparison of platinum thermometers of different construction at temperatures up to the boiling-point of sulphur, 445° C., and by Heycock and Neville (*Jour. Chem. Soc.*, February, 1895), by the observation of a number of higher points up to the freezing-point of copper at 1082° C., which they showed to agree with the most probable mean of all the best determinations by various methods of gas thermometry. At still higher temperatures, beyond the present range of the gas thermometer, the writer has succeeded in obtaining presumptive evidence of the validity of the same formula by comparison with the scales of the expansion and the specific heat of platinum, which appear to follow similar laws (*Phil. Mag.*, December 1899). If we assume that the coefficient of expansion of platinum, the coefficient of increase of resistance, and the specific heat are all three linear functions of the temperature, we obtain results which are in agreement within the limits of error of observation up to the fusing point of platinum itself. Quite recently the same formula has been independently verified by the comparison of platinum thermometers with the constant-volume nitrogen thermometer by Harker and Chappuis (*Phil. Trans.*, A. 1900), working at the International Bureau at Sèvres, over the range 0° to 650° C. It has also been shown by the experiments of Fleming and others that the same formula satisfies very closely the observations on the variation of electrical resistance of other metals over wide ranges of temperature. Although the theoretical explanation of the formula has not yet been given, owing to our ignorance of the true nature of electrical conduction and of the molecular constitution of metals, it may be regarded from an empirical point of view as being one of the most accurately established of all thermometric formulæ. It will be observed that it also represents the simplest possible type of divergence from the thermodynamical scale. It has for this reason been proposed to adopt a scale of temperature based on this formula as a practical standard of reference pending more accurate determinations of the thermodynamical scale at high temperatures. The advantage of this practical standard would be that all measurements made at the present time could be referred to it directly with much greater accuracy than they can be referred to the gas thermometer. The latter instrument is extremely difficult to use, especially at high temperatures, and cannot be directly applied to the majority of investigations. The order of accuracy attainable with a platinum thermometer is at least ten times greater than with the gas thermometer, on account of the uncertainty of the expansion of the envelope, a source of error from which the platinum thermometer is free. By adopting the platinum thermometer as a practical standard of reference, a higher order of accuracy of comparison is attainable, in addition to much greater ease and convenience of manipulation.

§ 24. *Methods and Apparatus.*—The methods of electrical thermometry may be roughly classified under two heads as (1) deflection methods, in which the temperature is deduced from the observed deflection of a galvanometer; and (2) balance methods, in which the resistance or the electromotive force is balanced against a known adjustable resistance or potential difference. The former methods are most suitable for rough work and rapid reading, the latter for the accurate measurements. In the practice of the deflection method it is customary to use a movable-coil galvanometer, the sensitiveness of which can be varied by varying the resistance in circuit, or by varying the stiffness of the suspension. The accuracy attainable is of the order of one-half of 1 per cent. on the deflection, and is limited by variations of resistance of the galvanometer, and by the imperfect elasticity of the suspension. In any case the scale of the galvanometer should be "calibrated" or tested for uniformity. In this kind of work the thermocouple has the advantage over the resistance thermometer in that the latter requires an auxiliary battery to supply the current; but in many cases this is no disadvantage, because it permits a greater latitude of adjustment, and makes it possible to obtain greater power than with the thermocouple. For example, the electromotive force of a 10 per cent. Rh. Pt. – Pt. couple at 500° C. is only about 4 millivolts (·004 volt). To read so small a potential difference with any accuracy requires a suspended coil galvanometer with a mirror and scale. Even with the smallest resistance thermometer, with a coil containing only two inches of fine wire, it is easy to have a difference of potential of 40 or 50 millivolts at 500° C., which is well within the range of an ordinary portable pivoted millivoltmeter, such as is commonly used in every power station for measuring electric currents by the fall of potential method. With larger thermometers the power available would be much greater. This is most advantageous, not only for accurate work, but also for practical applications, in which automatic records are often a great convenience. With a resistance thermometer it is easy to obtain records in pen and ink on a scale of an inch to the degree by a balance method. With a thermocouple it is necessary to employ photography and very delicate apparatus to secure a similar scale.

In cases where it is desired to obtain greater accuracy without abandoning the quickness of reading which is the principal advantage of the deflection method, it is possible to combine the two methods by balancing part of the

potential difference by means of a potentiometer (see ELECTRICITY: *Electric Current*) and using the galvanometer for the small changes only. In cases where the greatest accuracy is required, a very sensitive galvanometer should be used, and the whole of the potential difference should be balanced as nearly as possible, leaving very little to depend on the deflection of the galvanometer. The degree of sensitiveness and accuracy obtainable depends primarily on the delicacy of the galvanometer, on the power available, and on the steadiness of the conditions of experiment. For thermometry of precision the resistance thermometer possesses three very great advantages over the thermocouple: (1) The power available, owing to the use of a battery, is enormously greater; (2) it is possible completely to eliminate the errors due to accidental thermal effects by reversing the battery; (3) the Wheatstone bridge method can be employed in place of the potentiometer, so that the constancy of the battery is immaterial, and it is not necessary to use a standard cell. The conditions to be satisfied in the attainment of the greatest possible accuracy in the measurement of temperature by this method differ somewhat from those which obtain in ordinary measurements of resistance, so that a special type of apparatus has been evolved for the purpose, a brief description of which will be given.

§ 25. *Compensated Bridge Apparatus.*—It is necessary that the thermometer should be connected to the measuring apparatus by wires or "leads" of considerable length, generally at least two or three metres, in order to avoid exposing the galvanometer and resistance box, or other delicate parts of the apparatus, to changes of temperature. It is also essential that the leads should not be too thick or heavy, for convenience in handling, and to prevent conduction of heat along the stem of the thermometer. The resistance of that part of the leads which is exposed to variations of temperature necessarily changes, and would give rise to serious

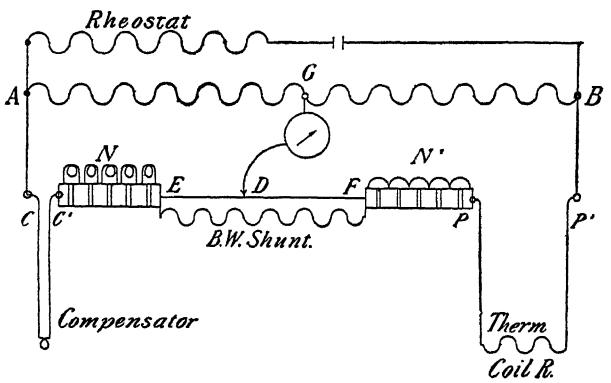

FIG. 5.—Diagram of Compensated Bridge Method.

errors if it were not determined or compensated. The method now generally adopted in accurate work is to compensate the variations of resistance of the leads by an exactly similar pair of dummy leads called the "compensator" and connected as shown diagrammatically in Fig. 5. The battery, consisting of a single cell, with a rheostat and reversing key in circuit, is connected to the terminals AB of the two equal resistance coils AG, GB, which form the ratio arms of the balance. These coils must be carefully tested for equality of temperature-coefficient, and placed in close proximity to each other so as to be always at the same temperature. If they are interwound on the same reel, they must be most carefully insulated from each other. In parallel circuit with the ratio coils are connected the compensator CC′ and the balancing resistances C′E, on one side of the bridge-wire EF, and the compensating resistances FP and the pyrometer and leads PRP′ on the other side. The galvanometer is connected to the point G between the ratio coils, and to the sliding contact D on the bridge-wire. Since the ratio coils are always equal, equal changes of resistance on either side of D are eliminated, and do not affect the balance. Thus the changes of the pyrometer leads PP′ are balanced by the equal changes of the compensator leads CC′ on the other side. As a further refinement, which is of some importance in delicate work, the ends of the compensator leads are connected by a short piece of the same wire as the pyrometer coil. For instance, in observing the variations of temperature of the steam in the cylinder of a steam engine at different points of the stroke with a very delicate thermometer made of wire one-thousandth of an inch in diameter (*Proc. Inst. C. E.*, vol. cxxxi. Fig. 16, p. 23), the ends of the fine wire attached to the thick leads could not follow the rapid variations of temperature, and it was found necessary to adopt this device to eliminate the end-effect. It is also useful in other cases to eliminate the effect of conduction along the leads in cooling the ends of the fine wire coil. The balancing resistances C′E are made of some alloy such as manganin or platinum-silver, the resistance of which varies very little with change of temperature. Platinum-silver is probably the best material, as it can be perfectly annealed at a red heat without risk of burning, and is then extremely constant, whereas manganin resistances are liable to change, and require frequent recalibration. Unless the box can be kept at an absolutely constant and uniform temperature, which is not impossible but often inconvenient, it is necessary to allow for the change of resistance of the balancing coils C′E due to change in the temperature of the box. The temperature of the coils cannot be accurately determined with a mercury thermometer unless they are immersed in oil, but even in that case it is necessary to know the temperature coefficient of each individual coil. A more convenient and accurate method, which eliminates the correction automatically, is to compensate each individual coil of the balancing coils C′E by a corresponding compensating coil at FP on the other side of the bridge-wire. The compensating coils are made of platinum, also annealed at a red heat, and each is placed in the box in close proximity to the coil it is intended to compensate. Each balancing coil and its compensator are tested together at various temperatures between 10° and 30° C., and are adjusted until their difference remains constant for any small variation of temperature in the neighbourhood of 20° C. This method of compensation was applied by the writer in 1887, but has not been generally adopted on account of the labour involved in adjusting the coils. The absolute values of the resistances are immaterial, but it is necessary to know the relative values with the greatest possible accuracy. For this reason it is preferable to arrange the resistances in the binary scale, each resistance being equal to twice the next smaller resistance, or to the sum of all the smaller resistances, the two smallest resistances being made equal. This arrangement permits the greatest accuracy of comparison in the simplest manner with the fewest observations. The bridge-wire EF provides a continuous scale for reading small changes of resistance. Any change of resistance of the pyrometer coil necessitates the movement of the balance point D through an equivalent resistance along the bridge-wire. The equivalent resistance of the bridge-wire per unit length of the attached scale is preferably adjusted, by means of a shunt shown in parallel with it in Fig. 5, to be an exact submultiple of the smallest resistance coil. It is usual also to adjust the resistances of the thermometers so that their fundamental intervals are convenient multiples of this unit, generally either 100, 200, 500, or 1000, so that the bridge-wire may read directly in degrees of temperature on the platinum scale. It is easy to get a scale of 10 cms. or more to the degree, and it is not difficult with a suitable galvanometer to read to the ten-thousandth part of a degree. The length of the bridge-wire itself need not be more than 20 or 30 cms., as the balancing resistances enable the scale to be indefinitely extended. Thus the instrument possesses the great advantage over the mercury thermometer that the most open scale may be easily secured without unwieldy length, and without restricting the range of each thermometer.

§ 26. *Errors and Corrections.*—It is most instructive to consider the errors and corrections involved in platinum thermometry on the same lines as those on which the corresponding errors of the mercury thermometer have already been treated.

(I) The changes of zero of the mercury thermometer arise chiefly from the small expansibility of mercury combined with the imperfect elasticity of the containing tube. In platinum thermometry the containing tube has nothing to do with the reading, and the effect of any possible strain of the fine wire of the coil is minimized by its small dimensions and by the large temperature-coefficient of the increase of resistance, which is more than twenty times greater than the coefficient of apparent expansion of mercury in glass. It is not surprising, therefore, that the changes of zero of a platinum thermometer should be practically negligible, provided that the wire is not strained and contaminated with impurities. It is probable that with ordinary care the changes of zero due to exposure to any given limits of temperature are in all cases less than the limit of accuracy of observation, due to other causes at the extreme limit of the range considered.

(II) *The fundamental interval* of each thermometer must be determined as usual by observations in ice and steam, and a correction must be applied by the method already described in the case of the mercury thermometer. The difference of the temperature of

the steam from 100° C. should be determined on the platinum scale by the approximate formula

$$dpt_1 = \cdot 985 dt_1 = \cdot 0362(H-760) - \cdot 000020(H-760)^2 \quad . \quad (29)$$

(III) *Pressure Correction.*—The effect of change of pressure on a platinum thermometer of the ordinary tube form is of course nothing, as the wire itself is not exposed to the pressure. Even if the wire is naked and directly exposed to large changes of pressure, the change of reading is almost inappreciable. Similarly there is no source of error analogous to the effects of capillarity, which are so troublesome with delicate mercury thermometers.

(IV) *Stem Exposure.*—The reading of a platinum thermometer with compensated leads depends only on the temperature of the coil of wire forming the bulb, and not on the temperature of the stem, provided that the immersion is sufficient to avoid errors due to conduction or convection along the stem. It is desirable that the top of the bulb should be immersed to a depth equal to from three to five times the diameter of the tube, according to the size and the accuracy required.

(V) *Scale Correction.*—The reduction to the thermodynamical scale may be effected, within the limits of probable error of the most accurate measurements at present available, by the very simple difference formula (28) already given, over the whole range from −100° C. to +1100° C. This is in striking contrast with the mercury thermometer, which requires a cubic formula to cover the range 0° to 200° C. with equal accuracy. The value of the constant d in the formula varies but little, provided that the wire be fairly pure and the thermometers properly constructed. In order to determine its value in any special case, it is best to take an observation at the boiling-point of sulphur (S.B.P.) for temperatures above 0° C., or at that of oxygen for temperatures below 0° C. down to −200° C. It appears probable that there is a point of inflection in the curve of resistance-variation of platinum and some other metals in the neighbourhood of −200° C., and that the formula does not apply accurately below this point. It has been the custom for several years to assume the boiling-point of sulphur (S.B.P.) under normal pressure to be 444·53° C., as determined by Callendar and Griffiths, using a constant-pressure air thermometer, and to take the rate of change of temperature with pressure as ·082° per mm. from Regnault's observations. According to experiments made at Kew Observatory with platinum thermometers (Chree, *Proc. R. S.*, 1900), the rate of change is somewhat larger than that given by Regnault's formula, namely, about ·090° per mm., and it appears desirable to determine this constant with greater accuracy. The difference between the above formulæ reaches a tenth of a degree if the barometer differs by 12 mm. from 760 mm. The uncertainty in the absolute boiling-point of sulphur, however, is probably somewhat greater than one-tenth of a degree, on account of the uncertainty of the expansion correction of the gas thermometer (*Phil. Mag.*, December 1899). The thermodynamical correction of the gas thermometer, which amounts to half a degree, according to Table IV. above, is also to some extent uncertain, on account of the extrapolation. Provided, however, that some exact value of the S.B.P. is chosen for reference, for the reduction of observations with platinum thermometers, the results so reduced will be strictly comparable, and can be corrected at any subsequent time when the value of the S.B.P. is more accurately determined. The boiling-point of oxygen may be taken as −182·5° C. with sufficient approximation for a similar purpose.

(VI) *Calibration Correction.*—The calibration of the resistance box and the bridge-wire corresponds to the calibration of the stem of the mercury thermometer, but the process is much simpler for several reasons. It is more easy to obtain a uniform wire than a uniform tube. The scale of the wire is much more open, it corresponds to a very small part of the whole scale, and the process of calibration is easier. One box when calibrated will serve for any number of thermometers of different ranges and scales, and covers the whole range of temperature (see CALIBRATION, *Ency. Brit.*, vol. xxvi.).

§ 27. *Electrical Precautions.*—The platinum thermometer is so far superior to the mercury thermometer in all the points above enumerated that, if there were no other difficulties, no one would ever use a mercury thermometer for work of precision. In using a platinum thermometer, however, some electrical training is essential to obtain the best results. The manipulation and adjustment of a delicate galvanometer present formidable difficulties to the non-electrical observer. Bad contacts, faulty connexions, and defective insulation are not likely to trouble the practised electrician, but present endless possibilities of error to the tyro. A useful discussion of these and similar details is given in the paper by Chree already referred to. Bad insulation of the pyrometer and connexions can easily be detected, in the compensated instrument already described, by disconnecting one of the C leads from the battery and one of the P leads from the bridge-wire. Under these conditions the galvanometer should not deflect if the insulation is perfect. Defective insulation is most likely to be due to damp in the thermometer at low temperatures. This source of error is best removed by drying and hermetically sealing the thermometers. Trouble from bad contacts generally arises from the use of plugs for the resistance coils. If plugs are used, they must be specially designed so as not to disturb each other, and must be well fitted and kept very clean. Mercury cups with large copper terminals, well amalgamated, as used with standard resistance coils, are probably the simplest and most satisfactory method of changing connexions. Accidental thermoelectric effects in the circuit are a possible source of error, as with the thermocouple, but they are always very small if the thermometer is properly constructed, and are relatively unimportant owing to the large E.M.F. available. In any case they may be completely eliminated by reversing the battery. The heating effect of the current through the thermometer is often negligible, but should be measured and allowed for in accurate work. With a current of ·01 ampere the rise of temperature should not exceed $\frac{1}{100}$ or $\frac{2}{100}$ of a degree. With a delicate galvanometer it is possible to read to the ten-thousandth of a degree with a current of only ·002 ampere, in which case the heating effect is generally less than $\frac{1}{100}$ of a degree. It can be very easily measured in any case by changing from one cell to two, thus doubling the current in the thermometer, and quadrupling the heating effect. The correction is then applied by subtracting one-third of the difference between the readings with one and two cells from the reading with one cell. The correction is always very small, if a reasonably sensitive galvanometer is used, and is frequently negligible, especially in differential work, which is one of the most fruitful applications of the platinum thermometer.

§ 28. *Construction of Thermometers.*—One of the chief advantages of the platinum thermometer for research work is the endless variety of forms in which it may be made, to suit the particular exigencies of each individual experiment. It is peculiarly suited for observing the average temperature throughout a length or space, which is so often required in physical experiments. For this purpose the wire may be disposed in a straight length, or in a spiral, along the space in question. Again, in observing the temperature of a gas, the naked wire, on account of its small mass and extremely low radiative power, is far superior to any mercury thermometer. The commonest form of platinum thermometer, and the most suitable for general purposes, contains a coil from ½ inch to 2 inches long, wound on a cross of thin mica, and enclosed in a tube, about ¼ to ½ inch in diameter, of glass or porcelain according to the temperature for which it is required. The pyrometer leads and the compensator leads are insulated and kept in place by passing through mica discs fitting the tube, which serve also to prevent convection currents up and down the tube. For temperatures above 1000° C. biscuit porcelain presents certain advantages over mica in strength and infusibility. For the highest temperatures it is proposed to use silica tubes and silica frames, which have been successfully constructed and possess the advantage of being tougher than porcelain. The chief objections to porcelain tubes arise from the glaze, which melts at 1100° C., and is liable to stick to and injure the coils.

It would not be within the scope of the present article to attempt to describe the many ingenious varieties of electrical thermometers which have been devised for special purposes. It would also be impossible to discuss the many other methods of thermometry or pyrometry, depending on expansion, on fusion, on calorimetry, or on radiation. These methods have many useful applications, but are not in general suited for work of precision. It has been thought desirable to restrict the discussion to the most accurate types, because they are the most important for the advancement of science, and could not be adequately treated in a smaller compass. Moreover, descriptions of the commoner methods can be found in many familiar text-books, whereas thermometry of precision is a more recent development, of which no complete exposition is to be found in any English work at the present time. On mercurial and gas thermometry the best treatise is that of Guillaume (*Thermométrie de Précision*, Paris), already referred to. On pyrometry there is a valuable report by Barus, Physical Congress, Paris, 1900; also a recent work by Chatelier and Boudouard (*Mesure des Températures Élevées*, Paris), which is concerned chiefly with the thermocouple, but is well illustrated and up to date. The electrical resistance method as applied to work of precision is to be found only in a series of papers, the most important of which have been referred to.

Alphabetical Index of Symbols.

a, b = Numerical constants in expansion formulæ (18).
C = Coefficient of thermodynamical correction formulæ (25).
c = Co-aggregation volume in formula (19).
f = Fundamental coefficient of expansion of bulb.
M = Mass of gas in bulb of gas thermometer.
p = Pressure of gas in bulb of gas thermometer.
R = Constant of gas thermometer, or resistance of platinum thermometer.

r = Ratio of dead space to volume of bulb.
T = Temperature by gas thermometer.
t = Temperature on the Centigrade scale.
θ = Temperature on the thermodynamical scale.
v = Specific volume of gas.
V = Volume of bulb of gas thermometer.
W = Weight of mercury filling bulb at 0° C.
w = Weight of mercury in overflow. (H. L. C.)

Thibaw, called by the Shans, and officially, Hsipaw, and also frequently Ong Pawng (the name of an old capital), is one of the northern Shan States of Burma. It includes four states—Thibaw, the main state, and the sub-states of Mong Lông, Möng Tung, and Thonzè (or Hsumhsai). The whole state has an estimated area of 4524 square miles, and the population in 1897 was calculated to be 73,248. There were 96 circles, 1260 villages, and 19,436 households. The main state lies on the geological fault which runs east and west across the Shan States, from the Salween at Kun Lông and beyond to nearly the rim of the Shan tableland at Gôkteik. It is therefore broken up into a mass of not very well defined ridges and spurs, crossing and re-entering. The chief plain land is in the valley of the Nam Tu (Myit-ngè), near Thibaw town, and the valley or strath of the Pyawng Kawng, Nawng Ping neighbourhood. Elsewhere the valleys are insignificant. The hills on the Möng Tung border reach their highest elevations in the peaks Loi Pan (6848 feet) and Loi Htan (6270 feet). To the north-west of Thibaw town, on the Tawng Peng border, Loi Lam rises to 6486 feet. The valley of the Nam Tu marks the lowest point in the state at Thibaw town, about 1400 feet, and rises on the east in Möng Tung to a plain level of about 2500 feet, and on the west in Möng Lông to a confused mass of hills with an average height of 4500 feet, broken up by the Nam Yawn and Nam Kaw valleys, which are about 3000 feet above mean sea-level.

The chief river is the Nam Tu or Myit-ngè, also frequently called by its classical name the Dôktawadi. The main stream rises in the Salween–Irrawaddy watershed, and is enlarged by considerable tributaries. At Thibaw town it is 250 yards wide and about 8 feet deep, with a fairly strong current. The Nam Tu is navigable only in local stretches, and between Thonzè and Lawksawk (Yatsauk) it flows through a gorge between cliffs three to four thousand feet high. At the gorge of Hokùt (Ngôkteik) the Nam Htang and the Nam Pasè unite to form the Nam Kut, which passes into the ground at the natural bridge where the Mandalay–Kun Lông railway crosses the gorge, and reappears to join the Nam Tu. The bed of the Nam Kut is about 1500 feet below the general level of the country. Coal is found at various places in the state, but is not of very high quality. Salt-wells are worked by the inhabitants of Mawhkio (Bawgyo) about 7 miles from Thibaw town. The average maximum temperature at the beginning of April is about 96°, and the minimum about the same period 65°. The rainfall averages about 70 inches for the year. The chief crops are rice, cotton, sesamum, tea in the hills, and *thanat*, the leaf of a tree used for the wrapper of the Burma, or "green" cheroot. Cotton cloth was formerly much more generally manufactured than it now is, and a coarse country paper is also made. Other industries are merely of articles for local use. The Government cart road to Lashio passes through the centre of the state, and from this various unmetalled cart roads radiate to different parts of the state and the neighbouring states. The Mandalay–Kun Lông railway under construction will also pass through the capital. Teak forests exist along the banks of the Nam Tu and in the Möng Lông states, but both have been practically exhausted, and will have to be closed for many years. Previous to the annexation, and in a general way still, the state is administered by the *sawbwa*, or chief, aided by a council of six *amats* or ministers. Under them are a number of *nè-baings*, who are in charge of circles and townships. Each *nè-baing* has an *asiyin*, or clerk, and each village has a headman, or *kin-man*. The *amats* supervise the administration of a certain number of districts. The old system is now being assimilated to that followed in Burma. The revenue in 1897–98 amounted to Rs.262,906, and the expenditure in the same year to Rs.221,127.

Thomar, a town of the district of Santarem, Portugal, 12 miles north-east of Lisbon. It is chiefly famous for the magnificent convent of the Order of Christ, founded by the Templar Knight Gualdim Paes, and greatly favoured by King Manuel; the windows of the chapter-house are especially noteworthy. Other interesting edifices are the church of St John the Baptist and the ruins of the Templars' Castle. Paper and cottons are manufactured. Population (1890), 5816; (1900), 6933.

Thomas, Arthur Goring (1850–1892), English musical composer, was the youngest son of Freeman Thomas and Amelia, daughter of Colonel Thomas Frederick. He was born at Ratton Park, Sussex, 20th November 1850, and educated at Haileybury College. He was intended for the Civil Service, but delicate health interfered with his studies, and in 1873 he went to Paris to cultivate the musical talent he had displayed from an early age. Here he studied for two years with Émile Durand. In 1875 he returned to England, and in 1877 entered the Royal Academy of Music, where for three years he studied under Ebenezer Prout and Arthur Sullivan, winning twice the Lucas medal for composition. At a later period he received some instruction in orchestration from Max Bruch. His first published composition was a song, "Le Roi Henri," which appeared in 1871. An early comic opera, *Don Braggadocio* (libretto by his brother, C. I. Thomas), was apparently unfinished; some of the music in it was afterwards used for the *The Golden Web*. A selection from his second opera, *The Light of the Harem* (libretto by Clifford Harrison), was performed at the Royal Academy of Music, 7th November 1879, with such success that Carl Rosa commissioned him to write *Esmeralda* (libretto by T. Marzials and A. Randegger), which was produced at Drury Lane, 26th March 1883. Two years later it was given (in German) at Cologne and Hamburg, and in 1890 (in French) at Covent Garden. On 16th April 1885 Rosa produced at Drury Lane Thomas's fourth and best opera, *Nadeshda* (libretto by Julian Sturgis), a German version of which was given at Breslau in 1890. A fifth opera, *The Golden Web* (libretto by F. Corder and B. C. Stephenson), slighter than its predecessors, was produced (after the composer's death) at Liverpool, 15th February, and at the Lyric Theatre, London, 11th March 1893. Besides these dramatic works Thomas's chief compositions were a psalm, "Out of the Deep," for soprano solo and chorus (London, 1878); a choral ode, "The Sun Worshippers" (Norwich, 1881), and a suite de ballet for orchestra (Cambridge, 1887). A cantata, *The Swan and the Skylark*, was found in pianoforte score among his MSS. after his death: it was orchestrated by C. Villiers Stanford, and produced at the Birmingham Festival of 1894. His minor compositions include over 100 songs and duets. In 1891 Thomas became engaged to be married; shortly afterwards he showed signs of mental disease, and his career came to a tragic end on 20th March 1892. He was buried in Finchley cemetery. Thomas will always occupy a distinct place among English composers of the 19th century. His music shows traces of his early French training, but he possessed a great talent for dramatic composition and a real gift of refined and beautiful melody. He was most critical of his own work, never attempting anything for which he felt he was unfitted, and constantly revising and rewriting his compositions. Personally he was the most amiable of men: the esteem in which he was held was shown by the concert given at St James's Hall after his death with the object of founding a scholarship in his memory, at which there appeared all the chief musicians then in London, both British and foreign. (W. B. S*.)

Thomas, Charles Louis Ambroise (1811–1896), French musical composer, was born at Metz, 5th August 1811. He studied at the Paris Conservatoire,

and won the Grand Prix de Rome in 1832. Five years later, in 1837, his first opera, *La Double Échelle*, was produced at the Opéra Comique. For the next five-and-twenty years Thomas's productivity was incessant, and most of his operatic works belonging to this period enjoyed an ephemeral popularity. A few of these have survived, and are still occasionally heard on the Continent, their names being *Le Caïd* (1849), *Le Songe d'une Nuit d'Été* (1850), *Psyché* (1857). The overture to *Raymond* (1851) has remained popular. So far the composer's operatic career had not been marked by any overwhelming success. He occupied a place among the recognized purveyors of operas in the French capital, but could scarcely claim to having achieved European renown. The production of *Mignon* at the Opéra Comique in 1866, however, at once raised Ambroise Thomas to the position of one of the foremost French composers. Goethe's touching tale had very happily inspired the musician; Madame Galli Marié, the original interpreter of the title-rôle, had modelled her conception of the part upon the well-known picture by Ary Scheffer, and *Mignon* at once took the fancy of the public, its success being repeated all over the Continent. It has since remained one of the most popular operas belonging to the second half of the 19th century. Thomas now attempted to turn Shakespeare's *Hamlet* to operatic account. His opera of that name was produced with success at the Paris Opéra in 1868, where it enjoyed a long vogue. If the music is scarcely adequate to the subject, it nevertheless contains some of the composer's best work. The scene of the esplanade is genuinely dramatic, the part of Ophelia is poetically conceived, and the ballet music is very brilliant. Ambroise Thomas's last opera, *Françoise de Rimini*, was given at the Opéra in 1882, but has not maintained itself in the *répertoire*. Seven years later *La Tempête*, a ballet founded on Shakespeare, was produced at the same theatre. Ambroise Thomas succeeded Auber as director of the Paris Conservatoire in 1871. If it can be said that the talent of Thomas was in its nature rather assimilative, and that it successively yielded to the various influences of the moment, yet it must be allowed that the composer of *Mignon* was not altogether devoid of personality. His music is often distinguished by refined touches which reveal a sensitive mind, and there is a distinct element of poetry in his *Mignon* and *Hamlet*, two operas that should suffice to keep the composer's memory green for some time to come. He died on the 12th of February 1896. (A. HE.)

Thomas, George Henry (1816 – 1870), American soldier, was born in Southampton county, Virginia, 31st July 1816. He graduated from West Point in 1840, and served continuously in the army until his death in 1870, occupying every rank from second lieutenant to major-general. As a young officer of artillery he served in the war against the Seminole Indians in Florida (1841), and in the Mexican war at the battles of Fort Brown, Resaca de la Palma, Monterey, and Buena Vista, receiving three brevets for distinguished gallantry in action. In 1855 he was appointed by Jefferson Davis, then Secretary of War, junior major of the 2nd Cavalry, of which Johnston (A. S.) was colonel, Lee was lieut.-colonel, and Hardee was senior major. At the outbreak of the Civil War these three officers resigned and joined the Confederate States. Thomas was in doubt as to what his duty required, but finally decided to adhere to the United States. He was promoted in rapid succession to be lieut.-colonel and colonel in the regular army, and brigadier-general of volunteers. In command of an independent force in eastern Kentucky, on 19th January 1862, he attacked the Confederate General Zollicoffer at Mill Springs and completely routed him, gaining the first Union victory in the west. In command of an army corps, under General Buell, he was engaged in the battles of Perryville and Stone River. Under Rosecrans, at the battle of Chickamauga, 19th September 1863, he achieved great distinction, his firmness on that disastrous field, where he gained the name of "The Rock of Chickamauga," being all that saved a terrible defeat from becoming a hopeless rout. He succeeded Rosecrans in command of the army of the Cumberland. At Chattanooga, 25th November 1863, in many respects the most brilliant battle of the war, Thomas played a most conspicuous part, his divisions under Sheridan, Wood, and Baird carrying Missionary Ridge in superb style. In Sherman's advance through Georgia in the spring of 1864, Thomas commanded the army of the Cumberland, consisting of three army corps, and numbering over 60,000 men present for duty. Thomas handled these with great skill in all the engagements and flanking movements from Chattanooga to Atlanta. When Hood broke away from Atlanta in the autumn of 1864, menaced Sherman's long line of communications and endeavoured to force Sherman to follow him, Sherman determined to abandon his communications and march to the sea, leaving to Thomas the difficult task of taking care of Hood. Thomas hastened back with a comparatively small force, racing with Hood to reach Nashville where he was to receive reinforcements. At the battle of Franklin, 30th November 1864, a large part of Thomas's force, under command of Schofield, checked Hood long enough to effect a concentration at Nashville. Here Thomas had to organize his force, which consisted largely of quartermaster's employés and improvised troops. He declined to attack until his army was ready and the ice which covered the ground had melted sufficiently to enable his men to move. Grant was impatient of the delay. He sent Logan with an order to supersede Thomas, and soon afterwards left the army of the Potomac to take command in person. Before either arrived Thomas made his attack, 15th and 16th December 1864, and inflicted on Hood a most crushing defeat, so absolute and complete that Hood's army never again appeared as a factor in the Civil War. For this brilliant victory Thomas was made a major-general in the regular army, and received the thanks of Congress. After the termination of the Civil War he served on reconstruction duty in command of military departments in Kentucky and Tennessee until 1869, when he was ordered to command the division of the Pacific with headquarters at San Francisco. He died there of apoplexy, while writing an answer to an article criticizing his military career, 28th March 1870.

Thomas was beloved by his soldiers, for whom he always had a fatherly solicitude. He was a man of solid rather than brilliant attainments: he remained in the army all his life, and never had any ambitions outside of it; his mind acted deliberately, and his temperament was somewhat sluggish; but his judgment was remarkably accurate, his knowledge of his profession was complete in every detail, and when he had finally grasped a problem, and the time arrived for action, he could strike with extraordinary vigour and rapidity. The only two battles in which he had no immediate superior—Mill Springs and Nashville, one at the beginning and the other at the end of the war—were signal victories, without defect and above criticism. His service during the intervening three years of almost incessant conflict and manœuvring was marked by loyal obedience to his

superiors, skilful command of his subordinates, and successful accomplishment of every task entrusted to him. (F. V. G.)

Thomas, Theodore (1835– ——), American musician, was born in Esens, Germany, 11th October 1835. His early musical training was received chiefly from his father. His career began early, for at the age of six he made his first public appearance as a violinist. Four years later he was taken to America by his parents, and when only fifteen years old (1850) was first violin in the orchestra that accompanied Jenny Lind in her American tour. From 1855 to 1869 he took part in a series of chamber music concerts in New York. In 1867 he organized the Thomas Orchestra, and it is in the capacity of orchestra conductor that he made his reputation. His orchestra made its first tour in 1869, and continued to give concerts in various American cities until it was disbanded in 1888. During most of the seasons from 1877 to 1891 he was conductor of the New York Philharmonic Society, and from 1862 to 1891, of the Brooklyn Philharmonic Society. He was director of the Cincinnati College of Music, 1878–81, conductor of the American Opera Company, 1885–87, and for a quarter of a century (1873–98) the conductor of the biennial May festivals at Cincinnati. In 1891 he removed to Chicago, and was subsequently the conductor of the Chicago Orchestra. In 1893 he was musical director of the Columbian Exposition in that city. His ability as a conductor has had an important influence in the elevation of public taste for music in America.

Thomasville, a city of Georgia, U.S.A., capital of Thomas county, in the southern part of the state, on a line of the Plant Railway system, and on the Tifton, Thomasville, and Gulf Railway, at an altitude of 250 feet. It is known as a winter resort for Northern people. The surrounding country produces much cotton and early vegetables and fruit, the latter being raised mainly for Northern markets. Population (1880), 2555; (1890), 5514; (1900), 5322, of whom 69 were foreign-born and 3296 negroes.

Thompson, a town of Windham county, Connecticut, U.S.A., with an area of 50 square miles of hill country, traversed by French river, and by a line of the New York, New Haven, and Hartford Railroad, in the north-eastern part of the state. It contains several villages, among which are Thompson, West Thompson, Mechanicsville, Grosvenordale, North Grosvenordale, and Quinebaug. Population (1880), 5051; (1890), 5580; (1900), 6442, of whom 2914 were foreign-born.

Thompson, Sir Henry, Bart. (1820– ——), English surgeon, was born at Framlingham, Suffolk, on the 6th of August 1820. His father wished him to enter business, but circumstances ultimately enabled him to follow his own desire of becoming a physician, and in 1848 he entered the medical school of University College, London. There he had a brilliant career, and obtained his degree at London University in 1851 with the highest honours in anatomy and surgery. In 1853 he was appointed assistant surgeon at University College Hospital, becoming full surgeon in 1863, professor of clinical surgery in 1866, and consulting surgeon in 1874. In 1884 he became professor of surgery and pathology in the Royal College of Surgeons, which in 1852 had awarded him the Jacksonian prize for an essay on the *Pathology and Treatment of Stricture of the Urethra*, and again in 1860 for another on the *Health and Morbid Anatomy of the Prostate Gland*. These two memoirs indicate the department of medical practice to which he devoted his main attention. Specializing in the surgery of the genito-urinary tract, and in particular in that of the bladder, he went to Paris to study under Civiale, who in the first quarter of the 19th century proved that it is possible to crush a stone within the human bladder, and after his return he soon acquired a high reputation as a skilful operator in that class of disease. In 1863, when the King of the Belgians was suffering from stone, he was called to Brussels to consult in the case, and after some difficulties was allowed to perform the operation of lithotrity: this was quite successful, and in recognition of his skill Thompson was appointed surgeon-extraordinary to the king, an appointment which was continued by Leopold II. Nearly ten years later he carried out a similar operation on the Emperor Napoleon, who, however, died four days after the second crushing, not from the surgical interference, as was proved by the post-mortem examination, but from uræmic poisoning. Besides devising various operative improvements in the treatment of the disorders which were his speciality, Sir Henry Thompson wrote various books and papers dealing with them, including *Clinical Lectures on Diseases of the Urinary Organs*, *Practical Lithotomy and Lithotrity*, *Tumours of the Bladder*, *Suprapubic Lithotomy*, and *Preventive Treatment of Calculous Disease*. Among other books of a medical character that came from his pen were *Food and Feeding*, and *Diet in Relation to Age and Activity*, both of which passed through a number of editions. In 1874 he took a foremost part in founding the Cremation Society of England, of which he was the first president; and not only was he active in urging the advantages of cremation as a means of disposing of the body after death, but also did much towards the removal of the legal restrictions by which it was at first sought to prevent its practice in England. On various occasions he denounced the slackness and inefficiency of the methods of death-certification prevalent in Great Britain, and in 1892 his agitation was instrumental in procuring the appointment of a Select Committee to inquire into the matter; its report, published in the following year, in great measure confirmed his criticisms and approved the remedies he suggested. But medicine and hygiene by no means exhaust the list of Sir Henry Thompson's activities. In art he is an accomplished sketcher, and, moreover, an amateur of painting whose pictures have been hung at the Royal Academy and the Paris Salon. About 1870 he began to get together his famous collection of china, in particular of old blue and white Nanking; this in time became so large that he could no longer find room for it, and most of it was sold. A catalogue of it, illustrated by himself and Mr James Whistler, was published in 1878. In his famous octaves he may be said to have elevated the giving of dinner parties into a fine art. The number of courses and of guests was alike eight, and both were selected with the utmost care and discrimination to promote the "feast of reason and the flow of soul." In literature, in addition to more serious works, he produced two novels—*Charley Kingston's Aunt* (1885) and *All But* (1886)—which met with considerable success. In science he became a devotee of astronomy, and for a time maintained a private observatory in his house at Molesey. He further did much to promote astronomical study in Great Britain by presenting Greenwich Observatory with some of the finest instruments now among its equipment, his gifts including a photoheliograph of 9-inch aperture, a 30-inch reflecting telescope, and a large refracting telescope having an object-glass of 26 inches diameter and a focal length of 22½ feet. The offer of the last instrument was made in 1894. Its manufacture was undertaken by Sir Howard Grubb of Dublin, and its erection was

completed in 1897. It added greatly to the instrumental resources of Greenwich, especially for photographic work, and its importance may be gauged from the fact that both in aperture and focal length it is double the size of any instrument possessed by the observatory at the time it was put in place. That Sir Henry Thompson, who was knighted in 1867, received a baronetcy in 1899 was probably not unconnected with the presentation of this telescope to the national observatory.

Thomsen, Grímur (1820–1896), Icelandic poet and man of letters, was born in 1820. He came in 1837 to the University of Copenhagen, where he first studied law and philology, but later, philosophy and æsthetics. He became an enthusiastic follower of the Pan-Scandinavian movement, although this was not generally favoured by his countrymen. After some years of foreign travel, in 1848 he entered the Danish diplomatic service, and remained in it till 1851, when he returned to Copenhagen, where he became the chief of one of the departments of the Danish Foreign Office. He retired in 1866, and then went back to Iceland, where he passed the rest of his life, active in the politics and the literature of his native island. He died in 1896. He is the best ballad poet Iceland has produced. His poems are unaffected and mostly free from rhetoric, the besetting sin of Icelandic poets. His subjects are principally taken from Icelandic or Scandinavian history and mythology. He is very unlike most of his contemporaries, both in style and thought: he is Icelandic to the core, and on that account is perhaps the modern Icelandic poet most appreciated by foreigners. Besides his poems (two separate collections, Reykjavík, 1880, and Copenhagen, 1895), he is the author of numerous critical and historical essays in Icelandic and Danish, and some larger works in Danish, of which his dissertation on Lord Byron (Copenhagen, 1845) deserves to be mentioned. Grímur Thomsen was a warm admirer of Greek literature, and translated a great number of poems from that language into Icelandic. (S. BL.)

Thomson, James (1822–1892), British physicist and engineer, was born in Belfast on the 16th of February 1822, and, like his younger brother, Lord Kelvin, at an unusually early age began to attend the classes at Glasgow University, where his father had been appointed professor of mathematics in 1832. After his graduation he decided to study civil engineering, and for that purpose became a pupil in several engineering offices and works successively; but ill-health obliged him to leave them all, and he had finally to accept the fact that an occupation involving physical exertion was out of the question. Accordingly, from about 1843, he devoted himself to theoretical work and to mechanical invention. To this period belong his well-known researches in thermodynamics, which enabled him to predict by the application of Carnot's theorem that the temperature of the freezing-point of substances which expand on solidifying must be lowered by the application of pressure, the reverse being the case with substances which contract on solidification; and he was able to calculate the amount by which a given pressure lowers the freezing-point of water, a substance which expands on solidification. His results were experimentally verified in the physical laboratories of Glasgow University under Lord Kelvin's direction, and were afterwards applied to give the explanation of regelation which is now generally accepted. In 1861 he extended them in a paper on crystallization and liquefaction as influenced by stresses tending to change of form in crystals, and in other studies on the change of state he continued Andrews's work on the liquid and gaseous states of matter, constructing a thermodynamic model in three dimensions to show the relations of pressure, volume, and temperature in a substance like carbonic acid. With regard to his inventions, he devised a clever feathering mechanism for the paddles of steamboats when only a boy of sixteen, and later turned his attention to water engines. In 1850 he patented his "vortex water-wheel," and during the next three or four years carried on inquiries into the properties of "whirling fluids," which resulted in improved forms of blowing-fans and water-turbines and in the invention of a centrifugal pump. Settling in Belfast in 1851, he was selected to be the resident engineer to the Belfast Water Commissioners in 1853, and four years later became professor of civil engineering and surveying in Queen's College, Belfast. Thence he removed in 1873 to Glasgow as successor to Macquorn Rankine in the chair of engineering in the university, and retained this position until 1889, when the failure of his eyesight compelled him to resign. He died on the 8th of May 1892. Among other subjects which he worked at, in addition to those already mentioned, were the explanation of the parallel roads of Glen Roy and of the prismatic structure seen at the Giant's Causeway; the flow of water in rivers, in which, during 1876 and following years, he studied the origin of windings in alluvial plains and made many experiments with the aid of artificial rivers; and the currents of atmospheric circulation, which afforded him the material for the Bakerian lecture of 1892.

Thomson, Joseph (1858–1895), African explorer, was born on 14th February 1858 at Penpont, Dumfriesshire. In 1868 the family removed to Gatelawbridge, where young Thomson was soon attracted by the natural curiosities and historical associations of Nithsdale. In 1875 he went to Edinburgh University, where he paid particular attention to geology and botany, and after completing his course in 1878 he was appointed geologist and naturalist to the Royal Geographical Society's expedition to East Central Africa under Keith Johnston. The latter died at Behobeho, between the coast and the north end of Lake Nyasa, 28th June 1879, and Thomson then took command. Though very young, his coolness and tact were remarkable, and he successfully conducted the expedition across the desolate region of Uhehè and Ubena to Nyasa, and then by a hitherto unexplored track to Lake Tanganyika, where he settled the moot question of the Lukuga outlet. After enduring terrible hardships among the Warua, he returned through Bagamoyo, reaching London in August 1880. In the following year he published an account of his travels, under the title *To the Central African Lakes and Back*. About this time the sultan of Zanzibar, being anxious to develop certain supposed coal-beds on the river Rovuma, was advised to obtain independent expert opinion as to their value. Application was made to Thomson, who undertook to survey them, and started from Mikindani, 17th July 1881. The coal, however, turned out to be merely bituminous shale, and Thomson, on his return to Zanzibar, had to endure much delay and vexation through the sultan's chagrin. For a considerable time the explorer had directed his attention to Masai-land, that wild region occupied by a powerful tribe of intractable savages, and Gordon had already pointed out that the true route to the head-waters of the Nile lay through that territory. In 1882 the Royal Geographical Society took up the question, and requested Thomson to report on the practicability of taking a caravan through the Masai country, which no European had yet been able to penetrate beyond Mount Kilimanjaro. By undaunted courage and great resourcefulness he succeeded in crossing the Njiri desert and exploring the great Rift Valley.

Thence he went with a picked company through Lykipia to Mount Kenia, emerged on Lake Baringo, and shortly afterwards traversed the unknown region lying between this lake and Victoria Nyanza. The account of this adventurous journey appeared in 1884, under the title of *Through Masai-land*, and it is a classic in modern travel. The hardships and anxieties attendant on such a career now began to tell upon Thomson's exceptionally hardy constitution, but he undertook an expedition to the Niger for the National African (afterwards the Royal Niger) Company, and succeeded by his energy in concluding valuable commercial treaties with the sultans of Sokoto and Gandu. In 1888, by way of recreation, he travelled through southern Morocco and explored a portion of the Atlas range, and published the results in the following year, under the title *Travels in the Atlas and Southern Morocco*. Twice again he visited Africa, proceeding in 1890–91 to the Zambezi for the British South Africa Company, on which occasion he met Mr Rhodes; and again in 1893 to South Africa, this time in search of health. His journey in 1890–91 had proved disastrous to a constitution already undermined, and after a short sojourn he returned to London, where he died on 2nd August 1895. The accounts of his minor travels were published in magazines or in the *Proceedings of the Royal Geographical Society*. "Thomson was endowed with a special genius for the observation of the natural features of a country. His methods of dealing with aborigines were so gentle and persuasive that his expeditions never had recourse to arms, and he covered so much unknown ground that he will probably remain the last great geographical pioneer of African exploration." (G. F. B.)

Thomson, William (1819–1890), English divine and logician, was born on 11th February 1819 at Whitehaven, in Cumberland. He was sent to Shrewsbury School, whence he proceeded to Queen's College, Oxford, of which he became a scholar. He took his B.A. degree in 1840, and was soon afterwards made fellow of his college. He was ordained in 1842, and worked as a curate at Cuddesdon, under the eye of the then bishop of Oxford. In 1847 he was made tutor of his college, and in 1853 he delivered the Bampton Lectures, his subject being "The Atoning Work of Christ viewed in Relation to some Ancient Theories." These lectures established his reputation, being thoughtful and learned, and they did much to clear the ground for the subsequent discussions on the doctrine of the Atonement, with which theologians are familiar. But Dr Thomson's activity was not confined to theology. He was made fellow of the Royal and the Royal Geographical Societies. He was examiner in logic and mental science for the Society of Arts. He wrote a treatise on *Pure and Applied Logic*, which immediately became popular, and soon reached a second edition. He sided with the party at Oxford which favoured University reform, but this did not prevent him from being appointed president of his college when the post became vacant in 1855. In 1858 he was made preacher at Lincoln's Inn, and there preached some striking sermons, a volume of which he published in 1861. In the same year he edited *Aids to Faith*, a volume written by eminent divines in opposition to the famous *Essays and Reviews*, which, with its advanced liberal sentiments, had stirred up a great storm in the Church of England. In December of that year, in recognition of the services he had rendered to the cause of orthodoxy in the Church, he was appointed to the see of Gloucester and Bristol, which had become vacant, and within a twelvemonth he was elevated to the archiepiscopal see of York. In this position Dr Thomson, whose orthodoxy was of what may be called the Moderate type, excited the fierce indignation of the High Church party by the support he gave to the passing of the Public Worship Regulation Act, and, as president of the Northern Convocation, he came frequently into sharp collision with the Lower House of that body. But if he incurred the hostility of the High Church party among the clergy, he was admired by the laity for his strong sense, his clear and forcible reasoning, and his wide knowledge, and he remained to the last a power in the north of England. In his later years he published an address read before the members of the Edinburgh Philosophical Institution (1868), one on *Design in Nature*, for the Christian Evidence Society, which reached a fifth edition, various charges and pastoral addresses, and he was one of the projectors of *The Speaker's Commentary*. He died on 25th December 1890. (J. J. L*.)

Thôngwa, a district in the Irrawaddy division of Lower Burma. It was formerly in the Pegu division, and contained 5413 square miles. Increase of population and of cultivation, however, led to its reduction in size, and a portion was taken from it in 1896 to form the district of Myaungmya. In 1898–99 the district had an area of 3470 square miles, and a population (1891) of 333,443; (1901), 482,680. The revenue paid in 1898–1899 by 971 villages was Rs.30,64,920. The population was made up in 1891 of 316,841 Buddhists and Jains, 3508 Hindus, 2769 Mahommedans, 1073 aborigines (mostly Karens), and 9252 Christians, of whom 8954 were natives (mostly Karens). Of a total acreage of 2,220,800, there were 788,065 acres cultivated in 1898–99; 651,918 acres were not available for cultivation; 34,560 acres were under forest; 685,577 acres were cultivable; and there were 60,680 acres of current fallow. The rainfall in 1898–99, taken at Maubin, was 96·67 inches. Yandoon (20,235 inhabitants) and Maubin (5327) were the chief towns. Maubin is the headquarters of the district, and has been a municipal town since 1888, with fifteen of a committee, eleven of whom are elective. The steamers of the Irrawaddy Flotilla Company call at Maubin and Yandoon.

Thorbecke, Jan Rudolf (1798–1872), Dutch statesman, was born at Zwolle, in the province of Overijssel, 14th January 1798. Thorbecke was of German extraction, his grandfather, Heinrich Thorbecke, having settled in Overijssel towards the end of the 17th century. Little is known of his youth, beyond the fact that he was sent in the year of Waterloo to Amsterdam for his education. For two years he stayed with a Lutheran clergyman of the name of Sartorius, whilst attending the lectures of the Athenæum Illustre. In 1817 he commenced his studies at Leyden University, proving a brilliant scholar, and twice obtaining a gold medal for his prize essays. In 1820 he obtained the degrees of Lit.D. and LL.D. In the following years Thorbecke undertook a journey of research and study in Germany, staying at most of her famous universities, and making the acquaintance of his best-known contemporaries in the Fatherland. At Giessen he lectured as an extraordinary professor, and at Göttingen, in 1824, published his treatise, *Ueber das Wesen der Geschichte*. After his return to Amsterdam in 1824 Thorbecke wrote his first political work of any importance, *Bedenkingen aangaande het Recht en den Staat* ("Objections anent Law and the State"), which by its close reasoning and its legal acumen at once drew attention to the young barrister, and procured him in 1825 a chair as professor in Ghent University. Here he wrote two pamphlets of an educational character before 1830. The Belgian revolt of that year forced

Thorbecke to resign his position at Ghent, and he subsequently went to Leyden. He did not approve of the Belgian movement, nor of the part that Europe played in it, and published his views in three pamphlets, which appeared in the years 1830 and 1831. In 1831 he was appointed professor of jurisprudence and political science at Leyden University. In that capacity, and, before his appointment at Leyden, as a lecturer on political science, history, and economics at Amsterdam, he gained great reputation as a political reformer, particularly after the publication of his standard work, *Aanteekeningen op de Grondwet* ("Annotations on the Constitution" 1839; second edition, Amsterdam, 1841–43), which became the text-book and the groundwork for the new Reform Party in Holland, as whose leader Thorbecke was definitively recognized. Thorbecke's political career until his death, which occurred at The Hague, 4th June 1872, has been sketched under HOLLAND: *History*. Thorbecke's speeches in the Dutch Legislature were published at Deventer in six volumes (1867–1870), to which should be added a collection of his unpublished speeches, printed at Groningen in 1900. The first edition of his *Historische Schetsen* ("Historical Essays") was issued in 1860, the second in 1872. At Amsterdam there appeared in 1873 a highly interesting *Correspondence* with his academy friend and lifelong political adversary Groen Van Prinsterer (*q.v.*), which, although dating back to the early 'thirties, throws much light on their subsequent relations and the political events that followed 1848. Of Dutch statesmen during the Napoleonic period, Thorbecke admired Falck and Van Hogendorp most, whose principles he strove to emulate. Of Van Hogendorp's *Essays* and *Speeches*, indeed, he published a standard edition, which is still highly valued. Thorbecke's speeches form a remarkable continuation of Van Hogendorp's orations, not only in their style, but also in their train of thought. Thorbecke's funeral furnished the occasion for an imposing national demonstration, which showed how deeply he was revered by all classes of his countrymen. In 1876 a statue of Thorbecke was unveiled in one of the squares of Amsterdam.

Thorbecke's gifts and public services as a statesman have been as fully recognized as his political genius has been. As an orator and writer his style was clear and forcible. His very dogmatism brought him many enemies, but at times, especially when he went in advance of his time, he was a much misunderstood man. These misunderstandings, frequently wilful, extended often beyond the domain of pure politics. Thus, by his enemies Thorbecke was often held up to scorn as a pure materialist, and no friend of the fine arts, because at a sitting of the States General in 1862 he had said that it is not the duty of the State, nor in the true interest of art itself, for the Government to "protect" art, since all State-aided art must be artificial, like any forced plant. This was popularly condensed into the aphorism, yet current in Holland, that "Art is not the business of the Government," and Thorbecke was condemned as the author of it. Again, his adversaries used to call him a dangerous demagogue. As a matter of fact, there was no more ardent royalist than Thorbecke. He believed in constitutional monarchy, as offering the best guarantees both for sovereign and people, and he was bitterly opposed to all forms of State Socialism. Long before his death he realized that he had outlived his own principles, and many of his former admirers had commenced to dub him a "rank Conservative," whose political aims and reforms were no longer adequate. But Thorbecke's life-work will endure, and the Dutch Constitution of 1887 practically embodied his principles, as laid down in the Constitution of 1848. The former is the outcome of the latter, and could not have been made without it.

The best biographical sketch of Thorbecke we owe to the late Professor Buys, his principal scholar and devoted friend, whose biography appeared in 1876 at Tiel. Another biography which deserves mention was issued in the same year at The Hague, from the pen of Dr J. A. Levy, an Amsterdam lawyer. (H. TI.)

Thorn, a fortified town of Prussia, province of West Prussia, on the right bank of the Vistula, 87 miles by rail north-east of Posen. The new garrison church (1897), the church of St James's (1309), a good specimen (in Gothic brick) of the architecture of the Teutonic Knights; the Junkerhof, restored in 1883; the Copernicus monument (1853), the municipal museum in the town hall, and the synagogue are the chief architectural features. Population (1885), 23,906; (1895), 30,314; (1900), 29,626.

Thornaby-on-Tees, a municipal borough and railway station in the Cleveland parliamentary division of the North Riding of Yorkshire, England, opposite Stockton-on-Tees (with which it is connected by a bridge), on the river Tees. The town was formerly known as South Stockton, and is still included in the parliamentary borough of Stockton, but was incorporated as a separate municipal borough in 1892. In the same year the town hall was completed. There are blast furnaces, iron foundries, engineering works, iron shipbuilding yards, extensive saw-mills, flour-mills, and a manufacture of "blue and white" pottery. Population (1881), 10,852; (1891), 15,637; (1901), 16,053.

Thóroddsen, Jón Þórðarson (1819–1868), Icelandic poet and novelist, was born in 1819, at Reykhólar in western Iceland. He studied law at the University of Copenhagen, entered the Danish army as volunteer in 1848 in the war against the insurgents of Schleswig and Holstein, who were aided by Prussia and other German states. He went back to Iceland in 1850, became sheriff (*sýslumaður*) of Barðastrandarsýsla, and later in Borgarfjarðarsýsla, where he died in 1868. He is the first novel-writer of Iceland. Jónas Hallgrímsson had led the way by his short stories, but the earliest veritable Icelandic novel was Jón Thóroddsen's *Piltur og Stúlka* ("Lad and Lass"), a charming picture of Icelandic country life. Still better is *Maður og Kona* ("Man and Wife"), published after his death by the Icelandic Literary Society. He had a great fund of delicate humour, and his novels are so essentially Icelandic in their character, and so true in their descriptions, that he is justly considered by most of his countrymen not only as the father of the Icelandic novel, but as the best novelist Iceland has produced. His poems, mostly satirical, are deservedly popular: he follows Jónas Hallgrímsson closely in his style, although he cannot reach him in lyrical genius. (S. BL.)

Three Rivers, a city and port of entry of Quebec, Canada, at the confluence of the rivers St Maurice and St Lawrence. The principal development of trade has been the result of utilizing the immense water-power of the St Maurice at Shawanegan, Grand Mere, and other falls for the manufacture of wood-pulp. Population (1891), 8334; (1901), 9981.

Thring, Edward (1821–1887), one of the most distinguished schoolmasters of the 19th century, was the son of John Gale Dalton Thring, rector of Alford, Somerset, and was born 19th November 1821. His elder brother was HENRY THRING (born 1818), the distinguished Parliamentary counsel (1868–1886), who was made a peer as Baron Thring in 1886. Edward was educated first at Ilminster grammar school and afterwards at Eton, where

he became head of the school, and Captain of Montem in 1841, the last occasion on which that ancient festival was celebrated. He then entered King's College, Cambridge, won the Porson prize for Greek, and was elected fellow. At that time King's College scholars retained the privilege of proceeding to a degree without examination, but Thring thought the maintenance of this usage inexpedient in the interests of learning and wholly indefensible in principle, and his vigorous protests against it aroused lively academic controversy, and became effective in 1851, when it was abolished. On leaving the university in 1846 he was ordained, and served for a short time as curate in Gloucester. Here he took remarkable interest in the elementary school of the parish, and ever afterwards attributed much of his professional success and his insight into educational principles and methods to the experience he had acquired in imparting the humble rudiments of learning to the children of the poor. After an interval of two or three years, spent partly in private tuition and partly as curate at Cookham Dean, he married in 1853 a daughter of Carl Koch, commissioner of customs at Bonn, and was elected to the mastership of Uppingham School, a post which he retained until his death in 1887. That school had been founded in 1584, was slenderly endowed, poorly housed, and little known. Thring found only twenty-five boys in it, but he succeeded in raising it both in numbers and repute to a position in the first rank among English public schools. He had a strong conviction that there should be a limit to the number of pupils entrusted to the care of one head-master, and he fixed that limit at 300, although, owing to the increasing popularity of the school, he was under strong temptation to exceed it. Little by little he surrounded himself with a loyal staff of masters, raised money for the building and equipment of a noble school-room and chapel, besides class-rooms and eleven boarding-houses. Among the distinctive features of his plans and achievements were: (1) his strong sense of the need for a closer study of the characteristics of individual boys than is generally found possible in large public schools; (2) his resolute adherence to the discipline of the ancient languages, in connexion with English, as the staple of a liberal education; (3) his careful provision of a great variety of additional employments and interests, in studies and in games, to suit the aptitudes of different pupils; (4) the value he attached to the æsthetic side of school training, as evinced in the encouragement he gave to music and to drawing, and to the artistic decoration of the school-rooms; and above all (5) his rebellion against mere routine, and his constant insistence on the moral purpose of a school as a training-ground for character, rather than as a place solely concerning itself with the acquisition of knowledge. The vigour and intrepidity of his character were conspicuously shown in 1875, when an outbreak of fever made Uppingham for a time untenable, and when, at a few days' notice, he took a disused hotel and some boarding-houses at Borth, on the Cardiganshire coast, and transported the whole 300 boys, with 30 masters and their households, to it as to a city of refuge. Here the school was carried on with undiminished and even fresh zest and efficiency for fourteen months, during which needful sanitary measures were taken in the town.

Unlike Arnold, with whose moral earnestness and lofty educational aims he was in strong sympathy, he took little or no part in outside controversies, political or ecclesiastical. All the activity of his life centred round the school. His was the first public school to establish a gymnasium, and the first to found a town mission in a district of South London, with a view to interest the boys in an effort to improve the social condition of the poor. He took the first step in 1869 in the formation of the Head Masters' Conference, an institution which has ever since done much to suggest improvements in method and to cultivate a sense of corporate life and mutual helpfulness among the teachers in the great schools. And in 1887 he took the bold and unprecedented step of inviting the Association of Head Mistresses to Uppingham, and giving to them a sympathetic address. He also formed an association in Uppingham, with lectures, cookery classes, concerts, and other aids to the intellectual and social improvement of the residents of the little town. He gave valuable evidence before the Schools Inquiry Commission of Lord Taunton in 1866, but it was very characteristic of him that he dreaded the intrusion of public authority, whether that of royal commissioners or of the legislature, into the domain of the school, wherein he thought it indispensable that the liberty and personal inventiveness and enthusiasm of teachers should have full scope and be hindered by no official regulations.

His contributions to literature were not numerous, but were all closely connected with his work as a schoolmaster. They were: *Thoughts on Life Science*, 1869, written under the assumed name of Benjamin Place; *Education and School*, 1864; *The Theory and Practice of Teaching*, 1883; *Uppingham School Sermons*, 1858; *The Child's Grammar*, 1852; *The Principles of Grammar*, 1868; *Exercises in Grammatical Analysis*, 1868; *School Songs*, 1858; *Borth Lyrics*, poems and translations, 1887; and a volume of *Miscellaneous Addresses*, published after his death in 1887.

The fullest account of his life is that written by Professor G. R. Parkin of Canada, 1898, containing copious extracts from his diary and letters, *A Memory of Edward Thring;* and *Uppingham by the Sea*, written by J. H. Skrine, the warden of Glenalmond, who was first a pupil and afterwards an assistant master at the school, presents a vivid and attractive picture of Thring's active life, and an affectionate and yet discriminating estimate of his character. Other particulars may be found in the chapter devoted to his biography in Sir Joshua Fitch's *Educational Aims and Methods*, and in *Edward Thring, Teacher and Poet*, by Canon H. D. Rawnsley. (J. G. F.)

Thun - Hohenstein.—The family of Thun-Hohenstein, one of the wealthiest of the Austrian nobility, which has for more than 200 years settled at Tetschen, in Bohemia, has given several distinguished members to the Austrian public service. Of the three sons of Count Franz, the eldest, Friedrich (1810–1881), entered the diplomatic service; after holding other posts he was in 1850 appointed president of the restored German Diet at Frankfurt, where he represented the anti-Prussian policy of Schwarzenberg, and often came into conflict with Bismarck, who was Prussian envoy. He was afterwards ambassador at Berlin and St Petersburg. After his retirement from the public service in 1863 he supported in the Bohemian Landtag and the Austrian Reichsrath the federal policy of his brother Leo. In 1879 he was made hereditary member of the House of Lords. In this position he was on his death succeeded by his eldest son Franz Anton, who was born in 1847. Like the rest of his family, he belonged to the Federalist party, and his appointment in 1889 as governor of Bohemia was the cause of grave dissatisfaction to the German Austrians. He took a leading part in the negotiation of 1890 for the Bohemian settlement, but the elections of 1891, in which the young Czechs who were opposed to the feudal party gained a decisive victory, made his position a very difficult one. Contrary to expectation, he showed great energy in suppressing disorder; but after the proclamation of a state of siege his position became untenable, and in

1895 he had to resign. On the resignation of Badeni in 1898, he was made minister president, an office which he held for little more than a year, for, though he succeeded in bringing to a conclusion the negotiations with Hungary, the support he gave to the Czechs and Slovenians increased the opposition of the Germans to such a degree that parliamentary government became impossible, and at the end of 1899 he was dismissed.

The third son of Count Franz, Leopold or Leo (1811–1888), was one of the leading Austrian statesmen. After studying at the University of Prague, he travelled through Europe, and among other countries he visited England, where he became acquainted with James Hope (afterwards Hope-Scott) and other leaders of the Tractarian party. He was much affected by the romantic movement and the Ultramontane revival, and after his return home interested himself greatly in the revival of Czech language and literature and the growth of the Bohemian national feeling. He formed a personal friendship with Palacky and others of the Czech leaders; he helped in the foundation of schools in which Czech should be taught, and set himself to acquire some knowledge of the language. He was also interested in prison reform, on which he wrote, and other philanthropic work. After serving under Stadion in Galicia, he was in 1848, after the outbreak of the revolution, appointed president of the administration and acting Stadthalter in Bohemia. He had scarcely entered on his duties when the rebellion of June broke out in Prague. In order to avoid bloodshed, he went down to the insurgents on the barricade, but was seized by them, imprisoned, and for some time his life was in danger. On his release he vigorously supported Windischgrätz, who was in command of the troops, in the restoration of order, but thereby lost his popularity and was superseded. He still defended the Bohemian national movement, and in one of his writings laid down the principle that nationality was one of the interests outside the control of the State. Notwithstanding this, in 1849 he accepted the office of minister of religion and education, which he held in 1860 under the autocratic and centralizing administration of Schwarzenberg and Bach. At first he threw himself with great energy into the task of building up an adequate system of schools. He summoned experienced teachers, Protestant as well as Catholic, from Germany, established middle and higher schools in all parts of the empire, superseded the antiquated text-books and methods of instruction, and encouraged the formation of learned societies and the growth of a professional spirit and independence among the teachers. It is noticeable that at this time he insisted on the use of German in all schools of higher education. As minister of religion he was to a certain extent responsible for the concordat which again subjected the schools to the control of the Church: to a certain extent he thereby undid some of his work for the extension of education, and it was of him that Grillparzer said, "I have to announce a suicide. The minister of religion has murdered the minister of education." But during his administration the influence of the Church over the schools was really much less than, by the theory of the concordat, it would have appeared to be. The crisis of 1860, by which the office he held was abolished, was the end of his official career; for the rest of his life he was very prominent as the leader of the Federalist party in Bohemia. His high social position, his influence at Court, his character as well as his undoubted abilities, and learning not often in Austria found in a man of his rank, gave him great influence. He supported the claims of Bohemia to a full autonomy; he strongly attacked both the February constitution and the *ausgleich* with Hungary; what he desired was a common parliament for the whole empire based on a settlement with each one of the territories. With the old Czechs, he refused to recognize the constitution of 1867; he helped to draft the declaration of 1868 and the fundamental articles of 1871, and took a leading part in the negotiations during the ministry of Potocki and Hohenwart. In order to found a strong conservative party, he established a paper, the *Vaterland*, which was the organ of the Clerical and Federalist party. It is needless to say that he protested against the ecclesiastical legislation of 1867 and 1873. He married in 1847 the Countess Clàm-Martinitz, but there was no issue of the marriage.

See the very full article by Frankfurter in the *Allgemeine Deutsche Biographie*, which supersedes his earlier biography.

(J. W. He.)

Thuret, Gustave-Adolphe (1817–1875), French botanist, was born in Paris on 23rd May 1817. He came of an old Huguenot family, which had sought refuge for a time in Holland after the revocation of the Edict of Nantes. A trace of Dutch influence still persists in the pronunciation of the family name, in which the final *t* is sounded. Thuret's mother was brought up in England; English was the first language that he learnt, and he appears to have retained strong sympathies with Great Britain throughout life. As a young man he studied for the law; in his leisure time he was an ardent musician, and it was from a musical friend, de Villers, that he received, in 1837, his first initiation into botany. Beginning simply as a collector, he soon came under the influence of Decaisne, whose pupil he became. It was Decaisne who first encouraged him to undertake those algological studies which were to become the chief work of his life. Thuret twice visited Constantinople in company with the French ambassador, M. de Pontois, and was for a time attaché to the French embassy there. His diplomatic career, though of short duration, gave him a valuable opportunity of studying the Oriental flora. After travelling in Syria and Egypt in the autumn of 1841, he returned to France. Giving up his intention of entering the civil service, he retired to his father's country house at Rentilly, and thenceforth devoted himself to scientific research. He had already, in 1840, published his first scientific paper, "Notes sur l'anthère de *Chara* et les animalcules qu'elle renferme," in which he first accurately described the organs of motion of the "animalcules" or spermatozoids of these plants. He continued his studies of the zoospores and male cells of Algæ and other Cryptogams, and our exact knowledge of these remarkable motile stages in vegetable life is largely due to his labours. He spent a great part of his time, up to 1857, on the Atlantic coast of France, assiduously observing the marine Algæ in their natural habitat and at all seasons. In conjunction with his friend Édouard Bornet, he became the recognized authority on this important group of plants, of which the two colleagues acquired an unrivalled knowledge. Their work, while remarkable for taxonomic accuracy, was more especially concentrated on the natural history, development, and modes of reproduction of the plants investigated. The discovery of sexual reproduction in seaweeds is almost wholly the work of these two men. The researches on the fecundation of the Fucaceæ were published by Thuret in 1853 and 1855; the complicated and difficult question of the sexual reproduction in Florideæ was solved by the joint work of Thuret and Bornet (1867). These great discoveries—of far-reaching biological significance—stand out as the chief, but every group of marine Algæ was elucidated by the researches of Thuret and his colleague. There are few scientific authors whose work has so completely stood the

test of subsequent investigation and criticism. Thuret's style in expounding his results was singularly clear and concise; he was a man of wide education, and possessed the power of expressing his ideas with literary skill. Unfortunately, much of his best work remained unpublished during his life. A portion of the material accumulated by himself and his colleague was embodied in two magnificent works published after his death—the *Notes Algologiques* (1876–80), and the still finer *Études Phycologiques* (1878). These volumes, as well as earlier memoirs, are illustrated by drawings of unequalled accuracy and beauty from the hand of the artist Riocreux, whom Thuret employed. In 1857 Thuret removed to Antibes on the Mediterranean coast, where, on a once barren promontory, he established a botanic garden which became famous throughout the scientific world. Since his death the Antibes establishment has been placed at the disposal of botanical workers as an institute for research. Thuret died suddenly, while on a visit to Nice, on 10th May 1875, when he had scarcely completed his fifty-eighth year. He was a man of considerable wealth, who devoted his money as freely as his time and labour to the advancement of science, but his high reputation rests on the brilliancy of his personal investigations.

The best and fullest account of Thuret's career is that by his friend and fellow-worker Bornet, published in the *Annales des Sciences Naturelles* for 1876. An English notice of his life, by Professor W. G. Farlow, will be found in the *Journal of Botany* for the same year. (D. H. S.)

Thurgau, one of the Swiss cantons. Its area is 387·8 square miles. Of this 327 square miles are reckoned as "productive," 70 square miles being covered with forests, and 7 square miles with vineyards, the remaining 250 being arable or meadow land. Of the 60·8 square miles classed as "unproductive," 59·7 square miles are occupied by the Lake of Constance. The population was 104,678 in 1888, while in 1900 it was 113,221, or 346 inhabitants to the square mile. The population is almost exclusively German-speaking, as in 1888 there were but 271 Italian-speaking, 195 French-speaking, and 61 Romonsch-speaking inhabitants. The existing cantonal constitution is that of 1869. The canton is divided into 8 administrative districts. The capital is Frauenfeld. In 1897 the state revenue of Thurgau was 1,874,140 francs (a rise of 43 per cent. since 1885), and the state expenditure 1,852,891 francs (a rise of 37¼ per cent. since 1885), but in 1898 there was a deficit of 107,260 francs. The public debt in 1897 was 2,710,000 francs.

Thurles, an inland town and urban sanitary district in the county of Tipperary, Ireland, on the river Suir, 87 miles south-west of Dublin by rail. There is an important monthly horse fair, largely attended by English and Continental buyers. Population (1891), 4511; (1901), 4411.

Thurman, Allen Granbery (1813–1895), American jurist and statesman, was born at Lynchburg, Va., on the 13th of November 1813. He early attained distinction at the Ohio bar, and was elected to the supreme bench of the state (1851). Save his one term in this position, and a term in Congress (1845–47), he avoided public office, though prominent in the Democratic party, till 1869, when he was sent to the United States Senate, serving there till 1881. He was recognized as a Democratic leader in the Senate, and served as chairman of the judiciary committee, and as a member of the Electoral Commission of 1877. A law through which the Government secured important advantage in its relations with the bond-aided Pacific railways was due largely to him, and was commonly known as the Thurman Act. In the Democratic conventions from 1876 onwards he was a candidate for the Presidential nomination. In 1888 he was named for Vice-President on the ticket with Cleveland, but was defeated in the election. He died at Columbus, Ohio, 12th December 1895.

Thyrostraca.—As shown by Burmeister in his historical review (1834), these animals, comprised by Linnæus in the genus *Lepas*, first received a more comprehensive title from Cuvier, who called them Cirrhopoda, a word strictly meaning tawny-footed. Lamarck in 1809 altered this into the hybrid form Cirrhipoda, meaning curl-footed, which was subsequently improved into Cirripedia or Cirrhipedia. So long as the group was held to be a subordinate member of the Entomostraca, this term, though not the earliest, was generally accepted. The name Thyrostraca, meaning door-shells or valve-shells, is now to be preferred, as agreeing in termination with the titles of the other two divisions, the Malacostraca and Entomostraca, from which, in the article CRUSTACEA, the present group has been already distinguished. It may conveniently be arranged in two principal sections—the Genuina with cirrhiform feet, and the Anomala without them.

Thyrostraca genuina.—It is with these that Darwin's classical and still essential treatises (*Ray Soc.* and *Palæont. Soc.*, 1851–1854) are almost exclusively concerned. Therein an order Thoracica comprehends the pedunculate Lepadidæ, together with the operculate and sessile Balanidæ and Verrucidæ; a single species without cirrhi constitutes the order Apoda, and a single species with only three pairs of cirrhi the order Abdominalia. Within the last *Kochlorine* (Noll, 1872) with two species, and *Lithoglyptes* (Aurivillius, 1892) with three species, have since been included. But H. J. Hansen (*Die Cirripedien der Plankton-Expedition*, 1899) states that *Cryptophialus minutus*, for which the order Abdominalia was founded, has, like *Alcippe* and other Genuina, its cirrhi on the thorax, not, as Darwin wrongly supposed, on the abdomen. In place, therefore, of the Abdominalia, it will be right to accept the family Cryptophialidæ, v. Martens, side by side with the Lithoglyptidæ of Aurivillius and the Alcippidæ of Gerstaecker. These, with Darwin's three families above mentioned, will complete the section of genuine cirripedes now existent. Gruvel has recently submitted to the Linnæan Society a rearrangement of the Lepadidæ, unfortunately using for the first of his new families the preoccupied name Anaspidæ. It is confusing, but not uninstructive, to find that within the Balanid group such generic titles as *Stephanolepas* and *Platylepas* have been coined. The vernacular name barnacle, traceable to the fable of pedunculate cirripedes hatching out into bernicle geese, has also been transferred to the sessile cirripedes, which are popularly known as acorn barnacles. The scientific student may be congratulated on the fact that a complete and luminous list of all the recent species of Thyrostraca in both sections, down to the year 1897, has been published by Weltner (*Arch. Naturg.*, Jahr. § 63, part i., pp. 227–280, 1898). For fossil species, Woodward's *Catalogue of Brit. Foss. Crust.*, pp. 137–144, 1877, should be consulted. Hoek (*Challenger Reports*, vol. viii., "Cirripedia," pp. 8–11, 1883) gives a brief geological summary down to 1882. In that year J. M. Clarke (*Amer. Journ. Sci. and Arts*, ser. iii., vol. xxiv. p. 55) added a new species to *Plumulites* (Barrande, 1872), remarking that the species in question, *P. devonicus*, "is interesting in being the first representative of fossil barnacles from the Devonian, Barrande's species of *Plumulites* and *Anatifopsis*, as well as the *Turrilepis* of Woodward, being from the Upper and Lower Silurian, and *Plumulites Jamesi* (Hall and Whitf., *Pal. Ohio*, vol. ii.) from the Hudson River group." Since *Plumulites* appears to be a synonym of *Turrilepas* (not *Turrilepis*), the species *Turrilepas Wrightii*, Woodward, 1865, from the Upper Silurian of Dudley, did not long enjoy its isolated eminence as the oldest known cirripede. As pointed out by Dr Bather (*Geol. Mag.*, decade 4, vol. viii. p. 521, 1901), palæontologists themselves have in this branch not very closely followed the progress of their own science, since Dr Ruedemann, in regard to his new *Pollicipes siluricus*, 1901, speaks of "the enormous gap existing between the appearance of this Lower Siluric type and the next Upper Triassic (Rhætic) representatives of the genera *Pollicipes* and *Scalpellum*." Many species of *Scalpellum* from the Wenlock shale of Gotland were described in 1892 by C. W. S. Aurivillius, who at the same time founded the species *Pollicipes signatus* on an almost perfect specimen from the Lower Ludlow of Wisby in Sweden. "Aurivillius

considered that *Pollicipes signatus* showed a closer approach to the Balanidæ than any other of the Lepadidæ, but he, too, in ignorance of the Devonian *Protobalanus* (Whitf.), discoursed needlessly about the gap in the distribution." Dr Bather justifiably anticipates further discoveries, but if, already in Silurian as in modern times, the members of these families had to pass through nauplius and cypris stages to maturity, there is one "enormous gap" between them and the common ancestor of the crustacean class that will not be very easily filled. To later phylogenetic links an addition is offered by Dr Woodward (*Geol. Mag.*, p. 145, 1901), who transfers his *Pyrgoma cretaceum*, 1865, to a new genus *Brachylepas* (Fig. 1), and a new family *Brachylepadidæ*, intermediate between the Rhætic *Pollicipes* and the modern *Balanus*. Among other fossil genera of recent institution, *Archæolepas*, *Lepidocoleus*, *Squama*, *Stramentum*, can only be mentioned as incentives to research. Among living forms, added since Weltner's catalogue, may be noticed *Koleolepas Willeyi*, from the Loyalty Islands (Stebbing, in Willey's *Zool. Results*, part v., p. 677, 1900). This was found in a Turbo shell, occupied also by a Pagurid, and coated with Actinians. The cirripede, which has an elastic peduncle, a crested capitulum, but no valves, and the first cirrhi longer than the rest, should stand near *Eremolepas*, the name given by Weltner in place of the preoccupied *Gymnolepas* (Aurivillius). In the genus *Scalpellum*, *S. giganteum*, Gruvel (*Trans. Linn. Soc.*, 1901) disputes with *S. Stearnsii* (Fig. 2), Pilsbry, 1890, which shall be accounted the greatest. The latter is threatened with a new generic name (Chun, *Aus den Tiefen des Weltmeeres*, p. 502, 1900).

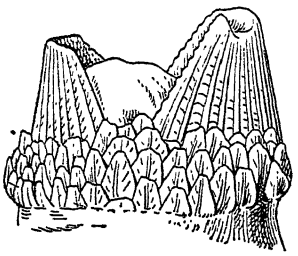

FIG. 1.—*Brachylepas cretacea* (Woodward), from Margate chalk.

FIG. 2.—*Scalpellum Stearnsii*. Two-thirds nat. size.

The horizontal distribution of barnacles over all seas is fully explained by Darwin. The bathymetric range of sessile as well as pedunculate forms down to such depths as twelve or eighteen thousand feet — *Verruca quadrangularis*, Hoek, 1900 fathoms; *Scalpellum regium*, Wyville Thomson, 2850 fathoms—is a more recent discovery. Gruvel (*Contribution à l'étude des Cirrhipèdes*, 1894) found that species frequenting the sea surface or shallow water, notwithstanding their feeble powers of vision, cannot live long when entirely debarred from light. It must therefore be supposed that abyssal forms have gradually acquired such tolerance of darkness as makes their health independent of the sun. Among other singularities of habitat, not the least curious is the freedom with which some small species, especially in the genus *Dichelaspis*, occupy the very jaws of large crustaceans. It is generally stated that cirripedes are confined to salt water, and, generally speaking, that is true. But *Platylepas bissexlobata* (De Blainville), from the west coast of Africa, is sometimes found entirely buried, except its operculum, in the skin of the manatee. Now, since it seems this *Manatus senegalensis* "freely ascends the rivers, frequents the lagoons, and has even been captured in Lake Tchad," we may infer that its parasite travels with it. Whether the journey is in any way detrimental to the cirripede, those should determine whom opportunity favours. Studer (*Crustacea of the Gazelle*, 1882) records *Balanus amphitrite*, Darwin?, from roots and stems of mangroves in the Congo, where, he says, "it follows the mangroves as far as their vegetation extends along the stream, to six sea-miles from the mouth." Darwin notes *B. improvisus* as quite tolerant of water not saline. Why the Thyrostraca, so hardy, so widely dispersed and multitudinous, and with a history so prolonged, should not have made more extended and more independent incursions into fresh water remains a problem. Though the *Ornitholepas australis*, Targioni Tozzetti, 1872, found on the tail feathers of a bird, represents only the cypris-larva of a cirripede, it still shows one of the many facilities for dispersion which these creatures enjoy. A striking instance of their abundance is cited by Aurivillius (1894) from a report by Captain G. C. Eckman, who late in the summer observed great masses of *Lepas fascicularis* forming broad belts in the North Sea. Aurivillius himself examined a humpback whale which had as many as fifty specimens of *Coronula diadema* on each side of its head. He believes that the cetacean approaches not only rocks but ships in the hope of freeing itself from its lodgers. Yet the fact that the long, soft *Conchoderma auritum* stands exposed on the *Coronula*, sometimes ten on one, indicates that the whale can have little chance of evicting its tenants, even at the expense of rubbing off the eighteen flattened horns of its own skin embedded in cavities round the domed base of the Coronula shell. The fecundity in the genus *Lepas* has struck many observers. Hoek (*Chall. Rep.*, vol. x., "Cirripedia," 1884) notes that, while in *Scalpellum* the number of eggs may be less than a hundred, "in *Lepas anatifera* it amounts, on the contrary, to many thousands and tens of thousands." In the same treatise Dr Hoek has useful chapters on the anatomy, development, and sexes of the group, with references to the important researches since Darwin by Krohn, Claus, Kossmann, and others. Francis Darwin, in the life of his father (vol. iii. p. 2, 1888), says, "Krohn stated that the structures described by my father as ovaries were in reality salivary glands, also that the oviduct runs down to the orifice described in the *Monograph of the Cirripedia* as the auditory *meatus*." Hoek, however, observes that the interpretation of the glands as salivary is not given by Krohn as his own opinion, but only quoted from Cuvier. Hoek himself proposes to call them pancreatic glands.

On the absorbing question of development, T. T. Groom (*Phil. Trans.*, vol. clxxxv., 1894) supplies a full bibliography, beginning with the pioneers Slabber, 1778 (properly 1769), and J. Vaughan Thompson, 1830. Groom's monograph was almost immediately supplemented by Chun's chapters on the same subject (*Bibliotheca Zoologica*, Heft 19, Lieferung 2, 1895), to which an important discussion is contributed by H. J. Hansen (*Cirripedien der Plankton-Exp.*, 1899). He insists on the value of the upper lip or labrum for generic distinction, and as an aid in affiliating larval forms of different stages to their several species. He cites Groom's evidence that larvæ obtained from the egg readily go through one moult in the aquarium, and the known fact that the last larval stage is marked by a longitudinal series of six pairs of immovable spines or processes. He considers, then, that by a judicious comparison of larval forms with these two easily determinable stages the poverty of existing information on the subject may be gradually, if laboriously, diminished. The large and peculiar *Archizoea gigas* of Dohrn must, he thinks, belong to the Lepadidæ as a larva in the last stage, but not, as v. Willemoes Suhm supposed, to *Lepas australis*, or even to the genus *Lepas* at all.

Thyrostraca anomala.—This section comprises Darwin's Apoda, the footless, Lilljeborg's Suctoria, called by Fritz Müller the Rhizocephala, or rootlet-headed, and the group to which Lacaze-Duthiers gave the alternative names Ascothoracida, sac-bodied, or Rhizothoracida, rootlet-bodied. For the present these names may be dispensed with in favour of their equivalents, the three families Proteolepadidæ, Sacculinidæ, and Lauridæ. The first is still limited to the single genus and species *Proteolepas vivincta*, Darwin, parasitic within the sac of another cirripede. Nothing is certainly known of its development, except that the ova are extremely small, but H. J. Hansen (*Die Cirripedien der Plankton-Exp.*, p. 53, 1899) argues that various nauplii of a type not previously described may probably be referred to this group or family, to which man's ignorance rather than nature's insufficiency has hitherto given so trifling an extension. The second family, discussed by Delage, Giard, Kossmann, and others, has no dearth of genera and species, though about several of them the information is scanty enough. Almost all of them are parasitic on other crustaceans. *Sphærothylacus polycarpus*, Sluiter, 1884, has an ascidian for its host. *Sarcotaces* (Olsson, 1872) has two species parasitic in fishes. But these exceptional and dubious forms do not obtain nutriment by sending rootlets in a rhizocephalous manner into their patrons. The family Peltogastridæ is sometimes separated from the Sacculinidæ, and sometimes made to do duty for both, the latter course being improper, since *Sacculina* (J. Vaughan Thompson, 1836) is not, as has been supposed, preoccupied, and must therefore take precedence of *Peltogaster* (Rathke, 1843). In the same family stands the genus *Sylon*, noted by Kröyer without a name in 1842, named by him without a description in 1855, described by Michael Sars in 1869, and published by G. O. Sars in 1870. Hoek (*Challenger Rep.*, vol. xxiv. App. A, 1888) will orientate the English reader on this genus. For the complicated parasitism of isopods and Sacculinidæ on the same hosts Giard and Bonnier (*Bopyriens*, p. 197, 1887) should be consulted.

The remaining family may till further knowledge be allowed to cover four remarkable species, three of them resident on Anthozoa, one on an echinoderm. Only the first, the celebrated *Laura gerardiæ*, Lacaze-Duthiers, 1865, sends such rootlets into its host as would justify the term Rhizothoracida. The small sinuous segmented body is enclosed, except for one small opening, in an enormous sac-like carapace, between the lamellæ of which are protruded from the body the ovary and "liver," both large, bifurcate, and ramified. It is this sac-like and not valvular carapace, therefore, that justifies the term Ascothoracida. But *Synagoga mira*, Norman, 1888 (*Brit. Assoc. Report* for 1887,

has the body covered by two nearly circular valves instead of a sac. *Petrarca bathyactidis*, G. H. Fowler (*Quart. Journ. Micros. Sci.*, vol. xxx. part ii. p. 115, 1889), has a bilobed carapace, ventrally open. *Dendrogaster astericola*, Knipovitch (*Biologisches Centralblatt*, vol. x. p. 707, 1891), is a multilobular sac, with apparently indistinct segmentation of the body proper on the dorsal side. For this highly problematic group the original authorities should by all means be consulted. The student may then be asked to compare the account of *Synagoga mira* both with the figure of the cypris-stage of *Dendrogaster astericola* and with the figure of the "indeterminate animal found on Gerardia," about which Lacaze-Duthiers asks, "Is it the cypris-stage of Laura?" (*Mém. Acad. Sci.*, vol. xlii. p. 160. pl. 1, fig. 102, 1883). *S. mira* was found, like *Laura gerardiæ* (Fig. 3) in the Mediterranean, and found like it attached to an antipatharian. Its six pairs of limbs are not like the bare and simple feet of the *Laura*, but two-branched and setose as in the ordinary cypris-stage of the cirripede. The conclusion, therefore, from these facts and from the suggested comparisons, seems at least extremely probable that the question

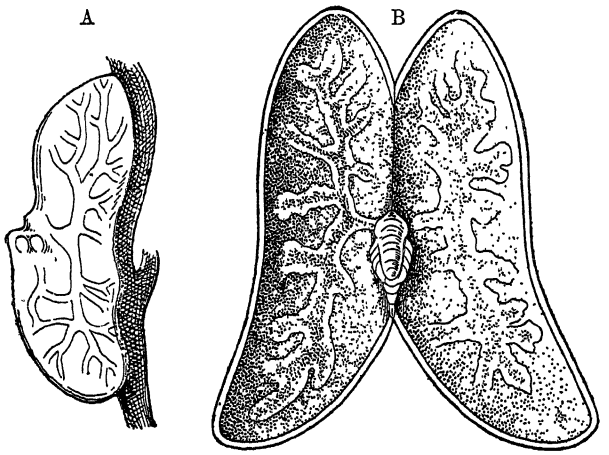

FIG. 3.—A, *Laura Gerardiæ*; B, carapace slit open to show the body proper.

asked by Lacaze-Duthiers should be answered in the affirmative, and that *S. mira* is either the cypris-stage of *Laura gerardiæ* or of some congeneric species. In Lacaze-Duthiers's highly-elaborated memoir it should be noticed that he uses the term "cirrhes" rather misleadingly, not for cirrhiform feet, but as the equivalent of setæ. Also he gives two different reckonings of the segmentation, counting first eleven body segments without the caudal furca (p. 40), and then the caudal furca as itself the eleventh segment (p. 41). Of *Petrarca* the development is not yet known. The points of agreement and difference between it and *Laura* are carefully drawn out in the essay by Dr Fowler, who inclines to favour a close relationship between the Thyrostraca and Ostracoda. To the extreme development of the carapace in *Laura* as compared with the segmented body it would be difficult to find among crustaceans any analogy more striking than that of the great ovarial expansions in *Nicothoe astaci*, the little copepod parasite of the common lobster. The compactness of the class Crustacea is generally admitted; of the precise affinities of its subdivisions there is still much to learn. (T. R. R. S.)

Tiber (Italian, *Tevere*), a river of Italy. It traverses the Tuscan Apennines—in which it rises at a point some 5 miles north of Pieve San Stefano—in a series of picturesque ravines, skirts the west foot of the Sabine Mountains in a broad, shallow valley, then crosses the Roman Campagna, cutting its way through Rome, and finally enters the Tyrrhenian (Mediterranean) Sea by two arms at Ostia and Fiumicino. Its principal tributaries are the Paglia, the Nera, and the Anio or Teverone, and it is generally navigable by boats up to the confluence of the Nera, a distance of 104 miles. The total length of the river is 240 miles, of which 21 miles lie between Rome and the sea. This latter portion of the river's course, although the depth varies from only 7 to 20 feet, and in places at low water does not exceed 4 feet, is nevertheless navigated by vessels up to 180 tons burden. The area of the river basin is 6845 square miles. The stream is heavily charged with sedimentary matter, and from that circumstance got its ancient epithet of *flavus* (tawny). It does not, however, form a delta proportionate to the volume of its water. This is owing to the existence of a strong sea current flowing northwards close to the shore, to the sudden sinking of the sea to a great depth immediately off the mouth of the river, and possibly also to the permanent subsidence of the Italian coast from the Tiber mouth southwards to Terracina. Still it has in the course of centuries formed a small delta between its two arms, the district known to the ancients as the Isola Sacra (Sacred Island), about 3 miles across. From Rome to the sea the fall is only 6·5 : 1000. Fiumicino is connected with the river by a canal, dug by Trajan, 2½ miles long, 80 to 130 feet wide, and with a minimum depth of 5 feet. The lower course of the Tiber has from the earliest ages been subject to frequent and severe inundations, those of 1598, 1870, and 1900 having been especially destructive; but since the year 1876 the municipality of Rome, assisted by the Italian Government, has taken steps to check, and possibly to prevent, the occurrence of these calamities, by constructing embankments of stone, resting on caissons, for a total distance (counting in both sides of the river) of 6 miles, at a cost amounting in 1900 to a total of £5,000,000. The portion of the river thus embanked, and otherwise improved by straightening and clearing the channel near the Tiber island, is that which stretches from the new Ponte Margherita (near the Piazza del Popolo), at which point the river is 80 yards wide, to the Ponte Palatino, below the Tiber island, where its width increases to 113 yards and its depth is 16 to 43 feet. In December 1900 fully a quarter of a mile of the solid masonry of this new embankment (made in 1885–86), on the right bank, between the Garibaldi and the Cestio bridges in Rome, collapsed and was swept away by the stream, while weakness and partial subsidence manifested themselves at other points of the embankment within the city. (J. T. Be.)

Tiberias, now *Tabarieh*, on the western shore of the Sea of Galilee. It is the seat of a mission of the United Free Church of Scotland with hospital and school, of a Franciscan hospice, church, and school, and of a Greek monastery and school. On a spur to the south of the town are the ruins of a fortress probably built by Herod. The population of 4000 includes about 2600 Jews.

Tibet.—The main outlines of Tibetan physiography have been so well illustrated already in the article on TIBET in vol. xxiii. (ninth edition) of this Encyclopædia, as to leave little more to be said, in spite of the continuous activity in geographical research which has been maintained in these regions during later years. The Indian approaches to Tibet have been systematically closed against travellers by the jealous interference of Tibetan and Chinese officials, so that nearly all the fresh geographical information which has been added since 1885, or thereabouts, to our previous knowledge of the country, has been obtained by travellers who crossed the border either from Kashmir on the west or from Turkestan and China on the north and east. Although Lhasa is within 200 miles of the frontiers of Sikkim, no European has lately succeeded in reaching that mysterious city, and our knowledge of it is still chiefly derived from native explorers. On the northern borders of the great Changtang—the central lake region which is flanked to the south and west by the Himalaya and their northern offshoots, and to the east by a vast mountain wilderness which contains the sources of the great rivers of Burma and China—the Kuen-lun and the secondary mountain chains diverging therefrom have been scientifically explored by a series of travellers following on the footsteps of Prjevalsky; and it is here that we have

to note certain amendments which have become necessary to our previous conceptions of Tibetan mountain configuration. The surveys of the Pamir Boundary Commission in 1895, followed by those of Captain Deasy, subsequently show that it is no longer correct to describe the Tibetan plateau as merging into the Pamirs on the west. No part of the Pamir region directly borders Tibet, nor can there be traced that connexion between the Kuen-lun and the mountains bordering Lake Victoria which was claimed by Stoliczka. The Kuen-lun, indeed, in its extreme north-western offshoots, abuts on what is known as the Mariom Pamir, in the basin of the Zarafshan river, but the Kuen-lun has ceased to represent the northern boundary of Tibet politically (if not geographically) long before it touches the Zarafshan, and the Mariom Pamir (if it can be recognized as a true Pamir) is separated by the whole border of the double range of the Sarikol from the "Great" Pamir of Lake Victoria. A northern offshoot of the giant Muztagh chain, forming an irregular transverse watershed, which connects the eastern and final buttresses of the Muztagh with the Kuen-lun in about 80° E., represents the western boundary of Tibet as recognized politically in the present day, although the Changtang (or tableland) to the west of it differs in no essential physical aspect from the Aksai chain to the east. The long, straight axis of the Kuen-lun, extending through 20 degrees of longitude, along the parallel of 36° N., and defining the northern edge of the great central Tibetan upheaval as clearly as does the main snowy chain of the Himalaya on the south, is now known to be traversed by at least one important river (the Kiria), which passes from the plateau to the plains of Turkestan across the axis in about 82° E., and is finally lost on the sands of the Takhla Makan.

In the eastern section of the Kuen-lun, where the barren wind-swept solitudes of the Tsaidam stretch northwards to the Altyn Tagh and Nan Shan ranges, our geographical knowledge has been greatly extended by Russian explorations and by the researches of Sven Hedin. The absolute elevation of the Tsaidam uplands is about 9000 feet above sea, and its vast spread of desert and swamp is shown to be allied to the Tibetan tableland in configuration and physical aspect, and to be entirely distinct from the Turkestan depression which centres about Lob Nor to the north of it. We may therefore fairly include Tsaidam as an integral part of Tibetan geography. Such was the view taken by General Walker in the article in the ninth edition of this work, in contradistinction to later authorities, notably Mr W. Rockhill, who is disposed to regard Tsaidam politically as a sort of no man's land, because of the ethnographical and administrative distinctions existing between its nomadic and marauding Mongolian and Tibetan inhabitants and the tribes and people of the south.

In eastern Tibet much advance has been made in unravelling the secrets of Asiatic hydrography by the identification of the sources of the Yangtse, the Hoang Ho (Yellow river), the Mekong, and the Salween, all of which originate in the mountain borderland of eastern Tibet, and can now be placed with some approach to accuracy in their relative geographical positions on the map of Asia. The climate and conformation of the surface of the central tableland have also been the subject of scientific observation by the many distinguished travellers who have crossed it, and much new light has been thrown on the ethnographical conditions of its nomad inhabitants.

For these and many other recent additions to our scientific knowledge of Tibet we are indebted to a number of travellers, Russian, English, French, American, Swedish, and Indian, a brief summary of whose work is necessary in order to illustrate the gradual progress of scientific investigation.

Russian explorers.

The great Russian explorer Prjevalsky, although he was not, strictly speaking, an explorer of Tibet, did very much incidentally towards determining the conformation of its north-eastern and eastern mountain systems. His third journey into Central Asian wilds, which lasted from March 1879 to October 1880, included the sources of the Hoang Ho, or Yellow river, till then unmapped and unknown. His fourth journey, between November 1883 and October 1885, covered much of northern Tibet, and established the true character of Tsaidam. It was when setting out in 1888 to make an attempt to reach Lhasa that he died.

After Prjevalsky's death, Roborovski, with several companions, explored the western ranges of the Kuen-lun, and crossed southwards into Tibet, tracing the course of the Kiria river to the north-western plains of the central plateau. The distinguishing feature of these explorations, led by Russian officers, is their high scientific value, and the contributions they have offered to the botany, natural history, geology, and meteorology of the regions under investigation in addition to the actual geographical data attained. The Kuen-lun is known in their writings as the Russian Range.

Indian native explorers.

Following the example of previous distinguished native explorers of the Indian Survey, Lama Ugyen gyatso, who worked in direct connexion with Sarat Chandra Das of the Bengal Educational Department from 1878 to 1883, made Lhasa his chief objective. He was originally a teacher of Tibetan in a Darjiling school, and being deputed to take tribute from his monastery to Tashilunpo and Shaia, he secured permission from the Tibetan authorities for Chandra Das to visit the Tashilunpo monastery, where his name was entered as a student. This was the opportunity for a series of most valuable exploratory journeys through the Tibetan provinces adjoining the Indian and Nepalese frontiers, which have added greatly to our stock of information about Lhasa and the districts surrounding that city. In their first journey the travellers set out from Jongu in Sikkim, and traversing the north-east corner of Nepal, crossed into Tibet by the Chatang la, and travelled northwards to Shigatsé and Tashilunpo. They returned by much the same way to near Khamba djong, and re-entered Sikkim by the Donkhya la. The journey was fruitful of information and valuable for mapping.

After a second journey into southern Tibet, the lama undertook another journey in 1883 to complete and extend his former surveys. Travelling by way of Khamba djong directly to Gyantsé and Shigatsé, he turned eastwards at the latter town, finished the survey of the Yamdok tso, and crossed the Himalaya into the valley of the Lobratsangpo or upper Manas river. At Shakhang djong he was arrested, and his true character discovered. He managed, nevertheless, to extricate himself, and turning north-eastwards he passed through Chetang, and reached Lhasa by way of Samyé monastery. From this city he started for Darjiling, which he reached on 15th December 1883.

Sarat Chandra Das's reports of his two journeys were published by the Indian Government, but for political reasons were until about 1889 kept strictly confidential. In 1899 they were edited, but not yet published, by the Royal Geographical Society. They contain a great amount of valuable information on the geography, ethnology, and religion of Tibet. Chandra Das also brought back from his journeys a large number of interesting books in Tibetan and Sanskrit, the most valuable of which have been edited and published by him, some with the assistance of Ugyen gyatso. As a reward for these geographical and other services Chandra Das was made C.I.E. and granted a *jaghir*.

W. W. Rockhill, 1888–89, 1891–92.

In 1882 Mr Rockhill, an American, leaving the lamasery of Kumbum in north-western Kansu with three Chinese servants and a small caravan, proceeded round the north shore of Koko Nor, crossed eastern Tsaidam, and explored some of the rivers and lakes directly south of that region. Leaving Barong Tsaidam, he travelled south by way of the sources of the Yellow river, till he reached the Dré chu (upper Yangtse-kiang), which he crossed to the north of the important trading centre of Gyékundo. From this point he followed the valley of the Dré chu till about lat. 30° 30′, when he passed into the basin of the Yalung river, traversed the Horba states, and finally reached Tachienlu by the Gi la and the valley of the Darchu.

In 1891 Mr Rockhill, starting again from Kumbum with three Chinese, passed south of Koko Nor through the country of the pastoral Panaka Tibetans, and by a very difficult pass (Wahon la) entered again the basin of the Tsaidam. He then turned west, followed the base of the south Tsaidam range as far as the Naichi Gol, where he entered the southern mountainous region forming the northern borderland of Tibet. From this point the traveller followed a general south-westerly direction around the heads of all the feeders of the upper Dré chu, and thence into the lake region of northern central Tibet, crossing Bonvalot's route south of the Chib-chang tso and that of Bower a few days farther south. Near the Namru tso his farther progress south was arrested, and he was compelled to

take an easterly course. After making a long détour north, often crossing the roads previously travelled by Bonvalot and Bower, and passing by Riwoche, he came to Chamdo and Tachienlu. The results of Mr Rockhill's two journeys were most valuable.

Gabriel Bonvalot, 1889-90. Bonvalot, acompanied by Father Dedeken of the Belgian Catholic Mission and Prince Henri d'Orléans, left Charkalik, south-west of the Lob Nor in November 1889, and taking a very nearly due southerly course, reached on the 13th of February 1890 the eastern end of the Tengri Nor. Then pushing on southwards, he crossed the Nyinchen tang la and entered the Dam district near the Lhasa–Hsining high-road. Here the party was stopped by Tibetan authorities and forced to take the tea route through Chinese Tibet (Gyade) by way of Batasumdo, Chebotenchin, Riwoche, Chamdo to Chiangka, near the upper Yangtse-kiang, whence they proceeded to Tachienlu by Batang and Litang. Bonvalot noted some extinct volcanoes in the northern Tibet desert.

Captain H. Bower, 1891-92. Accompanied by Dr W. G. Thorold, of the India Medical Service, and a native sub-surveyor, Captain Hamilton Bower, I.S.C., set out from Leh on 1st June 1891, and crossed the Lanak la and the Ladak frontier on 3rd July. From this point the party took a general easterly direction past the Mangtza tso, Horpa tso, Charol tso, and around the northern end of the Aru tso, all important lakes, at an average altitude of about 16,500 feet. From the Aru tso the travellers took a south-easterly direction across the great northern plateau or Changtang till they reached the south-east side of the Garing tso, in about 31° 30′ N. and 89° 10′ E. At this point Bower was stopped by some of the headmen of the Tibetan pastoral tribes (here under the rule of Lhasa), and obliged to make a long circuit to the north well out of Lhasa territory, and then eastward—till he struck the road to Chamdo through Gyade or Chinese Tibet. Crossing the Hsining–Lhasa road a little south of the Dang la range, and about two days' journey north of Nagchuka, Captain Bower crossed the Su chu, and following a course parallel to the Gyama-nu chu, he made his way to Riwoche and thence to Chamdo, from which town he followed the Lhasa–Tachienlu high-road to the latter town, which he reached on 10th February 1892. The results of Captain Bower's journey were all of first-class importance.

Miss A. R. Taylor, 1892. Miss Annie R. Taylor, an Englishwoman of the China Inland Mission, started from Tao-chou (Kansu) in September 1892, accompanied only by five Asiatics. Passing by the famous lamasery of Labrang, south of the Yellow river, she crossed that river and traversed the southern part of the country inhabited by the predatory Tibetan tribes called Golok. Thence, after crossing the upper Za (or Tsa) chu, which flows by the town of Kanzé, she pursued her journey to the upper course of the Yangtse-kiang (Dré chu), crossing that river somewhere near where A. K. had crossed it in 1881 and Rockhill in 1889, and then came to the town of Gyékundo. From this point she seems to have followed the Chamdo road to near that town, when she turned westwards and continued in that direction till she came on the highroad from Lhasa to Hsining Fu somewhere north of Nagchuka. Here, like all other European travellers who have tried to reach Lhasa from the north, she was stopped by the Lhasan authorities. She appears to have followed about the same route on her way back to China, for she again went to Gyékundo and thence by the highroad, followed previously by A. K. and Rockhill, to Tachienlu in Szechuen, where she arrived 12th April 1893.

Dutreuil de Rhins and F. Grenard, 1893-94. In 1893 Mr J. L. Dutreuil de Rhins and F. Grenard, both Frenchmen, left Cherchen, with Lhasa as their objective. After crossing the Kara muren davan in the Arka Tagh, they entered the lake region of north Tibet and followed a general southerly direction across low ranges of hills and by numerous small lakes till they arrived in 32° 30′ N., where they changed direction to east-south-east, passing to the north of the Chargut and Gyaring lakes. The travellers were able to push on as far as the north-eastern bank of the great Tengri Nor, which they reached 30th November 1893. Here they were finally stopped by the Tibetans, and after a delay of six weeks passed in vain attempts to obtain permission to go to Lhasa, they were only allowed to proceed to Nagchuka on the Hsining–Lhasa road, and to continue by the Gyade route to Gyékundo, near the upper Dré chu, and thence to Hsining in Kansu. From Nagchuka the travellers followed a heretofore unexplored road through the Gyade country, crossing Rockhill's route in the Peré-Sangyi districts near Trashiling (their Tachi gomba). The road followed by them to Gyékundo is called by Tibetans the upper road (*gong lam*), and had apparently been followed previously by Miss Taylor. Reaching Gyékundo (or Giergundo) on 21st May 1894, the travellers started for the Koko Nor and Hsining on 1st June; but the party was attacked near Tungbumdo (Tumbumdo of previous travellers), and Dutreuil de Rhins was killed on 5th June. Mr Grenard after a few days resumed his march, passed east of the Noring tso, the eastern extremity of Tosu Nor, and thence by the south-east corner of Koko Nor to the town of Hsining Fu in Kansu. The results of this exploration have been a large number of maps and a report of great scientific importance.

St George R. Littledale, 1895. Mr Littledale, an Englishman, accompanied by his wife, left Khotan in the early part of 1895, and travelling thence to Cherchen, he turned southwards, and following up the course of the Cherchen daria to a point near its source, he continued in that direction between 87° and 89° E. across the northern plateau of Tibet till he reached the Zillang (or Garing) tso. Pursuing, amidst great difficulties, his southerly course, he finally reached the western bank of Tengri Nor. Pushing rapidly on in the direction of Lhasa, when not over 50 miles away from the city (camp, 30° 12′ 12″ N.), he was finally stopped by the Lhasan authorities and obliged, in great part on account of the severe illness of Mrs Littledale, to give up the attempt to reach Sikkim, and to take a direct trail to Ladak. In the latter part of this remarkable journey Littledale's route lay parallel but to the south of the routes followed previously by Nain Sing, and more recently by Bower. Passing by Rudok, the party re-entered Ladak at the village of Shushal on 27th October 1895, and Leh on 2nd November. Mr Littledale surveyed about 1700 miles of country between Cherchen and Shushal, and brought back a valuable collection of plants, which, added to those collected by other travellers in this part of Tibet, has enabled botanists considerably to extend their very scanty knowledge of this region.

Captain M. S. Wellby, 1896. Accompanied by Lieutenant Malcolm of the 93rd Highlanders, Captain Wellby, of the British army, left Leh on 4th May 1896. The travellers were compelled to enter Tibet by way of the Lingten tso in 35° N. From this point they turned due east, and continued, with the usual incidents experienced by all travellers in these regions—cold, storms, lack of food and of grass, loss of ponies and pack animals, &c.—until they reached the northern branch of the Dré chu, the Chumar. Passing into the valley of the Nomoron Gol, south of the Tsaidam, they made their way by Barong Tsaidam to Tankar and Hsining Fu by the highroad along the northern shore of the Koko Nor.

Captain H. H. P. Deasy, 1896. Captain Deasy, of the British army, left Leh on 27th May 1896, and crossing the Lanak la, passed by the Mangtza tso, north of the Horpa tso, to Yeshil kul. Thence he endeavoured to proceed due east, but was obliged by the nature of the country to turn south, crossing Bower's route on the west side of the Aru tso. He finally completed a valuable survey of an important part of western Tibet.

Sven Hedin, 1896. In 1896 Sven Hedin, a Scandinavian, left Kopa, a point about 100 miles south of Cherchen, and after crossing the Arka Tagh took an easterly course between that range and the western continuation of the Kokoshili range till he entered the valley of the most northerly feeders of the Dré chu, when he passed into the valley of the Naichi Gol and entered the Tsaidam. His careful observations concerning the meteorology of this region are of great value, and his surveys between Kopa and the Naichi Gol were in a country not previously explored. The country traversed, however, can hardly be considered as forming a part of Tibet, though its configuration is the same as that farther south in the great Tibetan plateau crossed by other travellers.

Sven Hedin, 1901. During his second journey in Central Asia, Sven Hedin left Charkalik in May 1901, intending to cross Tibet in a diagonal direction to the sources of the Indus. Arriving within fourteen days of Lhasa, he left the bulk of his caravan and pushed rapidly on towards that city, but was stopped when about five days from it. Rejoining his caravan, he turned westwards, and passing through the country previously traversed by Bower and Littledale, he reached Leh on 20th December 1901.

Captain P. K. Kozloff, 1900–1901. In May 1900 Kozloff, in command of the Russian Geographical Society's expedition to Central Asia and Tibet, left Barong Tsaidam, and travelling southwards, came to the Dré chu (his Ndu chu or Blue river), at about the same point as Rockhill in 1889. Assisted by the old chief of Nyamtso, he crossed the river and reached Gyékundo (his Jarku Lomba). One stage beyond this place he left the route followed by former travellers and pushed northwards to near the town of Chamdo, where after a sharp fight with the natives he turned eastwards. The winter was passed in the valley of the Ra chu, a tributary of the Chamdo chu (his Dza chu), and excursions were made as far as Dergé droncher. In the spring of 1901 the expedition resumed its march eastwards around the Dré chu and the Ja chu (Yalung river), followed up the left bank of the latter, and got back to Russian Lelu (Oring tso) on 30th May 1901. The scientific results of this expedition, so far as can be judged from the very meagre accounts published, appear to be important.

Physically Tibet may be divided into two parts, the *lake region* in the west and north-west, and the *river region*, which spreads out on three sides of the former on the east, south, and west. The lake region extends from the Pangong tso in Ladak, near the source of the Indus, to the sources of the Salween, the Mekong, and the Yangtse. This region is called the Changtang (Byang Tang) or "Northern Plateau" by the people of Tibet. It is some 700 miles broad, and covers an area about equal to that of France. From its great distance from the ocean it is extremely arid, and possesses no river outlet. The mountain ranges are spread out, rounded, disconnected, separated by flat valleys relatively of little depth. The country is dotted over with small lakes, many salt or alkaline, and intersected by streams, and the soil is boggy and covered with tussocks of grass, thus resembling the Siberian tundra and the Pamirs. Its average altitude is over 16,000 feet, the northern portion of it being the highest. The southern portion, from Lake Pangong to Tengri Nor, is inhabited by pastoral tribes of Tibetans, and possesses a few hamlets, such as Ombo, Rudok, and Sendja djong. The river region comprises the upper courses of the Brahmaputra (Yara tsangpo), the Salween (? Gyama nyul chu), the Yangtse (Dré chu), the Mekong (Nya-lung chu), and the Yellow river (Ma chu). Amidst the mountains there are many narrow valleys, partially cultivated from an altitude of 12,000 feet downwards, with here and there fine forests covering the mountain sides. Villages of high stone-built houses are to be found wherever the valley bottoms open out enough to afford a little space for agriculture. Barley and turnips are about the only products of the higher valleys; as one reaches lower levels, wheat, buckwheat, cabbages, potatoes, apricots, apples, and peaches are found, and in the so-called "hot country" (*tsa-rong*), in the southern part of Tibet, rice, oranges, pomegranates, and jujubes are raised successfully.

Geography.

The Tibetan race, which probably belongs to the Turko-Mongol stock, is divided between the tent-dwelling Tibetans of the lake region and the transition zone between it and the river region, and the sedentary population of the valleys. The tent-dwelling Tibetans are called by the Tibetans Dupa or Drupa (*hbrog-pa*), or "Steppe dwellers." They probably present the purest type of the race. An exception may be made in the case of the Tibetans of the Koko Nor region, also called Panaka, who show a Mongolized type. The males measure about 5 feet 5 inches; the females not appreciably less. The head is brachycephalic; the hair, when worn, is nearly invariably wavy; the eyes are usually of a clear brown, in some cases even hazel; the cheek-bones are high, but not so high as with the Mongols; the nose is thick, sometimes depressed at the root, in other cases prominent, even aquiline, but usually narrow, though the nostrils are broad. The teeth are strong but irregular; the ears, with tolerably large lobes, stand out from the head, but to a less degree than with the Mongols. The mouth is broad, the lips not very full and, among the people living in the lower altitudes, decidedly thin. The beard is very sparse, and with the exception of the moustache, which is sometimes worn, especially in central Tibet, it is carefully plucked out with tweezers. The shoulders are broad, the arms round; the legs are not well developed, the calf is especially small. The foot is large, the hand coarse. The women are usually stouter than the men, their faces much fuller. The colour of the skin of the Tibetans is a light brown, frequently nearly white, except where exposed to the weather, when it becomes a dark brown, nearly the colour of the American Indian's. Their voices are full, deep, and powerful. They can endure exposure without any apparent inconvenience. Hunger they can also endure; though the nature of the food they use is such that they cannot stand absolute privation for any considerable length of time, they can easily exist for long periods on starvation rations.

People.

The sedentary population of Tibet has to a greater or less degree the same physical traits as the Drupa, but as one approaches China, India, or the border lands generally, one observes that the admixture of foreign blood during many centuries has considerably modified the primitive type. Among the customs of the Tibetans, that which is perhaps the most peculiar is the existence among them of polyandry, the brothers in a family having one wife in common. Polygamy is not unknown in Tibet, especially in the eastern parts of the country. Among the pastoral tribes monogamy seems to be the rule.

The population of Tibet has been estimated by various writers at from 3,000,000 to 8,000,000; the lower estimate seems the more acceptable; and in it should be counted the Tibetans of Ladak, Sikkim, and adjacent districts under British sovereignty. The latest estimate of the population of Tibet is that made by order of the emperor of China in 1737. According to it the grand total of the population for the whole of Tibet in the middle of the 18th century, was about a million and a half. No means exist of checking these figures, but when we take into account the existence of polyandry and promiscuity, the configuration of the soil, the ever-increasing number of the lamas, slavery, the frequent terrible ravages caused by smallpox, &c., it seems highly probable that the present population of the country, except in some highly-favoured districts, does not greatly exceed that given for 1737, at which figure it was estimated by Csoma de Koros, writing somewhere about 1830. If we add the Tibetans of north-western Kansu, the Koko Nor, and adjacent districts not included by Csoma de Koros, who do not, it is believed, number over 250,000, it would certainly appear that the total Tibetan population would hardly reach 3,000,000 as a maximum.

Political divisions.

Tibetans divide their country into five provinces. (1) *Amdo*, which comprises that part of the Chinese province of Kansu which is inhabited by Tibetans, and Koko Nor region, extending southwards to the Yellow river and westwards as far as the Tsaidam. Amdo is inhabited in its eastern part by Tibetans, called Rongwa or "agriculturists," and in the western by pastoral tribes, collectively called Panaka or Panakasum. (2) *Khams* or *Khamdo*, which includes all eastern Tibet between the Chinese provinces of Szechuen and Yunnan, and the district of Lhorong djong, which forms the eastern border of the Lhasa-governed territory. This province is divided into the five Horba tribes, the eighteen Nyarong states in the valley of the upper Nyalung, and the districts of Litang, Batang, Dergé, Gartok, Chamdo, and Draya. In Khamdo, but subject to the direct rule of Lhasa, are several small districts; the principal are Nyarong, Tsarong, and Mär Khams or "Lower Khamdo." Most of these districts are governed by *déba* or chiefs, while a few have kings or *gyalpo*, the most powerful of the latter being the king of Dergé and of Chagla, or, as it is better known, Tachienlu. Khamdo is under the direct rule of the Chinese provincial authorities of Szechuen. Some of its rulers send also tribute missions to Peking. For convenience of classification, we may include in Khamdo a long strip of country extending along the northern border of the Lhasa territory of Lhorong djong and Larego as far as Tengri Nor, and bounded to the north by the Dang-la mountains, which is designated by Tibetans as *Gyade* or "the Chinese province." This strip of country has its own native chiefs, but is under the control of a high Manchu officer stationed at Lhasa, known colloquially as the "Superintendent of Savage Tribes." The third political division of Tibet is *Wu* (written Dbus), meaning "Central." It includes Lhasa, and a large number of outlying districts in south-eastern Tibet, such as Po yul, Pemakoichen, Za yul. The

pastoral or Drupa tribes, north and north-east of Tengri Nor, are also under its rule. Lhasa is colloquially designated as Téba gzung, "the very centre." The fourth and fifth divisions of Tibet, called *Tsang* and *Nari* (Mngah-ris), include, the first, all south-west Tibet as far as Lake Manasarowar; the second, the whole country around the sources and along the upper course of the Indus and the Sutlej, and also all north-western Tibet generally. Tsang and Nari are under the rule of Lhasa, all the high civil and military authorities in these provinces holding their offices from it.[1]

The chief towns of Tibet.

Tibet hardly possesses a town of first-class importance besides Lhasa. The monastic towns of Tashilunpo (Shigatsé) and Gyantsé on the Nyang chu, a southern tributary of the Tsanpo, which joins that river about 150 miles above Lhasa, are perhaps the best-known towns of the southern districts of Tibet. Both of them are commercial centres of some significance.

Shigatsé, which is at the confluence of the Nyang chu with the Tsanpo, also called Digarcha, is a city of about 9000 inhabitants (exclusive of priests), about ¾ of a mile long by ½ a mile broad. About a mile from the north-east corner of the city is situated a monastery called Konkaling, whilst to the south-west is the far-famed Tashilunpo monastery, the residence of one of the great high priests of Tibet, coequal with the Dalai-Lama of Lhasa. Between the Tashilunpo monastery and the city is the Thom or open market, where all the business of the place is daily transacted. A wall about a mile in circumference surrounds the Tashilunpo monastery, within which are numerous temples and houses, four of the larger temples being decorated with gilded spires. A great wealth of jewels and precious metal is said to enrich the numerous idols of Tashilunpo. The monastery maintains 3300 priests. The city is protected by a fort which stands on a low hill to the north-west, and a garrison of 100 Chinese and 400 Tibetan soldiers is quartered here. The municipal government is in the hands of two däpon assisted by resident Djongpons. The soil around Shigatsé is rich and productive, the elevation being between 11,000 and 12,000 feet.

Gyantsé, the mart for Bhutan, to the south-east of Shigatsé, is described by "the Pundit" as being very similar in size to Shigatsé, but the government is in the hands of one dâpon only, and the fort is near the centre of the city, maintaining a force of 50 Chinese and 200 Tibetans only. At Gyantsé wheat, barley oil, radishes, peas, and ghee are said to be cheap, and the town is famous for its manufacture of various kinds of cloth and of small bells, such as are attached to caravan horses.

Janglache, on the Tsanpo (where the trade-route from Ladak crosses from the left to the right bank of the river), is about 80 miles above Shigatsé. Here again we meet with the usual monastery and fort. Janglache is between 13,000 and 14,000 feet above sea-level.

On the Kashmir (or Ladak) frontier the little town of *Rudok* is important. Through Rudok all the trade of Tibet passes to Leh, and at Rudok is maintained the Chinese outpost which has so persistently interfered with all efforts at European exploration of the country. Nevertheless the political resident at Leh has already visited that town, and it may well happen that its bazaar will soon be as much traversed by Europeans as is Leh itself. Rudok is described as a small town picturesquely situated on the side of a hill standing isolated in the plain near the eastern end of Lake Pangong, across which the official boundary between Tibet and Kashmir now runs. The houses are built in tiers, whitewashed, and walled in. At the top of the hill is a large palace and several monasteries painted red. About a mile away from the foot of the hill is another monastery. Rudok is about 13,300 feet above sea-level, the height of Lhasa being 11,600 feet, and the greatest altitude on the route connecting the two, at the Mariom la (the pass which defines the water-parting between the sources of the Brahmaputra and those of the Sutlej), is 15,500 feet. It is a noteworthy fact in respect of the winter climate of Rudok and of all the towns of the Tsanpo basin that, owing to the intense dryness of the air and the light fall of snow, it seems to be bracing and exhilarating rather than severe. The thermometer apparently never sinks very low, and never approaches the minimum record of Puetra (in the same latitude and at half the absolute elevation), according to the observations of native surveyors.

Tachienlu (Darchendo) is on the extreme eastern boundary of Tibet, bordering the province of Szechuen in China. It is the great tea mart for Tibet, and from Tachienlu the two great trade-routes, the Gya lam and the Chang lam, diverge, the former to Ladak and the latter to Kashgar.

In eastern Tibet another well-known trading town is *Batang*, about which, however, travellers have given us but meagre information. It is described as a large town of 200 houses at an elevation of 8000 feet, but of little commercial importance. There are only two Chinese firms at Batang, where the trade is in the hands of the lamas, who, however, make larger profits out of the "pawnbrokers' business" than they do by legitimate trade. Its geographical position near the Dré chu (Yangtse), and its command of the great eastern highroad from China both to Lhasa and to Chinese Turkestan, ensure its vitality. Batang may well be a more important town in the future than it is in the present.

The chief town in the province of Khams is *Chamdo*, which is situated at the junction of two rivers, which are frozen in winter. Here is a large monastery with 3000 priests, and a garrison. European travellers have been jealously kept out of Chamdo lately.

Government.

Though the whole of Tibet is under the suzerainty of China, the government of the country is divided into two distinct administrations, the one under the rule of the Dalai-Lama of Lhasa, the other under local kings or chiefs, and comprising a number of ecclesiastical fiefs. Both are directed and controlled by the high Chinese officials residing at Lhasa, Hsining Fu, and the capital of the Chinese province of Szechuen. North-eastern Tibet or Amdo, and also a portion of Khamdo, are under the supervision of a high official (Manchu) residing at Hsining Fu in Kansu, whose title is Imperial Controller-General of Koko Nor. The native chiefs of the Panaka and other Tibetan tribes of this region are styled *pömbo* ("official" or "headman") by both the natives and the Chinese. The region under the supervision of the Imperial Controller includes all the countries north of the upper course of the Dré chu (Yangtse-kiang). The people pay a small poll-tax to China, and are exempted from any other impost; they also pay a small tax in kind, sheep, butter, &c., to their chiefs. The province of Khamdo, including all eastern Tibet, is governed by local chiefs, styled *gyalbo*, "king," and *déba*, "chief," succession to the chieftainship being usually assured to the eldest son not a lama. Each chief appoints a certain number of civil and military officers to assist in the government of the country, and each village has its headman or *besé*, also a hereditary office. None of these officials receive salaries; they are only exempt from taxation, and some have grants of land made to them. The only tax paid to China is a so-called "horse tax" of about 5d. for each family. Once in every five years the chiefs send a tribute mission to the capital of Szechuen, and once every ten years to Peking, but the tribute sent is purely nominal. The Chinese maintain a few small military posts with from six or eight to twenty men stationed in them; they are under the orders of a colonel residing at Tachienlu. There are also a few lama chiefs.

The part of Tibet under the rule of Lhasa, by far the largest and wealthiest, includes the province of Wu, Tsang, Nari, and a number of large outlying districts in southern and even in eastern Tibet. The central government of this part of the country is at Lhasa; the nominal head is the Dalai-Lama. Under him are five ministers of state (*kalön* or *shapé*), who divide among themselves, under the immediate supervision of the two Imperial Chinese residents (or Amban), the management of all secular affairs of the country. The army is under the high command of the Chinese Amban, a Tibetan generalissimo or *magpön*, and six Tibetan generals or *däpon*. Under the *däpon* are six *rüpon* or colonels, and a number of subordinate officers. The regular army consists

[1] This enumeration of the political divisions of Tibet does not include the elevated steppes of Tsaidam (extending between the Kuenlun and the Altyn Tagh or Nan Shan ranges), inhabited by a mixed race of marauding people, Tunguts and Mongols. Yet Tsaidam is geographically but a northern extension of the great Tibetan plateau, and in most of its essential physical features it is more closely allied to the Changtang of the south than to the great sandy depressions of Chinese Turkestan or Mongolia on the north.

(in theory) of 6000 men, on active service for three years, and at home on half-pay for three years. After the six years they pass into the reserve or militia (*yulmag*). The taxes paid to the Lhasa Government are mostly in kind, sheep, ponies, meal, butter, wool, native cloth, &c., and the coin paid is said to be about 130,000 ounces of silver a year. Chandra Das states that the Crown revenues of Lhasa amount to about 2,000,000 rupees annually. All high Tibetan officials, whether ecclesiastics or laymen, are appointed subject to confirmation by the Chinese Government. The administrative subdivisions of the Lhasa country, of which there are fifty-three, are called *djong*, or "prefecture," each of which is under the rule of two *djongpön*, the one a lama, the other a layman. They collect all taxes, are responsible for the levy of troops, the courier service, corvées, &c., and exercise judicial functions, corresponding directly with Lhasa. There are 123 sub-prefectures under *djongnyer*. Under them are village headmen or *tsopön*, headmen or *mipön*, and elders or *gyanpo*. All are appointed for indefinite periods by the prefects. (For additional data on the administration, revenues, and army see LHASA, and for the religion see LAMAISM, vol. xiv.)

Geology and mineral wealth.

But little is known of the geological structure of the central regions of Tibet. The observations of Strachey or Godwin-Austen, with the more recent observations of Griesbach and other members of the Geological Survey of India, only extend to the southern edge or rim of the great plateau where vast alluvial deposits in horizontal strata have been furrowed into deep ravines, whilst Russian explorers have as yet but superficially examined the mountain regions of the north and north-east.

The general structure of the trans-Himalayan chains appears to indicate that the main axis of upheaval of the whole vast mass of the Tibetan highlands is to be found on two approximately parallel lines, represented the one by the Kuen-lun, and the other by a line which is more or less coincident with the watershed between India and the central lake region, extending from Lake Pangong to Tengri Nor, the plateau enclosed between the two being wrinkled by minor folds, of which the relative elevation is comparatively low, averaging from 1000 to 1500 feet. The strike of these folds is usually east and west and roughly parallel to the axes of elevation of the plateau. A very remarkable economic feature is the almost universal distribution of gold throughout Tibet. Gold has been worked on the plateau for numberless centuries. The gold-digging is referred to in somewhat mythical terms by Herodotus. Every river which rises in Tibet washes down sands impregnated with gold, and it has been proved that this gold is not the product of intervening strata, but must have existed primarily in the crystalline rocks of the main axes of upheaval. In western Tibet the gold mines of Jalung have been worked since 1875. They have been visited by native explorers of the Indian Survey, who reported that much gold was produced therefrom, and that it was remitted twice a year under a Chinese guard to Peking. The Tibetan diggers collected together at the mines chiefly during the winter, when the frost assisted to bind the loose alluvial soil and render excavation easy. These mines are within 200 miles of the Ladak frontier, near the sources of the Indus, at an elevation which cannot be less than 15,000 feet above sea-level. They are said to have been lately abandoned owing to the exorbitant imposts levied on gold production by Chinese and Tibetan officials. Between the Ladak frontier and Lhasa the plateau region teems with evidences of disused and abandoned mines, which might be counted by hundreds. These mines are excavations in the alluvial soil, never more than from 20 to 30 feet deep, and the gold produced therefrom has been separated from the soil by a process of washing so crude that a great part of it must inevitably have been lost.

The researches of Prjevalsky demonstrate that gold is plentiful in northern and eastern Tibet. Here Tungus diggers were encountered who had extracted handfuls of gold in small nuggets from a stream bed at a depth which they stated to be no greater than 2 feet. Another scientific explorer, Mr W. Mesny, has observed similar evidences of the existence of gold at comparatively shallow depths in Koko Nor region, and records that he has seen nuggets, "varying from the size of a pea to that of a hazel-nut," in eastern Tibet. The gold was almost pure and perfectly malleable. The Gork goldfields, which are visible from Koko Nor, are reported to have yielded to China very considerable quantities of gold as lately as 1888. They are now deserted. Prjevalsky, indeed, predicts of northern Tibet that it will prove a "second California" in course of time. But very little gold at present finds its way across the Tibetan passes to India, either by way of Ladak or Kumaon; and the export to China has diminished of late years. Until the determined official opposition to exploration, which is maintained both by Chinese and Tibetan authorities, is sufficiently relaxed to admit of the presence of European experts, it will be impossible to estimate the economic value of the enormous area of the Tibetan goldfields which are already known to exist.

Iron is found in eastern Tibet in the form of pyrites, and is rudely smelted locally. Salt and borax exist in abundance in the western lake regions. The exportation of borax to India is only limited by the comparatively small demand. Lapis-lazuli and quicksilver are amongst the minor mineral products of the country, which is, however, but very partially exploited.

Climate.

The climate of Tibet varies so greatly over the enormous area and the changing altitudes of the country, that no two travellers agree precisely in their records. Tibet is affected by the south-west monsoon, just as the Pamirs are affected, but in varying degrees according to geographical position. In western Tibet, bordering the Kashmir frontier, the climate differs but little from that of Ladak. Intense dryness pervades the atmosphere during nine months of the year; but little snow falls, and the western passes are so little subject to intermittent falls of fresh snow, as frequently to be traversable during the whole year round (see LADAK). Low temperatures are prevalent throughout these western regions, whose bleak desolation is unrelieved by the existence of trees or vegetation of any size, and where the wind sweeps unchecked across vast expanses of arid plain. All the western region is but slightly affected by the monsoon. The central lake region, extending from the Kuen-lun to the Himalaya, is also characterized by extreme dryness in autumn, winter, and spring, with an abundance of rain in summer, whilst the eastern mountain region, extending to China south of the Dang la (which, with an altitude of about 20,000 feet, stretches from 90° to 97° E. along the parallel of 33° N., and arrests the monsoon currents), is subject to much the same climatic influences as the eastern Himalaya. The southern slopes of the Dang la are deluged with rain, hail, and snow throughout the year. Northern Tibet is an arid waste, subject to intense heat in summer and intense cold in winter. In March snow still lies deep in the Tsaidam passes, whilst Wellby found the heat oppressive in June at 16,000 feet elevation on the plateau south of the Kuen-lun, and a temperate climate prevailing about the sources of the Dré chu (Yangtse) in August.

All travellers testify to the perpetual wind currents from the west, which sweep with fierce, unremitting blasts across the salt bogs of Tsaidam (9500 feet) and through the higher valleys of eastern Tibet. Wind is a prevailing feature throughout Tibet at certain seasons of the year, as it is in the Pamirs, in Turkestan, in western Afghanistan, and in Persia. The climate of southern Tibet is, however, subject to considerable modifications from that of the northern and central regions, owing doubtless to its geographical connexion with northern India. Here, at an elevation of 15,000 feet, about the great Lake Dangra, we hear of well-built villages and of richly cultivated fields of barley, indicating a condition of climate analogous to that which prevails in the districts south of Lhasa, and in sharp contrast to the monotonous sterility of the lake region generally and the nomadic character of its population. Recent travellers bear witness to a gradual progress of desiccation in the Tibetan uplands. Everywhere there are signs of the gradual diminution of the lakes and the recession of the water line—a phenomenon that has also been observed in the Pamirs. There are still enormous glaciers about the head of the Brahmaputra, but the glacial epoch of the Changtang highlands has passed away; but it has passed comparatively recently, and the last evidences of its existence are to be traced in those lakes, which are now in their turn slowly disappearing. There is nothing to be found in the records of recent exploration or travel to indicate that in western, southern, or eastern Tibet the climate of the winter months is of a severity which would render it inimical to European existence.

Flora.

Our knowledge of the flora of northern and central Tibet has been considerably increased by the collections of Prjevalsky, Wellby, Bower, and Littledale, and that of eastern Tibet by Rockhill. These and other collections have been admirably described in W. B. Hemsley's *The Flora of Tibet or High Asia*. Western and southern Tibet were fairly well explored previously to the advent of these travellers. Professor Maximowicz concludes from an analysis of the Prjevalsky collection that the flora of Tibet is extremely ancient, and that it is chiefly composed of immigrants from the Himalaya and Mongolia. There is also a large percentage of endemic species. Chinese and European plants followed in the process of immigration. Those species which are distinctive of the eastern border ridges are found to reach the plateau, but do not spread westwards, so that a

botanic separation or distinction is found to exist between the true plateau of Tibet in the west and the alpine tracts of the east. Thiselton-Dyer classes the flora of Tibet on the whole as belonging to the Arctic-Alpine section of the great northern division, but containing a purely endemic element. Two typical species are *Lychnis apetala*, which extends to Spitsbergen, and the well-known edelweiss. A single fern specimen obtained by Littledale (*Polypodium hastatum*) is indicative of eastern China. Of the forty or fifty genera obtained by Littledale in central Tibet, a very large proportion are British, including many of the most characteristic mountain forms. In the higher regions of northern and western Tibet the conditions under which vegetation exists are extreme. Here there are no trees, no shrubs, nor any plants above a foot high. Wellby says he saw nothing higher than an onion. The peculiar form of tussocky grass which prevails in the Pamirs is the characteristic feature of the Tibetan Changtang of the Tsaidam plains and of the bogs north-east of Lhasa. Of grasses indeed there are many forms, some of them peculiar to Tibet, but no trees or shrubs at any elevation higher than 15,000 feet. A flowering plant (*Saussurea tridactyla*) was discovered by Bower at an elevation of 19,000 feet. In south-eastern Tibet, where Himalayan conditions of climate prevail, we have a completely different class of flora. Of the flora of Tibet Mr Rockhill writes: "In the 'hot lands' (*tsa-rong*) in southern and south-eastern Tibet, extending even to Batang, peaches, apricots, apples, plums, grapes, water-melons, &c., and even pomegranates, are raised; most of Tibet only produces a few varieties of vegetables, such as potatoes, turnips, beans, cabbages, onions, &c. The principal cereals raised are barley and buckwheat, wheat in small quantities, and a little oats. A few localities in the extreme southern portions of the country, and around Lhasa possibly, are said to produce a non-glutinous variety of rice. A variety of mountain bamboo is found in southern and parts of eastern Tibet, and is much used for basket work. Tibet produces a large number of medicinal plants much prized by the medical profession in China and Mongolia, among others the *Cordyceps sinensis*, the *Coptis teeta*, Wall., and *Pickorhiza kurroa*, Royle, &c. Rhubarb is also found in great quantities in eastern Tibet and Amdo; it is largely exported for European use, but does not appear to be used medicinally in the country. The trees most commonly found are the plane, poplar, maple, walnut, oak, the *cupressus funebris*, and various varieties of the genera *pinus*, *abies*, and *larix*. Some valuable plants are obtained in the mountains of south and south-western Tibet, yielding the excellent yellow and red colours used to dye the native cloths."

The fauna of Tibet has been by no means exhaustively investigated, especially the rodents and smaller species of animals.

Fauna. Amongst domesticated animals are to be found the horse, mule, donkey, cattle, sheep and goats, fowls and pigs, ducks and geese. Probably no country in the world, excepting perhaps inner Africa, so abounds in wild animals as the cold solitudes of the northern plateau. Here are to be found yak, wild asses (*kiang*), several varieties of deer, musk deer, and Tibetan antelope (*pantholopo*); also wild sheep (the *burret* of the Himalaya), *Ovis ammon* and possibly *Ovis poli*, together with wild goats, bears (in large numbers in the north-eastern districts), leopards, otter, wolves, foxes, marmots, monkeys, squirrels, and wild dogs. To this list must be added the curious *Ailuropus melanoleucus*. Birds are fairly numerous, and include many varieties of water-fowl, some of which (*Anser indicus* [the bar-headed goose], for instance) breed in Tibet, whilst others are only found as birds of passage. In eastern Tibet, on the Chinese border, varieties of the pheasant tribe abound, some of which are rare. Amongst them are the "white" pheasant, the *Ceriornis Temminckii*, two kinds of eared pheasant, Anderson's pheasant, and the blood pheasant. The Tibetan sand-grouse is peculiar to the country, and the snow-partridge (a member of the Himalayan variety) is also occasionally met with. Wellby mentions eagles in the north-east of the plateau, and Rockhill enumerates, on Chinese authority, storks, larks, and swallows amongst the birds of central Tibet.

The industries are confined to the manufacture of woollen cloth of various degrees of fineness and colour, and called *truk*, *tirma*, and *lawa*, to that of small rugs, pottery of an inferior quality, utensils of copper and iron, some of which show considerable artistic skill in design, and to such other small trades as are necessary to supply the limited wants of the people. The best artisans are Nepalese and Chinese, the former being the best workers in metal and dyers.

Industries and trade.

The great trade routes are, first, that which, starting from Cheng-tu, the capital of the Chinese province of Szechuen, passes by way of Tachienlu, Litang, Batang, Chamdo, Larego, Lhasa, Gyantsé, Shigatsé, reaches the Nepalese frontier at Nielam and goes thence to Khatmandu. This route is called *Gya-lam*, "the China road" (or "high road"); the great bulk of Tibetan travel goes over it. Minor roads go from Hsining Fu in the Chinese province of Kansu *viâ* Tsaidam and the Dang la pass to Nagchuka and Lhasa. This road, called the *Chang lam* or "northern road," was much used by traders till the middle of the 19th century, since when the Mahommedan rebellions in north-western China have practically closed it. Another road starts from Sung-pan in north-western Szechuen, and, by way of the sources of the Yellow river, joins the Gya-lam at Chamdo; it is but little used, as it passes through the country of the wild marauding Golok. Still another route starts from Tachienlu, and by the valley of the Yalung and the Dré chu runs to Gyékundo, and thence to Chamdo. From this point it leads to Riwoche, and then through Gyade or Chinese province to Nagchuka and Lhasa. An important trade road starts from Likiang Fu in Yunnan, and by way of Chung-tien (Guiedam of the French missionaries) joins the Gya-lam at Batang.

Internal communication.

The latest routes adopted by travellers from Darjiling to Lhasa have been those which, avoiding the Chumbi valley, have crossed the Himalaya on the north-west rather than the north-east of Sikkim, and run most directly to Shigatsé. From Shigatsé to Lhasa the route has been the same as that followed by Nain Sing in earlier days, which passes by Gyantsé and thence over the lofty Kharo la plateau through the lake basin of the Yamdok tso, across the Khambala range to the Nari chu (Tsanpo). Between Shigatsé and the mouth of the Kyi chu (on which Lhasa stands) there is still no direct communication by river. Chandra Das, travelling *viâ* Kambajong and the Kongra Lamo pass, made a twenty-eight days' journey between Shigatsé and Darjiling. The direct distance being about 160 miles, this length of time is sufficient indication of the tortuous and difficult nature of the mountain track. From Khatmandu, the capital of Nepal, a difficult mountain route runs by Kirong tso to the No la (16,600 feet), descending from which pass it strikes the Tsanpo about midway between Lhasa and Lake Mansarowar. Farther west Tibet may be reached from Kumaon by one of a group of passes (of which the best-known is the Milam) leading to Lake Mansarowar. The lake becomes a sort of obligatory point on all routes to Tibet which lie between Ladak and Nepal. The Shipki road from Simla, which strikes the Sutlej at Totling (where there is a bridge), leads up to Mansarowar, coinciding with the great high-road (*Jonglam*) after passing Totling. The Jonglam (elsewhere called Gya-lam, which traverses the whole length of Tibet from Leh to China) is the route by which Chinese officials keep up communication with western Tibet. From Leh to Gartok (14,250 feet) it follows the upper Indus valley; then crossing the lofty Kailas range (dividing the Indus from the Sutlej) it drops to Totling and follows the Sutlej to Mansarowar. The remarkable area of gold-mining industry which lies to the north-east of Gartok is reached by another route from Leh, which, crossing the Chang la close to Leh, passes by Rudok at the eastern extremity of Lake Pangong in a south-easterly direction, running north of the great mountain masses which crowd round the Indus sources. It continues through the central lake district of the Hor province to Tengri Nor and Lhasa.

Trade routes, &c.

For the money of Tibet see the article LHASA. The weights and measures in use are practically those of China; the dry measures, the most commonly employed, are the *bré* or *bo* of about four pints and the *bchal* of twenty *bo*; the capacity of the *bo* varies according to localities. The most commonly used measures of length are the span (*mto*), the cubit (*kru*), and the arm's-length or fathom (*dompa*).

Currency.

The principal trade with the outside world is carried on with China over the Lhasa–Tachienlu road. Mr G. L. Litton, of H.B.M. Consular Service in China, in his report on the nature and value of this trade in 1898, gives the following figures for the average value passing through Tachienlu:—

Foreign trade.

Exports from Tibet.

	Value, Taels.	Total Taels.
Musk	500,000	
Wool	200,000	
Gold	150,000	
Fox skins	25,000	
Other skins	30,000	
Rhubarb and drugs	30,000	
		935,000

Imports to Tibet.

Tea	1,100,000	
Cottons	10,000	
Silks and sundries	40,000	
		1,150,000
		2,085,000

The value of the Chinese tael is 1⅓ oz. avoirdupois of silver by treaty. The tea imported from Szechuen is for the most part of very inferior quality, estimated at 35 per cent. tea-leaves and 65 twigs and other material. It is compressed into large bricks, and costs two-thirds of a penny per pound. No Indian tea would compete with it. Tachienlu is the principal market, permits being issued each year from Peking to the traders. The trade between Sung-pan in north-west Szechuen and Tibet is estimated by the same writer as follows:—

Imports to Tibet.	Value, Taels.	Total Taels.
Tea	760,000	
Cotton and woollen goods	15,000	
Brass and ironware, and sundries	5,000	
		780,000
Exports from Tibet.		
Wool	80,000	
Live sheep	20,000	
Sheepskins and furs	180,000	
Medicines and musk	520,000	
		800,000
		1,580,000

The trade carried over the Hsining-Tankar-Tsaidam route has not been large for many years, on account of the various Mahommedan rebellions in Kansu. Probably the value of the exports and imports over it cannot be estimated at more than 50,000 to 75,000 taels a year, including in this the value of the Mongol trade. Trade between India and Tibet is carried on at present over the road which, starting from Darjiling, crosses the Jelap la and passes by Yatung, the Chumbi valley to Khamba djong, Shigatsé, and Lhasa. Yatung (80 miles from Darjiling) was opened 1st May 1894 to foreign trade under the regulations appended to the Sikkim-Tibet Convention of 1890, concluded between the Viceroy of India and the Chinese Amban of Lhasa. An officer of the Chinese Maritime Customs is stationed at Yatung; beyond this point foreigners are not allowed to proceed. The trade over this route has steadily grown since the opening of the road. The gross value of the imports into and exports from Tibet is as follows:—

	1897.	1898.	1899.	1900.
	Rupees.	Rupees.	Rupees.	Rupees.
Imports	674,139	718,475	962,637	730,502
Exports	820,300	817,851	822,760	710,012
Total	1,494,439	1,536,326	1,785,397	1,440,514

The total imports into British India from Tibet by all available routes are more than double the value enumerated above according to the Indian official statistics of 1898. This would allow a considerable margin for the trade *viâ* Ladak and across the Kumaon passes. Returns for the official year ending 31st March 1901 give the value of the trade between Bengal and Tibet as 6·20 lakhs of rupees. The exports consist mostly of wool, woollen cloths, musk, yaks' tails, skins, ponies, and mules. The imports comprise a large variety of articles, principally cotton and woollen goods, silks, metals, tobacco, umbrellas, matches, kerosene, clocks, watches, and quite a large quantity of Chinese goods shipped from China to Calcutta, and thence by rail to Darjiling. Tibetan woollen goods are also exported over this route to be taken to Peking by sea. No tea is allowed by the Chinese to be brought into Tibet over this road. The value of the trade between Bhutan and Tibet is not known. The native explorer E. N. states (in 1886) that "the exports from Tibet (into Bhutan) are chiefly salt, blankets, wool, skins, tea in bricks, musk pods, and earthen pots, of which salt and wool take the first place with regard to quantity exported. These are either sold for cash in the currency of Tibet, or are bartered for the following commodities, viz., *buré* (a kind of silk stuff), *khamar* (coloured silk), *yultha* (a cotton cloth), brass utensils, silver, jewellery, rice, and tobacco." Trustworthy statistics of the value of the trade maintained between Tibet and bordering countries are not obtainable. Probably the trade with Bhutan does not much exceed Rs.10,000 in value. Trade with Ladak (independent of that which passes through Leh to India) is inconsiderable, and is certainly exceeded in value by the trade with Nepal. The total foreign trade of Tibet does not probably exceed Rs.10,000,000 a year.

(T. H. H*.; W. W. R.)

Tichborne Claimant, The.—Roger Charles Tichborne (1829–1854), whose family name became a household word on account of an attempt made by an impostor in 1868 to personate him and obtain his heritage, was the eldest grandson of Sir Edward Tichborne, the 9th baronet, of a very ancient Hampshire family. Sir John de Tichborne, sheriff of Southampton, was created a baronet by James I. in 1621, and from him his descendants inherited great wealth and the position of one of the leading Roman Catholic families in the south of England. Roger Charles, born at Paris on 5th January 1829, was the eldest son of James Francis Doughty-Tichborne (who subsequently became 10th baronet and died in 1862) by Henriette Felicité, natural daughter of Henry Seymour of Knoyle, in Wiltshire. This lady, who hated England, was intent upon bringing up her son as a Frenchman: the result was that he hardly got any education at all until he went in 1846 to Stonyhurst, whence he proceeded in 1849 to Dublin and joined the 6th Dragoon Guards. His eccentricity and his French accent made him rather a butt in his regiment, and, being disappointed of war service, he sold out in 1852, and in the following year proceeded on a trip to South America. He sailed in March 1853 from Havre for Valparaiso, whence he crossed the Andes, reaching Rio in 1854. In April of that year he sailed from Rio in the *Bella* and was lost at sea, the vessel foundering with all hands. His insurance was paid and his will proved in July 1855. The baronetcy and estates passed in 1862 to Roger's younger brother, Sir Alfred Joseph Doughty-Tichborne, who died in 1866. The only person unconvinced of Roger's death was his mother, the dowager Lady Tichborne, from whom every tramping sailor found an eager welcome at Tichborne Park. She advertised largely and in a highly injudicious manner for the long-lost wanderer, and in November 1865 she learnt, through an agency in Sydney, that a man "answering to the description of her son" had been found in the guise of a small butcher at Wagga Wagga, in Queensland. As a matter of fact, the supposed Sir Roger did not correspond at all to the long-lost heir, who was slim, with sharp features and straight black hair, whereas the claimant was enormously fat, with wavy, light brown hair. His first letter to Lady Tichborne was not only ignorant and illiterate to the last degree, but appealed to circumstances

(notably a birth-mark and an incident at Brighton) of which she admitted that she had no recollection. But so great was her infatuation with her fixed idea, that she soon overcame the first qualms of distrust and advanced money for the claimant to return to Europe. Like all pretenders, this one was impelled by his *entourage*, who regarded him strictly in the light of an investment. He himself was reluctant to move, but the credulity of persons under the influence of a romantic story soon came to his aid. Thus an old friend of Sir James Tichborne's at Sydney, though puzzled by the claimant's answers, was quite convinced by a resemblance to his supposed father, "especially about the mouth." At Sydney, too, he made the acquaintance of Bogle, a negro servant of a former baronet. Bogle sailed with him from Sydney in the summer of 1866, and coached him in the rudiments of the rôle which he was preparing to sustain. On reaching London on Christmas Day 1866 the claimant paid a flying visit to Tichborne House, near Alresford, where he was soon to obtain two highly important allies in the old family solicitor, Mr Hopkins, and a Winchester antiquary named Baigent, who was intimately acquainted with the Tichborne family history. He next went over to Paris, where in a hotel bedroom on a dark January afternoon he was promptly "recognized" by Lady Tichborne. She had formerly been a beauty, and her real son had borne a striking resemblance to her. The claimant was an unwieldy "mass of flesh," scaling nearly 25 stone, and his countenance was of a repulsive coarseness. This "recognition" naturally made an enormous impression upon the English public, who were unaware that Lady Tichborne was a monomaniac. That such a term is no exaggeration is shown by the fact that she at once acquiesced in her supposed son's absolute ignorance of French. She allowed the claimant £1000 a year, accepted his wife, a poor illiterate girl, whom he had married in Queensland, and handed over to him the diaries and letters written by Roger Tichborne from South America. From these documents the claimant now carefully studied his part; he learnt much, too, from Baigent and from two carabineers of Roger's old regiment, whom he took into his service. The villagers in Hampshire, a number of the county families, and several of Tichborne's fellow-officers in the 6th Dragoons, became eager victims of the delusion. The members of the Tichborne family in England, however, were unanimous in declaring the claimant to be an impostor, and they were soon put upon the track of discoveries which revealed that Tom Castro, as the claimant had been called in Australia, was identical with Arthur Orton (born 1834), the son of a Wapping butcher, who had deserted a sailing vessel at Valparaiso in 1850, and had received much kindness at Melipilla in South America from a family named Castro, whose name he had subsequently elected to bear during his sojourn in Australia. It was shown that the claimant, on arriving in England from Sydney in 1856, had first of all directed his steps to Wapping and inquired about the surviving members of his family. It was discovered, too, that Roger Tichborne was never at Melipilla, an assertion to which the claimant, transferring his own adventures in South America to the account of the man whom he impersonated, had committed himself in an affidavit. These discoveries and the deaths of Lady Tichborne and the friendly solicitor, Hopkins, were so discouraging that the "claimant" would gladly have "retired" from the baronetage; but the pressure of his creditors, to whom he owed vast sums, was importunate. A number of "Tichborne bonds" to defray the expenses of litigation were taken up by the dupes of the imposture, and an ejectment action against the trustees of the Tichborne estates (to which the heir was the present baronet, Sir Henry Alfred Joseph Doughty-Tichborne, then two years old) finally came before Chief Justice Bovill and a special jury at the Court of Common Pleas on 11th May 1871. During a trial that lasted over one hundred days the claimant exhibited an ignorance, a cunning, and a bull-dog tenacity in brazening out the discrepancies and absurdities of his depositions, which have probably never been surpassed in the history of crime; they may have been rivalled in the case of Titus Oates, to whom in physical constitution the claimant bore a striking resemblance. Over one hundred persons swore to the claimant's identity, the majority of them, and they were drawn from every class, being evidently sincere in their belief in his cause. It was not until Sir John Coleridge, in a speech of unparalleled length, laid bare the whole conspiracy from its inception, that the result ceased to be doubtful. The evidence of the Tichbornes finally convinced the jury, who declared that they wanted no further evidence, and on 5th March 1872 Serjeant Ballantine, who led for the claimant, elected to be nonsuited. Orton was immediately arrested on a charge of perjury, and was brought to trial at bar before Chief Justice Cockburn in 1873. The defendant showed his old qualities of impudence and endurance, but the furious indiscretion of his counsel, Edward Kenealy, the testimony of his former sweetheart, and Kenealy's refusal to put the Orton sisters in the box, proved conclusive to the jury, who, on the one hundred and eighty-eighth day of the trial, after half-an-hour's deliberation, found that the claimant was Arthur Orton. Found guilty of perjury on two counts, he was sentenced on 28th February 1874 to fourteen years' penal servitude. The cost of the two trials was estimated at something not far short of £200,000, and of this the Tichborne estates were mulcted of fully £90,000. The claimant's better-class supporters had deserted him before the second trial, but the people who had subscribed for his defence were staunch, while the populace were convinced that he was a persecuted man, and that the Jesuits were at the bottom of a deep-laid plot for keeping him out of his own. There were symptoms of a riot in London in April 1875, when Parliament unanimously rejected a motion (by Kenealy) for referring the Tichborne case to a royal commission, and the military had to be held in readiness. But the agitation subsided, and when Orton emerged from gaol in 1884 the fickle public took no interest in him. The sensation of ten years earlier could not be galvanized into fresh life either by his lectures or his alternate confessions of imposture and reiterations of innocence, and Orton sank into poverty and oblivion, dying in obscure lodgings in Marylebone on 2nd April 1898. (T. SE.)

Ticino, or TESSIN, one of the Swiss cantons. Its area is 1087·9 square miles. Of this 725·67 square miles are "productive," forests covering 233·8 square miles, and vineyards 30·7 square miles (the greatest vine-growing area in Switzerland), the remaining 461·1 square miles being arable or meadow land. The population was 126,751 in 1888, while in 1900 it was 138,638, or 127 inhabitants per square mile. The canton is overwhelmingly Romanist and Italian-speaking. In 1888 the episcopal see of Lugano was founded: it is at present held by the bishop of Basel, who names an administrator apostolic for Ticino. Bellinzona is now the only political capital, but the largest town in the canton is Lugano. In 1888 Locarno had 3142 inhabitants (3557 in 1900), Airolo 1697 (in 1900, 1629), and Mendrisio 2815 (in 1900, 3441). The canton is divided into seven administrative districts. In 1897 its state revenue was 3,891,293 francs (a rise of 63 per cent. since 1885), and the state expenditure

3,733,263 francs (a rise of 97 per cent. since 1885), but in 1898 there was a deficit of 110,102 francs. In 1897 the public debt was 13,235,208 francs.

The political troubles of Ticino were increased in 1888 by the foundation of the see of Lugano, considered by the Radicals as likely to advance Clericalism, though it freed Switzerland from foreign ecclesiastical rule. Hence in September 1890 the Radicals carried out a bloody revolution, which necessitated Federal intervention, but at a state trial at Zürich in July 1891 the leaders were acquitted. In 1891 proportional representation was adopted for elections for the cantonal and communal assemblies. In 1892 a new cantonal constitution was accepted, by which the executive is elected directly by the people, and proportional representation is maintained, while the Facultative Referendum, especially for certain financial bills, and an initiative in legislative matters, are given to 5000 citizens, though 7000 are required in the case of an amendment in the cantonal constitution. In 1896, by a strange anomaly only to be explained by the previous political history of the canton, non-resident citizens were given a vote in all cantonal and communal matters, though residence is strictly required for all voters in Federal matters.

Tides.—Our knowledge of the tides has been advanced in several ways since the date of the ninth edition of this Encyclopædia. From the nature of the case the following sections do not form part of a connected whole; they are rather a collection of minor articles dealing with topics connected with the tides.

The subjects treated are:—

§ 1. Seiches, or oscillations in lakes.
§ 2. The bore in estuaries.
§ 3. The deflection of the vertical by lunar attraction.
§ 4. Tide-tables and tidal prediction.
§§ 5–10. Recent advances in the dynamical theory of the tides.

Occasion will frequently arise to refer to the article in the ninth edition of this work (vol. xxiii. pp. 353–381); we shall for brevity call it TIDES. Where it may be necessary to give a reference to a book entitled *The Tides and Kindred Phenomena in the Solar System*, by G. H. Darwin (John Murray, 1898), it will be referred to as Darwin's *Tides, &c.*

§ 1. *Seiches.*

In the article TIDES (p. 370) there is reproduced a portion of a tide-curve for Bombay. The object of the figure was to show the general nature of tidal oscillations, and accordingly certain small irregularities, which probably existed in the original, were smoothed out. Such irregularities are found in most tide-curves, and the smoothing of this curve has masked an interesting phenomenon closely connected with the tides, although arising from a wholly different set of causes.

Irregularities in tide-curves.

The notches which are prevalent in tide-curves indicate that the water is affected by other waves than that of the main tide. These secondary waves are observed to have periods which range from two to twenty minutes; they thus alternate very much more rapidly than does the tide, whilst their periods are very much longer than those of the waves which are visible on the surface of the sea. Waves of this kind have sometimes been called periodic tides—as, for example, in correspondence in *Nature* on 12th January and 20th April 1899; but the name is altogether inappropriate, since they are not tides, and they possess the attribute of periodicity in common with all other waves.

In order to gain some insight into the nature of the phenomenon, we must now turn our attention to certain observations which have been made on an inland lake.

Seiches on Lake of Geneva.

It has been known for several centuries that the water of the Lake of Geneva is apt to rise and fall by a few inches, sometimes irregularly and sometimes with more or less regularity. Since the water ebbs and flows, these oscillations present some resemblance to true tides, and the phenomenon is sufficiently conspicuous to have gained from the inhabitants of the shores of the lake the name of Seiche. It was discovered during the last half of the 19th century that these waves are not peculiar to the basin of Geneva, and the name seiche has been generally adopted, whether we speak of the waters of a lake or of a land-locked arm of the sea.

In the 18th century Fatio de Duillier recorded a celebrated seiche which occurred in the year 1600 on the Lake of Geneva, when the range of the wave from lowest to highest was 5 feet 4 inches; but the first man thoroughly to investigate the subject was Dr Forel of Lausanne.[1] Between the years 1876 and 1885 he published, principally in the *Archives des Sciences Physiques et Naturelles* of Geneva, a series of papers giving the results of his observations. An abstract of these papers, with illustrative diagrams, is given in Darwin's *Tides, &c.*

Forel observes and analyses Genevan Seiches.

At first Dr Forel conducted his observations by means of a simple but very sensitive apparatus, called by him a plemyrameter, which was intended to detect the periodicity of the oscillations of the water without reference to the heights of the waves. By the observation of a light float in a horizontal glass tube, which formed portion of a pipe connecting the water in the lake with that in a tank ashore, he was able to detect even the slightest current setting from the lake to the tank, or *vice versâ*. Such a current was found to occur even when the difference of levels amounted to only a fraction of a millimetre. Care was of course taken, by choking the ingress of the water into the pipe, to obliterate the effect of the visible waves and ripples on the lake, so that his attention was directed only to inequalities with a duration of at least a minute. A description of the instrument and of the records derived by means of it is contained in Dr Forel's book, and in chapter ii. of Darwin's *Tides, &c.*

A careful study of the registrations of his instrument, taken at Morges and at other places, convinced Dr Forel that the oscillations were not irregular and capricious, as they naturally appear to the casual observer. He was able, in fact, to pick out from the complex motions several rhythms which presented themselves over and over again on many occasions. It will easily be perceived that the coexistence of several rhythmical movements, presenting themselves in various intensities and in various phases relatively to one another, suffices to explain any amount of complexity in the aggregate effect.

Dr Forel then concluded that these motions are oscillations dependent on the shape and depth of the whole lake, and he announced that seiches are due to "a gigantic impulse moving the whole liquid mass of Leman throughout its length, breadth, and depth." He adds that "it is probable that the same thing would be observed in far larger basins of water."

He concluded that the principal oscillations are of two kinds, the longitudinal and the transverse. In the seiche of longest period the water was found to rock about a line drawn transversely across the lake at its centre, so that it was high water at Villeneuve when it was low

[1] His papers are collected in *Le Léman*, 2 vols. (Roux, Lausanne, 1892).

water at Geneva, and conversely. Such a seiche is said to be uninodal and longitudinal, because it affects the whole length of the lake, and there is at the centre a node or place at which the water is stationary as to height. He found that seventy-three minutes elapsed between successive high waters at either end of the lake, and that this period was the same whether the seiche was of visible amplitude or whether it amounted to only a fraction of a millimetre.

A crucial test of the correctness of Dr Forel's analysis is afforded by the determination of the period of oscillation of water in a trough of the dimensions of the Lake of Geneva in accordance with the laws of moving liquid. Now it may be concluded from this consideration that if it were possible to tilt up one end of the lake, so as to make the water rock about a single central node, the period of the oscillation would be very nearly that which was observed. The irregularities in the bed of the lake are, of course, considerable, and the period cannot be determined by *à priori* reasoning with close accuracy, but the discussion demonstrated with certainty the nature of the motion in the case of these seiches of longest period.

If the uninodal longitudinal seiche had been the only motion of the water, Dr Forel's task would have been a comparatively easy one, but, as has been already said, the motion is in reality exceedingly complex. He was, however, also able to show the existence of the binodal seiche with a period of thirty-five minutes. In this case there are two nodes which divide the lake into three parts, of which the two terminal ones are each half as long as the central part. In this kind of seiche the low water occurs simultaneously at the two ends when it is high water at the centre. The existence of multinodal longitudinal seiches was also suspected, although the complication was so great as to prohibit absolute demonstration. Besides these longitudinal oscillations, uninodal transverse seiches were picked out with certainty. In this case the water was highest at Morges on the north when it was lowest at Évian on the south, and the period was determined at about ten minutes. It was thus established that the whole water of the lake is apt to oscillate about several fixed longitudinal or transverse nodes, but the question remained as to the manner in which the motions originate. Any cause which tends to heap up the water at one end or at one side of the lake, and then ceases to operate, must start an oscillation which will last for many hours, with gradually decreasing amplitude, until the motion finally dies out in consequence of friction. Dr Forel suggested that such a temporary local rise of water-level may be produced in various ways. Some, perhaps many, seiches are due to the tilting of the whole lake-bed by minute movements of the earth's surface. Modern investigations seem to show that this is probably a more fertile cause than Dr Forel was disposed to allow.

Longitudinal and transverse Seiches.

When the wind blows in one direction for many hours it heaps up the water to leeward, and when it drops a seiche must necessarily originate. Again, the height of the barometer will often differ slightly at different parts of the lake, and the water must respond to the atmospheric pressure at the rate of about a foot of water to an inch of mercury: we shall return to the consideration of this point hereafter. Dr Forel also suggested that a seiche was most frequently the result of a sudden squall, but we think that he much over-estimated the efficiency of this cause. It is thus possible to point out several causes competent to produce seiches, but it generally remains impossible to say how any particular seiche was started.

Their causes.

Before leaving this subject, it may be well to mention that some observations have been made on other lakes, and we may especially refer to the observations of seiches on Lake George in New South Wales, made by Mr Russell, Government Astronomer at Sydney.[1]

We commenced this discussion by referring to the notches on tide-curves, but these zigzags are in general too rapid to be entirely attributable to the seiches of a land-locked arm of the sea. There must, then, be other oscillations besides seiches, and Dr Forel found that this was also true of the Lake of Geneva. These oscillations resembled seiches in every respect except in the greater rapidity of their alternations. Some of them were perhaps multinodal seiches, but they frequently only affected a portion of the lake at a time. In order to distinguish them from proper seiches, he called them "vibrations."

In all his later work Dr Forel replaced his plemyrameter by a very sensitive form of tide-gauge which he called a limnimeter. The trace was registered on a very open scale, so that an interval of a minute was clearly legible. This would not be the case with an ordinary tide-curve. He found then that, when there is much wind, vibrations make their appearance which are quite distinct from ordinary wave motion, inasmuch as their periods range from forty-five seconds to four minutes. It is probable that there is a complete gradation of waves extending from the shortest ripple up to vibrations with a period of four or five minutes. However this may be, the form of instrument adapted for the observation of short waves would be quite different from one appropriate for waves with a period a hundred times as great, and thus the consideration of vibrations naturally separates itself from that of waves.

Vibrations of lakes due to wind.

Dr Forel found that the wind always produced vibrations, and that it was most efficient when it blew from certain definite directions; but he also found that steamers produced movements so closely resembling those due to wind, that it was only possible to study the wind-vibrations at night, when there were no steamers plying on the lake, and the steamer-vibrations in calm weather. As a steamer is approaching the place of observation the vibrations become visible on the trace of the limnimeter as much as twenty-five minutes before its arrival, and they continue to be visible during two to three hours after the boat has passed. The antecedent vibrations have a shorter period of oscillation than the subsequent ones. The lengths of these waves may be concluded from their periods, and it appears that they may be from 1000 yards to a mile in length, and are therefore quite distinct from the visible waves generated by the boat as it ploughs through the water. Dr Forel gives a trace of the limnimeter as affected by these steamer-vibrations in his paper "Les Seiches" (*Annales de Chimie et de Physique*, 1876); this figure is reproduced in chapter ii. of Darwin's *Tides*, &c.

Vibrations due to steamers.

Dr Forel was aware that similar vibrations exist in the sea, and he remarks that they cannot be due to seiches if these are defined as oscillations of the whole sheet of water about fixed nodes. It appears to us probable, however, that true seiches do occur in land-locked harbours or estuaries, since the seaward opening may often be narrow enough to make the water oscillate almost as though the mouth of the harbour were completely blocked. It seems almost certain, then, that the zigzags observable in tide-curves are due partly to seiches proper to the harbour and partly to vibrations.

Seiches and vibrations in the sea.

There is a good deal of obscurity as to the manner in

[1] *Nature*, 9th July 1885.

which vibrations originate. It is obvious that they are caused by the wind and by steamers, but it is not easy to understand how such insignificant causes can produce waves of such great length. But we know that they do so, and certain considerations are adduced in chapter ii. of Darwin's *Tides, &c.*, which show to some extent how the result may be brought about. However this may be, we shall now give some account of another investigation which may perhaps ultimately be found to throw much light on the subject.

Atmospheric waves.

Helmholtz has pointed out (*Preuss. Akad. der Wiss.*, 25th July 1889) that when a layer of one fluid flows over another the surface of separation is necessarily unstable, so that waves will be generated between them. The most familiar instance of this is to be found in the waves generated on the sea by the wind. Another but less obvious case must occur when the air aloft is blowing from a different point of the compass from that near the earth's surface. But it might appear that this should not be considered as an example of the relative motion of two fluids, since the air is all of the same kind. We shall now show, however, that it is proper to regard the atmosphere as consisting of two fluids of different kinds. If the atmosphere were rigorously in that condition which is called adiabatic equilibrium,[1] its temperature and its density would fall at certain definite and uniform rates as we ascend above the earth's surface. But such a uniform rate of fall of temperature and density only represents the average of what would be found to occur in many ascents, and in any individual ascent an abrupt change would occur at the moment of passing from a lower current into an upper one. Hence it follows that, from a mechanical point of view, an upper current should be regarded as consisting of a fluid of a different density from that of the lower current. In this case the instability pointed out by Helmholtz must inevitably follow, and a series of air waves, strictly analogous to those in a rough sea, must be generated. A mackerel sky is the visible proof of the truth of this conclusion, for the moisture is condensed into cloud at the crests of the waves and reabsorbed in the hollows.

Lengths of atmospheric waves determined by comparison with oceanic waves.

It altogether transcends the power of the mathematician to determine what length of wave will be generated by a given wind blowing on a given sheet of water during a given time, but we do know that like circumstances produce like results, so that, for example, a gale in the Atlantic always produces waves of nearly the same length. It is often found that the comparison of similar dynamical systems will lead to interesting conclusions, even when the motion of either system presents a problem intractable by mathematical reasoning. Now, Helmholtz has shown how the waves generated in the surface separating two fluids must be dependent on their relative densities and velocities. He has in this way used the known lengths of sea-waves for obtaining a measure of the lengths of the air-waves aloft. Fairly accurate estimates have been obtained of the effective change of density in passing from the lower to the upper of two currents in the air, and this, together with the relative velocities, affords the data needed for the comparison. In this way he showed that the lengths of the air-waves must be very great, so that in a gale of wind we may expect the waves to have a period of from ten minutes to half an hour; in the latter case the whole visible sky would be occupied by a single crest. This accords exactly with the more or less regular intermission of the furious gusts in a gale, and with the sinuous line marked by the continuous record of a barometer on these occasions.

Vibrations of water probably due to action of atmospheric waves.

Mr Napier Denison has sought to apply this theory to the explanation of some, or many, of the vibrations of lakes and of the sea.[2] He points out that the sea must respond to the alternations of atmospheric pressure, and that the vibrations so generated, when propagated into land-locked bays and harbours, are in fact recorded as zigzags on tide-curves. He has commenced an extensive analysis of the vibrations of the sea in comparison with the oscillations of the barometer. For this purpose he has devised a very sensitive form of barometer which registers the variations of pressure on a large and open scale. The evidence appears favourable to his view, and if his theory shall be ultimately confirmed we shall have obtained an interesting insight into at least one important cause of these vibrations.

At several places Mr Denison believes that the vibrations tend to become manifest at an earlier time than the oscillations of the barometer. If this is so, the water-waves have outrun the advancing atmospheric disturbance, and it thus appears not impossible that the study of vibrations may prove of service in forecasting the weather. The theory is still under trial, and it will need much patient analysis to confirm or refute this interesting speculation.

§ 2. *The Bore in Estuaries.*

In the general description of tidal phenomena in the article on TIDES, it is stated that in estuaries, where large expanses of sand or mud are laid bare at low water, the rising tide sometimes advances in the form of a steep slope of water called a Bore. The rising tide acquires this remarkable shape under the influence of two causes: the first of these is the change of form to which every wave is subject as it progresses in shallow water, the advancing slope becoming steeper and the backward slope less steep. This is exemplified, but in a less exaggerated form, in the figure on p. 362 of TIDES. The second cause is that the natural current of the river holds back the advancing flood until there is a considerable head of water at the mouth of the estuary, and the equilibrium then breaks down suddenly. It does not seem possible to apportion the relative importance of these two causes in the production of the observed effect.

Causes of Bore.

In order to explain more exactly how the latter cause operates, let us consider, in the first place, the tidal currents in a very sluggish river. At any point on the river bank mean water-mark is at such a height that the tide rises above it to the same amount that it falls below it. Then the law governing the tidal currents is simple; it is that whenever the water stands above mean water-mark the current is up-stream, and whenever it stands lower it is down-stream. This result follows at once from the formulæ (54) § 21 of the article TIDES (p. 362). When the water is at mean level it is stagnant, except for the natural current of the river, which we for the moment consider to be so sluggish as to be negligible. At high water the current is most

Tidal currents in estuaries.

[1] In the adiabatic expansion of a gas the pressure varies as the density raised to the power γ, where γ is the ratio of the two specific heats. But pressure also varies jointly as the first powers of the density and of the absolute temperature. Hence the absolute temperature varies as the density raised to the power $\gamma - 1$. From this it easily follows that as we ascend in an atmosphere in adiabatic equilibrium the fall of temperature is proportional to the height of ascent. The law of fall of density is easily deducible from that of the temperature.

[2] *Proc. Canadian Institute*, 16th January and 6th February 1897; *Canadian Engineer*, October and November 1897; *Brit. Assoc. Rep.* (Dover), 1899.

rapid up-stream, and at low water most rapid down-stream. Hence the tidal current "flows" landwards for a long time after high water, and continues to do so, but with diminishing speed, until the water has fallen to mean water-mark. Similarly, the water ebbs seawards from the moment at which the level falls below mean water-mark, with an increasing speed and falling level until low water is reached, and then with a diminishing speed and rising level until mean water is attained.

At a station on the open coast the water flows landwards during the whole of the rise, ebbs seawards during the whole of the fall, and is slack at mean water. The law of tidal currents on the open coast is thus very different from that which holds good in a sluggish river. Now the estuaries of actual rivers broaden and deepen as the sea is approached and a large volume of water is delivered into the sea. Hence the currents in an actual estuary are intermediate between those which would be observed on the open coast and in a river of uniform breadth. It is, of course, to be noted that, whatever may be the state of currents due to the tides, we must superpose on them the proper current of the river. Hence in actual rivers the resultant current continues to flow up-stream after high water is reached, with falling water-level, but ceases flowing before mean water-level is reached, and the resultant current ebbs down-stream after low water, and continues to ebb with the rising tide until mean water is reached, and usually for some time afterwards. The downward stream, in fact, lasts longer than the upward one. The moments at which the currents change will differ in each river according to the depth, the rise and fall of the tide at the mouth of the river, and the amount of water delivered by it into the sea. An obvious consequence of this is that in rivers the tide rises quicker than it falls, and this effect is accentuated by the change of form natural to all waves during their progress in shallow water.

The conditions under which the tide-wave rises and falls in an actual estuary are very complex, and it would hardly be possible to submit them to rigorous mathematical treatment. But this is the less to be regretted, in that the scientific results which might be attained by such treatment would hardly repay us for the great labour inevitable in the attempt. We may then well rest satisfied merely to point out the general principles involved. The bore presents, however, so curious a natural phenomenon as to merit careful observation.

The tide-wave rises as a bore in the Severn, the Wye, the Seine, and the Garonne; perhaps also in other rivers in England and France. But its appearance is capricious, and it is usually conspicuous only at spring-tides and with the wind in certain directions. There is indeed, as far as we know, only one river in which the bore occurs at every tide without exception; that is the Tsientang-kiang, which flows into the China Sea about 60 miles south of the great Yangtse-kiang. Some interesting observations of the bore in the Tsientang were made in 1888 and 1892 by Captain Moore, R.N., when in command of H.M.S. *Rambler*. His survey of the estuary was attended by some danger from the extreme violence of the currents—dangers which experience has taught the navigators of Chinese junks how to avoid. Captain Moore's two reports[1] give many interesting details, and present a graphic description of the bore, together with careful measurements of the rise and fall of the tide in this estuary. It may here suffice to say that the bore is from 12 feet to 15 feet in height, and progresses up the estuary at a speed of about 12 knots. An abstract of these reports is given in Darwin's *Tides, &c.*, chapter iii., together with a reproduction of some previously unpublished photographs which were given to the author by Captain Moore himself.

Bore of the Tsientang-Kiang.

Mr W. Bell Dawson has also made observations at Moncton, on the Petitcodiac river, in the Bay of Fundy, of a bore only slightly less remarkable than the Chinese example. Careful observations of the rise of water at a fixed spot, together with measurements of the rate of progress of the bore up-stream, have enabled Mr Dawson to draw the profile of the tide-wave. The bore itself consists of a precipitous slope of water; and this is succeeded by a more gradual slope, which is, however, interrupted at intervals by several steps or minor bores. An account of Mr Dawson's observations is contained in the "Report of the Tidal Department of the Survey of Canada for 1898," and an abstract of the paper, together with a drawing of one of the profiles, is published in *Nature* of 15th June 1899.

Bore of the Petitcodiac.

§ 3. *Lunar Deflection of Gravity.*

Formulæ were given in § 8 of TIDES (p. 357) for the deflection[2] from the vertical of a pendulum under the lunar attraction, and the section ended with a statement that George and Horace Darwin had made an abortive attempt to measure the lunar deflection of gravity. We shall now give a short account of some more recent investigations bearing on this subject.[3]

It is clear that, if the earth were to yield to the tidal forces to the same degree as a fluid, the movement of the pendulum would be masked from the observer by the simultaneous deflection of the ground on which he stood. Hence a comparison between the observed deflection and that computed on the hypothesis of the absolute rigidity of the earth would afford the means of determining the amount by which the solid earth itself yields to the tidal force. The attainment of such accuracy as to furnish satisfactory numerical results by means of such a comparison is yet distant, but something has already been done in this direction.

Lunar deflection of gravity and rigidity of earth.

When a pendulum is under observation, there is nothing to tell the observer whether it has moved under changes in the direction of gravity relatively to the earth, or of the earth relatively to gravity, or whether both kinds of movement have occurred together. In the experiment referred to above, George and Horace Darwin concluded that almost the whole of the movements were due to motion of the ground. The causes of such a motion are complex; it arises from minute earthquakes, slower earth-movements of obscure origin, the effects of changes of temperature and of the percolation of subterranean water, mixed together in indeterminate proportions. All other observers have noted similar phenomena, and their results are important in the science of seismology, but fall outside the scope of this article.

Amongst many experimenters, there is only one who has been able to adduce any good evidence in favour of the belief that a lunar periodicity can be detected amidst the wandering movements of the pendulum. This is Dr von Rebeur-Paschwitz, whose early death was a great loss to science. Paschwitz made use of a form of instrument called a horizontal pendulum, the nature of which we will now indicate. A door swinging on an absolutely vertical door-

Experiments of Paschwitz.

[1] *The Bore of the Tsientang-kiang*, 1888, and Further Report, &c., 1893. Potter, London.

[2] There was a mistake in that section as to the amount of deflection calculated for the latitude of Cambridge. The angle 0·0216″ there given is the total range, not the semi-range as stated.

[3] For further details see Darwin's *Tides, &c.*, chaps. vi. and vii.

post will rest in any position, but a slight tilt to the door-post imparts to the door a definite position of rest. The mechanical principle of the horizontal pendulum is the same as that of the door; but a horizontal boom replaces the door, and the hinges are steel points resting in agate cups. Observations of the position of rest of the boom and of its period of oscillation determine the direction and magnitude of the inclination to the vertical of the line passing through the points of the two steel pivots. It is easy to see then that movements of the bed of the instrument will be shown by a motion of the boom, and that a continuous record of the motion may be obtained by photography. Two horizontal pendulums in planes at right angles to one another are needed to give a complete record of the motion of the ground.

Paschwitz made prolonged observations in the prime vertical with this form of instrument at Wilhelmshaven, Potsdam, and Orotava, and in the meridian at Strasburg.[1] He almost convinced himself that he could detect a lunar periodicity amidst the wanderings of the pendulum, but a more searching analysis seemed to him to leave the result open to some doubt. After Paschwitz's death his meridional observations were continued at Strasburg by M. Ehlert,[2] who also died young, through a lamentable Alpine accident. The deflections of the pendulum were registered by him during nine months, and the results are in close agreement with those of Paschwitz. Moreover, M. Kortazzi[3] made two series of meridional observations at Nikolaieff, the first lasting sixteen and the second nine months, and found the lunar inequalities to be very clearly marked. It now seems hardly possible to doubt the genuineness of the results of these observers.

We shall now show, however, that even if we assume the lunar periodicity to be a reality, there is still room for doubt as to the extent to which it is due to such a deflection of the vertical as is under consideration in this section.

Flexure of elastic surface by superincumbent load.

A weight resting on a thick horizontal slab must lie in a shallow dimple formed by the elastic yielding of the solid bed. The slope of this dimple must obviously decrease rapidly as we recede from the centre, and mathematical investigation proves that the slope due to pressure at a single point diminishes inversely as the square of the distance from the centre of the depression. The attraction of gravity also obeys the law of the inverse square, and therefore the slope is everywhere proportional to the gravitational attraction. If a number of particles be resting on the slab, each must produce its own dimple and its own attraction, and we conclude that if any weights rest on an elastic horizontal plane, the slopes of the hills and dales into which the originally flat surface is distorted will be everywhere proportional to the attraction; moreover, the direction of steepest slope will be that of the resultant attraction of the weights. The same will be true of weights lying on the earth's surface, because the curvature of the earth will make no material difference in the result.

If the effect of weights imposed on the earth's surface is observed by means of a pendulum, it is clear that the slope of the aggregate of dimples will render itself manifest by a deflection of the pendulum. But we have seen that the gravitational attraction of the weights is proportional to the slope, and therefore attraction must produce a real deflection of the pendulum strictly proportional to the slope of the distorted surface. Thus the total apparent deflection of the pendulum must consist of two parts—one due to slope, and the other to attraction; and there is nothing in the phenomenon itself to tell us how much is produced by one cause and how much by the other. It may, however, be proved by mathematical investigation that the relative importance of the two effects depends on the degree of elasticity of the solid bed. It appears that if the bed has the same elasticity as very stiff glass, the attraction would contribute one-fifth of the whole effect, and if the glass were of the most yielding quality the fraction would be one-eighth. Most rocks are somewhat stiffer than stiff glass, and we shall probably be not far wrong in assuming that with a rock bed of average stiffness the attraction of the load would contribute one-quarter of the total apparent deflection of a pendulum.

Flexure of earth's surface by varying tidal load.

When the tide rises and falls on the sea-coast many millions of tons of water are brought alternately nearer to and farther from the land. There is thus a shifting load which must inevitably affect a pendulum erected on the land, principally through the bending of the rock, but partly also through the direct attraction of the tidal load. The tide oscillates with lunar periodicity in obedience to the tidal forces, and it follows that the lunar periodicity of a pendulum should only be attributed solely to the direct lunar attraction when the observations are made at a great distance from the sea-coast.

Estimate of deflection of pendulum by varying tidal load.

It would be very difficult to compute the changes in the deflections on any actual coast as high and low tides alternate, even if the elasticity of rock were accurately known. It is, however, possible to formulate a problem of ideal simplicity which may serve to give some notion as to the amount of effect to be expected. From the consideration of such an ideal case G. H. Darwin has concluded that at one kilometre from the sea-coast we might expect the total range of oscillation of the pendulum between low and high water to amount to 0·15″; at 10 kilometres the computed range is 0·10″, and at 100 kilometres it is 0·05″.[4] We should note, however, that it is contended by Paschwitz that this ideal problem is not truly representative of actuality. He adduces the irregularity of European coast-lines, and the differences in the time of high water and of the rise of the tide at various places, as reasons for maintaining that G. H. Darwin's numerical estimates are untrustworthy except in close vicinity to the coast. The fact that the results at Nikolaieff present much the same character as those at Strasburg tends to confirm his contention. M. Kortazzi adopts the view of Paschwitz, and thinks that his own observations show the elastic tide of the solid earth to be of such magnitude that the actual deflection of the vertical is reduced to about one-half of the amount as computed for a perfectly rigid earth. Whatever view may ultimately prevail as the general or local character of the deflections of the vertical with lunar periodicity, there is evidence that the weight of the tidal load is responsible for some part of such deflection, at least near the coast. For M. d'Abbadie erected a special form of instrument at his château, about a mile from the Bay of Biscay and close to the Spanish frontier, and observed that the vertical was generally deflected towards the sea at high water and away from it at low water. These normal oscillations were,

Observations of d'Abbadie and of Paschwitz.

however, occasionally interrupted and even reversed, and it seems probable that they were then masked by those slower movements, analogous to earthquakes, which are occupying the attention of seismologists.[1] Paschwitz also at Wilhelmshaven noted similar deflections, which were of surprising magnitude; this may perhaps be explained by the peaty nature of the soil which prevails in that district.

The earth's surface has to bear another variable load besides that of the tide, for every square yard has to support half a ton more when the barometer is very high than when it is very low. Paschwitz, in fact, found that the deflections of the pendulum at Wilhelmshaven showed a connexion with the oscillations of the barometer.

§ 4. *Tide-Tables and the Degree of Accuracy in Tidal Prediction.*

In the article on TIDES, prediction was considered principally from the mathematical point of view,[2] and the practical use of tide-tables and the degree of their success were hardly mentioned. The latter side of the subject will be considered in the present section.

The connexion between the tides and the movements of the moon and sun is so obvious that tidal predictions were regularly made and published long before mathematicians had devoted their attention to them; and these predictions attained considerable success, although they were founded on empirical methods. During the 18th century, and even in the earlier part of the 19th, the art of prediction was regarded as a valuable family secret to be jealously guarded from the public. The best example of this kind of tide-table was afforded by Holden's tables for Liverpool, founded on twenty years of observation by a harbour-master named Hutchinson.[3] In about the year 1832 the researches of Whewell and of Lubbock (senior) pointed the way to improvement on the empirical tables prepared by secret methods, and since that time the preparation of tide-tables has become a branch of science.

Empirical tide-tables.

A perfect tide-table would tell the height of the water at the place of observation at every moment of the day, but such a table would be cumbrous; it is therefore usual to predict only the times and heights of high water and of low water. The best kind of tide-table contains definite forecasts for each day of a definite year, and we may describe it as a special table. Although the table is only made for one definite place, yet it is often possible to give fairly accurate predictions for neighbouring ports by the application of corrections both for time and height. These corrections should not be constant, but should vary according to the positions of the sun and moon. Special tide-tables are published by all civilized countries for their most important harbours.

Prediction for each day.

But there is another kind of table, which we may describe as a general one, where the heights and times are given by reference to the time at which the moon crosses the meridian. Although such a table is only applicable to a definite place, yet it holds good for all time. In this case it is necessary to refer to a nautical almanac for the time of the moon's transit, and a simple calculation then gives the required result. In a general tide-table the heights and times are tabulated according to the hour of the clock at which the moon will cross the meridian at the place of observation. Corrections have to be applied to allow for the effects of the declinations of the moon and sun, and for the lunar parallax. Moreover, at places where there is much diurnal inequality in the tides the moon's visible transit must be treated apart from its transit below the horizon. A considerable degree of elaboration has to be given to the table, in order that it may give accurate results, and it would occupy some half-dozen to a dozen pages of a book, its extension varying according to the degree of accuracy aimed at. It might occupy about five minutes to extract a prediction from the more elaborate form of such a table. There are many ports of considerable commercial importance where, nevertheless, it would hardly be worth while to incur the great and repeated expenditure involved in the publication of special tables. But this kind of elaborate general table has as yet been used in very few cases,[4] and the information furnished to mariners usually consists either of a full prediction for every day of a future year, or of a meagre statement as to the average rise and interval, which must generally be almost useless.

Prediction by reference to time of moon's transit.

The success of tidal predictions varies much according to the place of observation. In stormy regions the errors are often considerable, and the utmost that can be expected of a tide-table is that it shall be correct with a steady barometer and in calm weather. But such conditions are practically non-existent, and therefore errors are inevitable. The former of these sources of error is due to the fact that the sea responds to atmospheric pressure, falling with high pressure and rising with low pressure, at the rate of about a foot of water to an inch of mercury. As regards the second cause, a landward wind usually raises the sea-level; in estuaries the rise is sometimes very great, and even on the open coast it may be considerable. But both these effects seem to be more or less capricious, and it seems only possible to formulate certain rules of probability, the application of which will generally lead to improvement in the prediction as to the height of the water; occasionally, however, such empirical corrections will be found to augment the error.

Meteorological disturbance of prediction.

Notwithstanding these perturbations, tide-tables are usually of surprising accuracy even in northern latitudes; this may be seen from the following table showing the results of comparison between prediction and actuality at Portsmouth. The importance of the errors in height depends, of course, on the range of the tide; it is well, therefore, to note that the average ranges of the tide at springs and neaps are 13 feet 9 inches and 7 feet 9 inches respectively.

Amount of error at Portsmouth.

Prediction at such a place as Portsmouth is difficult, on account of the instability of the weather, but, on the other hand, the tides in themselves are remarkably simple in character. Let us now turn to such a port as Aden, where the weather is very uniform, but the tides very complex on account of the large diurnal inequality, which frequently obliterates one of two successive high waters. The short series of comparisons between actuality and prediction which we give below may be taken as a fair example of what would hold good when a long series is examined. The results refer to the intervals 10th March to 9th April and 12th November to 12th December 1884.

Amount of error at Aden.

[4] Darwin, "Tidal Prediction," quoted above. This kind of table has been applied with some success at Cairns in North Queensland, where there is a large diurnal inequality.

In these two periods there should have been 118 high waters, but the tide-gauge failed to register on one occasion, so that one comparison is lost. We thus have 117 cases to consider, but on one occasion the diurnal inequality obliterated a high water, leaving 116 actual comparisons. The maximum range of the tide at Aden is 8 feet 6 inches, and this serves to give a standard of importance for the errors in height.

Table of Errors in the Prediction of High Water at Portsmouth in the months of January, May, and September 1897.

Time.		Height.	
Magnitude of Error.	Number of Cases.	Magnitude of Error.	Number of Cases.
		Inches	
0^m to 5^m	69	0 to 6	89
6^m to 10^m	50	7 to 12	58
11^m to 15^m	25	13 to 18	24

Errors in Height for the year 1892, *excepting part of July.*

Magnitude of Error.	Number of Cases.
Inches.	
0 to 6	381
7 to 12	228
13 to 18	52
19 to 24	8
31	1
...	670

N.B.—The comparison seems to show that these predictions might be much improved, because the predicted height is nearly always above the observed height, and because the diurnal inequality has not been taken into account sufficiently, if at all.

Table of Errors of the Prediction of High Water at Aden in March–April and November–December 1884.

Time.		Height.	
Magnitude of Error.	Number of Cases.	Magnitude of Error.	Number of Cases.
		Inches	
0^m to 5^m	35	0	15

56^m and 57^m	2	...	...
No high water.	1	...	...
.	117	..	117

It would be natural to think that when a prediction is erroneous by as much as fifty-seven minutes it is a very bad one, but we shall show that such a conclusion may be unjust. There was one case in which the high water was completely obliterated by the diurnal inequality, but there were many others in which there was nearly complete obliteration, so that the water stood nearly stagnant for several hours. A measure of the degree of stagnation is afforded by the amount of rise from low to high water. Now, on examining all the eleven cases where the error of time was equal to or over twenty minutes, we find five cases in which the range from low to high water was less than 8 inches, and these include the errors of fifty-six and of fifty-seven minutes. There is one case of a rise of 13 inches with an error of thirty-six minutes; one case of a rise of 17 inches with an error of twenty-two minutes; one of 19 inches rise with thirty-three minutes error. The remaining three cases have rises of 2 feet 10 inches, 3 feet 9 inches, 3 feet 11 inches, and errors of twenty-two, twenty-three, twenty minutes. Thus all the very large errors of time correspond with approximate stagnation, and are quite unimportant. It is fair to conclude, therefore, that the predictions as to time are very good. The predictions as to height are obviously good, for more than half were within 1 inch, and only eleven had an error of as much as 4 inches.

When it is considered that the incessant variability of the tidal forces, the complex outlines of the coast, the depth of the sea, the earth's rotation, and the perturbations by meteorological influences are all involved, it should be admitted that the success of tidal prediction is very remarkable. If further evidence were needed, we might appeal to tidal prediction as a convincing proof of the truth of the theory of gravitation.

Dynamical Theory of Tides.

§ 5. *Oversight in the Article on "Tides" (vol. xxiii. p.* 358).

The dynamical equations for tidal oscillations are established in § 11 of the article Tides, but in the endeavour to obtain succinctness one of the steps in the proof was given without sufficient explanation.

The equations (16) purport to give the accelerations in the radial, colatitudinal, and longitudinal directions. They should have been written as follows :—

$$R=\frac{d^2\rho}{dt^2}-2n\sin^2\theta\,\frac{d\eta}{dt}-n^2r\sin^2\theta,$$

$$\Xi=\frac{d^2\xi}{dt^2}-2n\sin\theta\cos\theta\,\frac{d\eta}{dt}-n^2r\sin\theta\cos\theta,$$

$$H=\sin\theta\,\frac{d^2\eta}{dt^2}+2n\cos\theta\,\frac{d\xi}{dt}.$$

The oversight referred to consists in the omission of the last term in Ξ. It is true that this term does disappear, as will be shown below, but it should not have been omitted without further explanation. ***Equations of motion.***

If Ω denotes the potential of the external forces under which the particle whose accelerations are R, Ξ, H moves, but inclusive of the potential corresponding to a uniform angular velocity n, it is clear that the actual potential is $\Omega-\frac{1}{2}n^2r^2\sin^2\theta$. Then the differentials $\frac{d}{dr}$, $\frac{d}{rd\theta}$, $\frac{d}{r\sin\theta d\phi}$ of the last-named function must be equal to R, Ξ, H respectively, and it becomes obvious that $n^2r\sin^2\theta$ and $n^2r\sin\theta\cos\theta$ will disappear from the first and second equations.

Now Ω is the potential of the forces when the system has been rendered statical by the addition of a rotation potential, and the arguments adduced in the article show that $\Omega=-g\,(\mathfrak{y}-\mathfrak{x})\,r^2/a^2$. Also the radial motion, being excessively small compared with the horizontal motion, need not be considered; thus the equations of motion have the form shown in (17) of the article in the ninth edition of this work.

As we are referring to errors in the article in the ninth edition, it may be well to note that there is a misprint on p. 368, § 30, in the formula for 2μ; for H_m should occur in the denominator in all the terms on the right excepting the first.

§ 6. *Recent Advances in the Dynamical Theory of the Tides.*

In two papers contained in the second volume of Liouville's *Journal* (1896) M. Poincaré has considered the mathematical principles involved in the tidal problem where the ocean is interrupted by land, as in actuality. He has not sought to obtain numerical results applicable to any given configuration of land and sea, but he has rather aimed at pointing out the methods by which it may be some day possible to obtain such solutions. It would hardly be in place to attempt in this article to follow the details of an investigation of this character; but we may say that it affords a conspicuous example of M. Poincaré's power of reaching the

very heart of a difficult problem, and exhibits his consummate skill in the treatment of mathematical analysis.

We shall, however, notice in some detail two other still more recent papers[1] by Mr S. S. Hough, in which he has carried the solution of our problem considerably farther than the point at which it was left by Laplace.

In the article on TIDES we were compelled to follow Laplace in treating the ocean as deprived of the power of attracting itself, but Mr Hough has been able, by the use of spherical harmonic analysis, to include in his results the effects of the mutual gravitation of the water. The physical results are not profoundly affected by this addition, and so far the principal interest lies in the improvement of the mathematical method. But the author has also made a far more fundamental advance. In the tides, as in all other dynamical problems, the determination of the oscillations which the system is capable of executing when free from the action of external causes affords the only clue whereby it is possible to discuss completely the oscillations executed under external forces. Now oceanic tides are "forced oscillations" due to the moon and sun, and although Laplace showed how such tides were determinable on an ocean-covered planet, he failed to give a complete analysis of the various modes of "free oscillation." Mr Hough has now succeeded, by very skilful analysis, in finding a complete solution of the problem, and he has thus placed the theory on a far more satisfactory basis than that on which it stood before.

We shall in the following sections give Mr Hough's investigation in outline, but shall confine our attention more to "free" than to "forced" oscillations.

§ 7. *Equation of Tidal Oscillation.*

This would not be an appropriate place in which to follow the author in his careful discussion of the nature of the approximations by which the problem is treated. It may suffice to say that he confirms Laplace's results, which were reproduced in § 11 of the article on TIDES. It is only necessary to point out how the effects of the mutual gravitation of the ocean may be included in the equation.

We denoted the height of the dynamical tide by $\mathfrak{y}$, and that of the equilibrium tide by $\mathfrak{x}$. These two quantities are of course functions of the co-latitude θ and of the longitude ϕ, and may obviously be expanded in spherical harmonics, so that we may write

$$\mathfrak{y}=\Sigma\,\mathfrak{y}_i, \quad \mathfrak{x}=\Sigma\,\mathfrak{x}_i,$$

where each term in the series is a spherical harmonic of θ, ϕ of the order indicated by the suffix.

Mutual attraction of water. It is easy to prove, by a process exactly similar to that pursued in § 6 of the article on TIDES, that if the equation to the surface of the ocean be $r=a+\mathfrak{y}_i$ or $\mathfrak{x}_i$, it is in equilibrium under the action of external forces of which the potential is

$$g\frac{r^i}{a^i}\left(1-\frac{3\sigma}{(2i+1)\,\delta}\right)(\mathfrak{y}_i \text{ or } \mathfrak{x}_i).$$

In this formula g is gravity, σ the density of water, δ the mean density of the earth, and r is the radius vector.

Let us write for brevity

$$b_i=1-\frac{3\sigma}{(2i+1)\,\delta}, \quad . \quad . \quad . \quad . \quad (1)$$

where the subscript i is not to be taken as denoting a spherical harmonic. In the article on TIDES we assumed b_i to be unity because we virtually took σ/δ as zero. It was shown in that article that the whole of the forces due to fluid pressure and to external attractions might be included by supposing that an element of the ocean moved under the influence of a potential $-g(\mathfrak{y}-\mathfrak{x})\,r^2/a^2$. But it is now obvious that when the attraction of the water is included this potential will become $-\Sigma b_i g(\mathfrak{y}_i-\mathfrak{x}_i)r^2/a^2$. Accordingly, the right-hand side of the two equations (18) should be $-\Sigma b_i\frac{g}{a}\frac{d}{d\theta}(\mathfrak{y}_i-\mathfrak{x}_i)$ and $-\frac{\Sigma b_i g}{a\sin\theta}\frac{d}{d\phi}(\mathfrak{y}_i-\mathfrak{x}_i)$ respectively. The equation of continuity (19) remains unchanged.

The next step was to assume that $\mathfrak{x}$, $\mathfrak{y}$, ξ were proportional to $\cos(2nft+k\phi+\alpha)$, and that η was proportional to $\sin(2nft+k\phi+\alpha)$. We should assume, for example,

$$\mathfrak{x}=\Sigma\mathfrak{x}_i=\Sigma e_i\cos(2nft+k\phi+\alpha).$$

Here $\mathfrak{x}_i$ is a spherical harmonic of order i, and e_i is the "associated function" of co-latitude such that $e_i\begin{matrix}\cos\\ \sin\end{matrix}k\phi$ is a harmonic of order i. It is obvious that k is the rank of the tesseral harmonic in which e_i is the associated function. As it has been usual to denote the rank of a tesseral harmonic by the letter s, we shall now replace k by s.

[1] *Phil. Trans. Roy. Soc.*, vol. 189 A. (1897), pp. 201–258, and vol. 191 A. (1898), pp. 139–185.

The next step was the determination of x, y (which replace ξ,η) from the equations of motion; and it is clear that in the new solution x, y should be replaced by $\Sigma b_i x_i$, $\Sigma b_i y_i$. The substitution in the equation of continuity gave the equation (24), which we may now write ***Differential equation of tidal oscillation.***

$$\frac{1}{\sin\theta}\frac{d}{d\theta}\left[\frac{\gamma(\sin\theta\frac{d}{d\theta}+\frac{s}{f}\cos\theta)(h-e)}{f^2-\cos^2\theta}\right]-\frac{s\gamma\left(\frac{\cos\theta}{f}\frac{d}{d\theta}+\frac{s}{\sin\theta}\right)(h-e)}{\sin\theta(f^2-\cos^2\theta)}+4mah=0 \quad . \quad . \quad (2)$$

The only effect of the introduction of mutual gravitation will be that in the first two terms $(h-e)$ should be replaced by $\Sigma b_i(h_i-e_i)$. We may then continue to use the equation in the above form, if we bear in mind that the factors b_i are to be introduced at the stage where the spherical harmonics are first used.

It will be well to remind the reader of the meaning of the several symbols.

The ratio of centrifugal force at a distance equal to the earth's radius a to gravity g is denoted by m, so that $m=n^2a/g$.

The depth of the ocean, covering the whole planet, is γ; and, as we shall only consider the case of an ocean of uniform depth, γ is a constant. The "speed of the tide" is $2nf$, so that $2f$ is the frequency of the tide in the sidereal day. The rank of the tesseral harmonic is denoted by s. Lastly, h and e are the semi-amplitudes of the actual and of the equilibrium tides; they are functions of co-latitude θ.

§ 8. *Zonal Oscillations.*

We might treat the general harmonic oscillations first, and proceed to the zonal oscillations by putting $s=0$. These waves are, however, comparatively simple, and it is well to begin with them. The zonal tides are those which Laplace describes as of the first species, and are now more usually called the tides of long period; they were treated in § 17 of the article on TIDES. ***Zonal oscillations.***

In this case $s=0$, and our equation (2) becomes

$$\frac{d}{d\theta}\left(\frac{\sin\theta\frac{d}{d\theta}(h-e)}{f^2-\cos^2\theta}\right)+\frac{4ma}{\gamma}h\sin\theta=0.$$

This may be written

$$\frac{d}{d\theta}(h-e)+\frac{4ma}{\gamma}\frac{f^2-\cos^2\theta}{\sin\theta}\int^\theta h\sin\theta d\theta+A=0, \quad . \quad . \quad (3)$$

where A is a constant. It must be remembered further that when the first term is expanded in spherical harmonics the term h_i-e_i must be multiplied by the factor b_i.

Let us assume

$$h=\Sigma C_i P_i, \quad \mathfrak{x}=\Sigma E_i P_i$$

where P_i denotes the ith zonal harmonic of $\cos\theta$. The coefficients C_i are unknown, but the E_i are known because the system oscillates under the action of known forces.

If the term involving the integral in this equation were expressed in terms of differentials of harmonics, we should be able to equate to zero the coefficient of each $dP_i/d\theta$ in the equation, and thus find the conditions for determining the C's.

The task then is to express $\frac{f^2-\cos^2\theta}{\sin\theta}\int^\theta P_i\sin\theta d\theta$ in differentials of zonal harmonics.

It is well known that P_i satisfies the differential equation

$$\frac{d}{d\theta}\left(\sin\theta\frac{dP_i}{d\theta}\right)+i(i+1)P_i\sin\theta=0. \quad . \quad . \quad (4)$$

Therefore $\int P_i\sin\theta d\theta=-\frac{1}{i(i+1)}\sin\theta\frac{dP_i}{d\theta}$, and

$$\frac{f^2-\cos^2\theta}{\sin\theta}\int P_i\sin\theta d\theta=-\frac{1}{i(i+1)}(f^2-\cos^2\theta)\frac{dP_i}{d\theta}$$
$$=-\frac{1}{i(i+1)}(f^2-1)\frac{dP_i}{d\theta}-\frac{1}{i(i+1)}\sin^2\theta\frac{dP_i}{d\theta}.$$

Another well-known property of zonal harmonics is that

$$\sin\theta\frac{dP_i}{d\theta}=\frac{i(i+1)}{2i+1}(P_{i+1}-P_{i-1}) \quad . \quad . \quad . \quad (5)$$

If we differentiate (5) and use (4) we have

$$\frac{i(i+1)}{2i+1}\left(\frac{dP_{i+1}}{d\theta}-\frac{dP_{i-1}}{d\theta}\right)+i(i+1)P_i\sin\theta=0 \quad . \quad (6)$$

Multiplying (5) by $\sin\theta$, and using (6) twice over

$$\sin^2\theta\frac{dP_i}{d\theta}=\frac{i(i+1)}{2i+1}\left\{-\frac{1}{2i+3}\left(\frac{dP_{i+2}}{d\theta}-\frac{dP_i}{d\theta}\right)+\frac{1}{2i-1}\left(\frac{dP_i}{d\theta}-\frac{dP_{i-2}}{d\theta}\right)\right\}.$$

Therefore $$\frac{f^2-\cos^2\theta}{\sin\theta}\int P_i \sin\theta d\theta = \frac{1}{(2i-1)(2i+1)}\frac{dP_{i-2}}{d\theta} - \left\{\frac{f^2-1}{i(i+1)}+\frac{2}{(2i-1)(2i+3)}\right\}\frac{dP_i}{d\theta}+\frac{1}{(2i+1)(2i+3)}\frac{dP_{i+2}}{d\theta}.$$

This expression, when multiplied by $4ma/\gamma$ and by C_i and summed, is the second term of our equation.

The first term, with the introduction of the factors b_i, is

$$\Sigma b_i(C_i-E_i)\frac{dP_i}{d\theta}.$$

In order that the equation may be satisfied, the coefficient of each $dP_i/d\theta$ must vanish identically. Accordingly we multiply the whole by $\gamma/4ma$ and equate to zero the coefficient in question, and obtain

$$\frac{b_i\gamma}{4ma}(C_i-E_i)+\frac{C_{i-2}}{(2i-1)(2i-3)}-\left\{\frac{f^2-1}{i(i+1)}+\frac{2}{(2i-1)(2i+3)}\right\}C_i + \frac{C_{i+2}}{(2i+3)(2i+5)}=0 \quad . \quad (7)$$

This equation (7) is applicable for all values of i from 1 to infinity, provided that we take C_0, E_0, C_{-1}, E_{-1} as being zero.

The equation amongst the C's presents a close analogy with (45) of § 18 of the article on TIDES, and is treated in a similar manner. We shall not, however, pursue the investigation of the tides of long period, merely stating that Mr Hough's results are confirmatory of those obtained in § 18 of the article on TIDES.

Free zonal oscillations. The free oscillations of the ocean of the zonal type may be treated by means of this equation, and since in this case there is no disturbing force, all the E's vanish.

If we write for brevity

$$L_i=\frac{f^2-1}{i(i+1)}+\frac{2}{(2i-1)(2i+3)}-\frac{b_i\gamma}{4ma},$$

the equation (7) is

$$\frac{C_{i+2}}{(2i+3)(2i+5)}-L_iC_i+\frac{C_{i-2}}{(2i-3)(2i-1)}=0 \quad . \quad . \quad (8)$$

The problem is to eliminate the C's from an infinite series of these equations and to determine f the semi-frequency of oscillation. Since the dimensions and mean density of the earth, the density of sea-water, and the depth of the ocean are known, the last term in L_i is known.

With respect to this result Mr Hough writes :—"The equations divide themselves into two groups, in one of which only even suffixes, and in the others of which only odd suffixes, are involved. We conclude, therefore, that the types of oscillation divide themselves into two classes, in the former of which the height of the surface waves will be expressible entirely by harmonics of even order, and in the latter by harmonics of odd order alone. An exactly similar treatment is applicable to each of these classes; we shall therefore select for discussion the former set."

Remembering that C_0 is to be regarded as zero, the first three equations of the even set are

$$C_2L_2+\frac{C_4}{7.9}=0,$$

$$\frac{C_2}{5.7}-C_4L_4+\frac{C_6}{11.13}=0,$$

$$\frac{C_4}{7.9}-C_6L_6+\frac{C_8}{15.17}=0.$$

It would seem at first sight that these equations would serve to determine C_4, C_6, C_8... in terms of C_2, but the same difficulties arise as were found to occur in § 16 of the article on TIDES. and they are to be met in a similar manner.

If we write for brevity

$$a_i=\frac{1}{(2i+1)(2i+3)^2(2i+5)},$$

the equation amongst the C's may be written in the alternative forms

$$\frac{C_{i-2}/C_i}{(2i-3)(2i-1)}=L_i-\frac{a_i}{C_i/C_{i+2}},$$

$$\frac{C_{i+2}/C_i}{(2i+3)(2i+5)}=L_i-\frac{a_{i-2}}{C_i/C_{i-2}}.$$

By successive applications of these formulæ the right-hand side may, in each case, be expressed as a continued fraction.

Let us express the following continued fractions by a single symbol, and write

$$H_{i-2}=\frac{a_i}{L_{i+2}-}\,\frac{a_{i+2}}{L_{i+4}-}\,\frac{a_{i+4}}{L_{i+6}-}\ldots,$$

$$K_{i+2}=\frac{a_{i-2}}{L_{i-2}-}\,\frac{a_{i-4}}{L_{i-4}-}\,\frac{a_{i-6}}{L_{i-6}-}\ldots.$$

Then

$$\left.\begin{aligned}\frac{C_{i-2}/C_i}{(2i-3)(2i-1)}&=L_i-H_{i-2}\\ \frac{C_{i+2}/C_i}{(2i+3)(2i+5)}&=L_i-K_{i+2}\end{aligned}\right\} \quad . \quad . \quad . \quad (9)$$

Frequency equation. By substitution in the equation (8) we have as the general condition

$$L_i-H_{i-2}-K_{i+2}=0.$$

The C's have disappeared, and we are left with an equation for determining f, the frequency of oscillation.

The equation may be written in many other forms, but the object attained by this particular form is that a selected portion, namely, L_i, stands out by itself.

The values 2, 4, 6, &c., are to be attributed successively to i, and the equation solved in the manner indicated below. When the similar series of equations corresponding to the odd harmonics are solved, we shall have a systematic solution of the whole, containing all the possible modes of oscillation.

Reverting, however, to the even series, the solution is effected as follows :—

Solution. We first compute the numerical portion of all the L's, and obtain a series of equations such as

$$L_i=\frac{1}{i(i+1)}(f^2-A_i),$$

where A_i is a number.

As a first approximation we assume that one particular L, say L_i, vanishes; then $f=\sqrt{A_i}$. With this value of f we compute L_2, L_4, L_6... up to a pretty high order, and one of the series, namely L_i, will be zero.

The continued fractions H_{i-2}, K_{i+2} are then computed. They are so rapidly convergent that a few terms suffice to give them with all necessary accuracy. If B be the value of $H_{i-2}+K_{i+2}$, we shall have the function $L_i-H_{i-2}-K_{i+2}$ equal to $-B$, when f is equal to $\sqrt{A_i}$.

We next assume that $L_i=B$, so that $f=\sqrt{(A_i+i(i+1)B)}$, and go through the same process as before, finding $L_i-H_{i-2}-K_{i+2}$ equal, say, to $+C$.

By interpolation it is easy to find the exact value of f, which causes $L_i-H_{i-2}-K_{i+2}$ to vanish. If $-B$ and C are found to differ too widely from one another it is, of course, easy to repeat the process of approximation.

In this way Mr Hough has found the frequencies of all the modes of oscillations expressible by the harmonics of orders 1 to 12, for depths of ocean equal to once, twice, four times, and eight times 7260 feet.

In the case of a non-rotating planet each harmonic forms a fundamental mode of oscillation capable of existing by itself, but this is not the case for a rotating planet. The next task is then to determine the nature of the waves which correspond to each of the frequencies; this entails the determination of the C's.

Since $L_i-H_{i-2}=K_{i+2}$ and $L_i-K_{i+2}=H_{i-2}$ the equations (9) give us

Form of waves.

$$\frac{C_{i-2}}{C_i}=(2i-1)(2i-3)K_{i+2},$$

$$\frac{C_{i+2}}{C_i}=(2i+3)(2i+5)H_{i-2}.$$

In the course of finding the frequency the H, K continued fractions have been determined, and therefore we can find C_{i-2} and C_{i+2} in terms of C_i.

By putting $i-2$ for i in the first formula and $i+2$ for i in the second, we can find C_{i-4} in terms of C_{i-2}, and thence of C_i; also C_{i+4} in terms of C_{i+2} and thence of C_i. By continuing this process all the C's are determinable as multiples of C_i, which is the arbitrary constant of the solution

$$\mathfrak{y}=C_i\left\{\ldots+\frac{C_{i-2}}{C_i}P_{i-2}+P_i+\frac{C_{i+2}}{C_i}P_{i+2}+\ldots\right\}\cos(2nft+\alpha).$$

It appears that when i is considerable the coefficients of the P's on each side of P_i are not very large, so that the ith harmonic stands out from the rest. If the planet did not rotate the corresponding solution would be $C_iP_i\cos(2nft+\alpha)$, and $2nf$ would not differ much in the two cases. But this is by no means the case for small values of i; for example, when $i=1$ and the depth of ocean 7260 feet, the solution is

$$\mathfrak{y}=C_1\{P_1-1{\cdot}5058P_3+{\cdot}7106P_5-{\cdot}1673P_7\ldots\}\cos(2nft+\alpha),$$

and the period π/nf is $30^{\text{h}}\ 29^{\text{m}}$.

But for the non-rotating globe the corresponding solution is $\mathfrak{y}=C_1P_1\cos(2nft+\alpha)$, with π/nf equal to $59^{\text{h}}\ 17^{\text{m}}$.

In the rotating planet the third harmonic has a greater coefficient than the first, and the fifth has nearly as much importance. This perhaps tends to explain the great discrepancy between the periods of oscillation in the two cases.

We refer the reader to Mr Hough's first paper (*Phil. Trans.* A.

1897, pp. 201–257) for a valuable series of numerical results illustrative of the theory.

Steady currents of ocean. In the latter part of his paper Mr Hough shows that there are other solutions of the differential equations which do not correspond to oscillations, but to steady motions.

The differential equations of motion and the equation of continuity are given in (17) and (18) of § 11 of the article on TIDES. If there be no disturbing force they are as follows :—

$$\frac{d^2\xi}{dt^2} - 2n\sin\theta\cos\theta\frac{d\eta}{dt} = -\frac{g}{a}\frac{d\mathfrak{h}}{d\theta},$$

$$\sin\theta\frac{d^2\eta}{dt^2} + 2n\cos\theta\frac{d\xi}{dt} = -\frac{g}{a\sin\theta}\frac{d\mathfrak{h}}{d\phi},$$

$$a\frac{d\mathfrak{h}}{dt} + \frac{d}{d\theta}\left(\gamma\sin\theta\frac{d\xi}{dt}\right) + \frac{d}{d\phi}\left(\gamma\sin\theta\frac{d\eta}{dt}\right) = 0.$$

In the previous solutions we have supposed γ to be a function of co-latitude only, and indeed, where the solution has been considered in detail, to be constant. This restriction will now be removed. Let us suppose, if possible, that there is a condition of steady motion which will satisfy these equations. Then the velocities and the elevation of the surface are not functions of the time, so that the equations reduce to

$$\left.\begin{aligned}\sin\theta\frac{d\eta}{dt} &= \frac{g}{2an\cos\theta}\frac{d\mathfrak{h}}{d\theta}\\ \frac{d\xi}{dt} &= -\frac{g}{2an\cos\theta}\frac{d\mathfrak{h}}{\sin\theta d\phi}\end{aligned}\right\} \quad . \quad . \quad . \quad (10)$$

Therefore the equation of continuity becomes

$$\frac{d}{d\theta}\left(\frac{\gamma}{\cos\theta}\frac{d\mathfrak{h}}{d\phi}\right) = \frac{d}{d\phi}\left(\frac{\gamma}{\cos\theta}\frac{d\mathfrak{h}}{d\theta}\right) \quad . \quad . \quad . \quad (11)$$

The equation of continuity is satisfied if $\mathfrak{h}$ and γ are functions of co-latitude only, and the first of the equations of motion then shows what velocity must be imparted to the fluid in order to give the figure of the ocean any arbitrary form, provided it is a figure of revolution. The distribution must, however, be symmetrical with respect to the equator, for if $\mathfrak{h}$ were to involve any odd harmonic the necessary velocity would be infinite at the equator.

Reverting, however, to the general case, where the depth of the ocean may vary in longitude as well as in latitude, it is clear that if, starting from any point, we pursue a line along which $\mathfrak{h}$ is constant, we must have

$$\frac{d\mathfrak{h}}{d\theta}\delta\theta + \frac{d\mathfrak{h}}{d\phi}\delta\phi = 0.$$

Therefore

$$\left(\sin\theta\frac{d\eta}{dt}\right)\delta\theta - \frac{d\xi}{dt}(\sin\theta\delta\phi) = 0.$$

But $\sin\theta d\eta/dt$ is the eastward velocity, and $d\xi/dt$ is the southward velocity, so that the displacements $\delta\theta$, $\delta\phi$ indicate motion with the fluid. Hence $\mathfrak{h}$ is constant along a stream line, or $\mathfrak{h}$ is a stream function. In this statement we have omitted the attraction of the water on itself, but from what has gone before it is obvious that when the attraction is included the stream function is $\Sigma b_i\mathfrak{h}_i$. In the same way in (11) $\mathfrak{h}$ must be replaced by $\Sigma b_i\mathfrak{h}_i$, and it follows from this equation that $\gamma/\cos\theta$ is constant along a stream line. Therefore the stream lines are determined by the consideration that the depth of the ocean multiplied by the secant of the co-latitude is constant. It would thus be possible to draw the stream lines for these oceanic currents on an actual chart. However, the fact that the ocean consists of fluid of slightly different densities in different places would introduce effects resulting in a total subversion of the theoretical arrangements of currents. The driving forces which overcome friction must be sought in precipitation, evaporation, and the wind, and the whole circumstances of the actual problem are so complex that mathematical treatment becomes almost impossible. The reader is referred to Mr Hough's paper for further consideration of the subject.

Stream lines of ocean currents.

§ 9. *Tesseral Oscillations.*

Tesseral oscillations. Transformation of equation. The oscillations which we now have to consider are those in which the form of surface is expressible by the tesseral harmonics. The results will be applicable to the diurnal and semidiurnal tides—Laplace's second and third species.

If we write $\sigma = \frac{s}{i}$ the equation becomes

$$\frac{d}{d\theta}\left[\frac{\left(\sin\theta\frac{d}{d\theta} + \sigma\cos\theta\right)(h-e)}{s^2-\sigma^2\cos^2\theta}\right] - \frac{\left(\sigma\cos\theta\frac{d}{d\theta} + s^2\ \operatorname{cosec}\theta\right)(h-e)}{s^2-\sigma^2\cos^2\theta} + \frac{4ma}{\gamma\sigma^2}h\sin\theta = 0.$$

It must be borne in mind that when h and e are expressed in harmonics, $h-e$, as it occurs in the first two terms, must be replaced by $\Sigma b_i(h_i-e_i)$, where h_i, e_i are the associated functions of the co-latitude, such that h_i or c_i multiplied by $\cos s\phi$ or $\sin s\phi$ are tesseral harmonics. If we write D for the operation $\sin\theta\frac{d}{d\theta}$, the middle term may be arranged in the form

$$-\frac{\sigma\cot\theta\,(D+\sigma\cos\theta)(h-e)}{s^2-\sigma^2\cos^2\theta} - \frac{h-e}{\sin\theta}.$$

Therefore on multiplying by $\sin\theta$ the equation becomes

$$(D-\sigma\cos\theta)\left[\frac{(D+\sigma\cos\theta)(h-e)}{s^2-\sigma^2\cos^2\theta}\right] - (h-e) + \frac{4ma}{\gamma\sigma^2}h\sin^2\theta = 0 \quad (12)$$

All the terms except the last will need multiplication by b_i when the attraction of the water is included.

We now introduce two auxiliary functions, such that

$$\left.\begin{aligned}h-e &= \Sigma b_i\,(h_i-e_i),\\ &= (D-\sigma\cos\theta)\,\Psi + (s^2-\sigma^2\cos^2\theta)\,\Phi \quad . \quad .\end{aligned}\right. \quad (13)$$

It is easy to prove that

$$\left.\begin{aligned}(D+\sigma\cos\theta)(D-\sigma\cos\theta) &= D^2-s^2+\sigma\sin^2\theta+(s^2-\sigma^2\cos^2\theta),\\ (D-\sigma\cos\theta)(D+\sigma\cos\theta) &= D^2-s^2-\sigma\sin^2\theta+(s^2-\sigma^2\cos^2\theta).\end{aligned}\right\} \quad (14)$$

Also

$$(D+\sigma\cos\theta)(s^2-\sigma^2\cos^2\theta)\,\Phi = (s^2-\sigma^2\cos^2\theta)(D+\sigma\cos\theta)\,\Phi + 2\sigma^2\sin^2\theta\cos\theta\,\Phi \quad . \quad (15)$$

Now perform $D+\sigma\cos\theta$ on (13), and use the first of (14) and (15), and we have

$$(D+\sigma\cos\theta)(h-e) = (D^2-s^2+\sigma\sin^2\theta+s^2-\sigma^2\cos^2\theta)\Psi + (s^2-\sigma^2\cos^2\theta)(D+\sigma\cos\theta)\Phi + 2\sigma^2\sin^2\theta\cos\theta\,\Phi \quad (16)$$

The functions Ψ and Φ are as yet indeterminate, and we may impose another condition on them. Let that condition be

$$\frac{1}{\sin^2\theta}(D^2-s^2+\sigma\sin^2\theta)\Psi = -2\sigma^2\cos\theta\,\Phi \quad . \quad . \quad (17)$$

Then (16) may be written

$$\frac{(D+\sigma\cos\theta)(h-e)}{s^2-\sigma^2\cos^2\theta} = \Psi + (D+\sigma\cos\theta)\Phi.$$

Substituting from this in (12), and using the second of (14), the function Ψ disappears and the equation reduces to

$$(D^2-s^2-\sigma\sin^2\theta)\Phi + \frac{4ma}{\gamma\sigma^2}h\sin^2\theta = 0 \quad . \quad . \quad (18)$$

Since by (17) $-\sigma^2\cos^2\theta\,\Phi = \frac{1}{2}\frac{\cos\theta}{\sin^2\theta}(D^2-s^2+\sigma\sin^2\theta)\Psi$, (13) may be written

$$\Sigma b_i(h_i-e_i) = \left[D-\sigma\cos\theta+\tfrac{1}{2}\frac{\cos\theta}{\sin^2\theta}(D^2-s^2+\sigma\sin^2\theta)\right]\Psi + s^2\Phi \quad (19)$$

The equations (17), (18), and (19) define Ψ and Φ, and furnish the equation which must be satisfied.

If we denote $\cos\theta$ by μ the zonal harmonics are defined by

$$P_i = \frac{1}{2^i i!}\left(\frac{d}{d\mu}\right)^i(\mu^2-1)^i.$$

The following are three well-known properties of zonal harmonics—

$$\frac{d}{d\mu}\left[(1-\mu^2)\frac{dP_i}{d\mu}\right] + i(i+1)P_i = 0, \quad . \quad . \quad (20)$$

$$(i+1)P_{i+1} - (2i+1)\mu P_i + iP_{i-1} = 0, \quad . \quad . \quad (21)$$

$$\frac{dP_{i+1}}{d\mu} - \frac{dP_{i-1}}{d\mu} = (2i+1)P_i. \quad . \quad . \quad . \quad (22)$$

If $P_i^s\begin{matrix}\cos\\ \sin\end{matrix}s\phi$ are the two tesseral harmonics of order i and rank s, it is also known that

$$P_i^s = (1-\mu^2)^{\frac{1}{2}s}\frac{d^sP_i}{d\mu^s} \quad . \quad . \quad . \quad . \quad (23)$$

Let us now assume

$$h = \Sigma C_i^sP_i^s, \quad e = \Sigma E_i^sP_i^s, \quad \Psi = \Sigma\alpha_i^sP_i^s, \quad \Phi = \Sigma\beta_i^sP_i^s.$$

These must now be substituted in our three equations (17), (18), (19), and the result must be expressed by series of the P_i^s functions. It is clear then that we have to transform into P_i^s functions the following functions of P_i^s, namely

$$\frac{1}{\sin^2\theta}(D^2-s^2\pm\sigma\sin^2\theta)P_i^s, \quad \cos\theta P_i^s,$$

$$\left[D-\sigma\cos\theta+\tfrac{1}{2}\frac{\cos\theta}{\sin^2\theta}(D^2-s^2+\sigma\sin^2\theta)\right]P_i^s.$$

If we differentiate (20) s times, and express the result by means of the operator D, we find

$$(D^2-s^2)P_i^s + i(i+1)P_i^s\sin^2\theta = 0 \quad . \quad . \quad . \quad (24)$$

Again, differentiating (21) s times and using (22), we find

$$(i-s+1)P_{i+1}^s-(2i+1)\cos\theta P_i^s+(i+s)P_{i-1}^s=0 \quad . \quad (25)$$

Lastly, differentiating (23) once and using (20), (22), and (25)

$$DP_i^s=\frac{i(i-s+1)}{2i+1}P_{i+1}^s-\frac{(i+1)(i+s)}{2i+1}P_{i-1}^s \quad . \quad . \quad (26)$$

By means of (24), (25), and (26) we have

$$\frac{1}{\sin^2\theta}(D^2-s^2\pm\sigma\sin^2\theta)P_i^s=[-i(i+1)\pm\sigma]P_i^s,$$

$$\cos\theta\,P_i^s=\frac{i+s}{2i+1}P_{i-1}^s+\frac{i-s+1}{2i+1}P_{i+1}^s,$$

$$\left[D-\sigma+\tfrac{1}{2}\frac{\cos\theta}{\sin^2\theta}(D^2-s^2+\sigma\sin^2\theta)\right]P_i^s=-\frac{(i-s+1)[\sigma+i(i-1)]}{2(2i+1)}P_{i+1}^s$$
$$-\frac{(i+s)[\sigma+(i+1)(i+2)]}{2(2i+1)}P_{i-1}^s.$$

Therefore the equations (17), (18), (19) give

$$\Sigma\left[\alpha_i^s\left\{-i(i+1)+\sigma\right\}P_i^s+2\sigma^2\beta_i^s\left\{\frac{i+s}{2i+1}P_{i-1}^s+\frac{i-s+1}{2i+1}P_{i+1}^s\right\}\right]=0,$$

$$\Sigma\left[\beta_i^s\left\{-i(i+1)-\sigma\right\}P_i^s+\frac{4ma}{\gamma\sigma^2}C_i^sP_i^s\right]=0,$$

$$\Sigma\left[b_i(C_i^s-E_i^s)P_i^s+\alpha_i^s\left\{\frac{(i-s+1)(\sigma+i(i-1))}{2(2i+1)}P_{i+1}^s\right.\right.$$
$$\left.\left.+\frac{(i+s)(\sigma+(i+1)(i+2))}{2(2i+1)}P_{i-1}^s\right\}-\beta_i^s s^2P_i^s\right]=0.$$

Since these equations must be true identically, the coefficients of P_i^s in each of them must vanish. Therefore

$$\left.\begin{aligned}&\alpha_i^s\{\sigma-i(i+1)\}+2\sigma\left\{\beta_{i+1}^s\frac{i+s+1}{2i+3}+\beta_{i-1}^s\frac{i-s}{2i-1}\right\}=0,\\&-\beta_i^s\{\sigma+i(i+1)\}+\frac{4ma}{\gamma\sigma^2}C_i^s=0,\\&b_i(C_i^s-E_i^s)+\alpha_{i-1}^s\frac{(i-s)[\sigma+(i-1)(i-2)]}{2(2i-1)}\\&+\alpha_{i+1}^s\frac{(i+s+1)[\sigma+(i+2)(i+3)]}{2(2i+3)}-\beta_i^s s^2=0.\end{aligned}\right\} \quad . \quad (27)$$

Solution for tesseral oscillations. If we eliminate the α's and β's from the third equation (27) by means of the first two, we find

$$\xi_{i-2}^sC_{i-2}^s-L_i^sC_i^s+\eta_{i+2}^sC_{i+2}^s=\frac{\gamma b_i}{4ma}E_i^s, \quad . \quad . \quad (28)$$

where

$$L_i^s=\frac{s^2}{\sigma^2[\sigma+i(i+1)]}+\frac{(i^2-s^2)[\sigma+(i-1)(i-2)]}{(4i^2-1)[\sigma-(i-1)i][\sigma+i(i+1)]}$$
$$+\frac{[(i+1)^2-s^2][\sigma+(i+2)(i+3)]}{[4(i+1)^2-1][\sigma-(i+1)(i+2)][\sigma+i(i+1)]}-\frac{\gamma b_i}{4ma}$$

$$\xi_{i-2}^s=\frac{-(i-s)(i-s-1)}{(2i-1)(2i-3)[\sigma-(i-1)i]},$$

$$\eta_{i+2}^s=\frac{-(i+s+1)(i+s+2)}{(2i+3)(2i+5)[\sigma-(i+1)(i+2)]}.$$

This equation amongst the C's is available for all values of i, provided that C_{-1}, E_{-1}, C_0, E_0 are regarded as being zero.

As in the case of the zonal oscillations, the equations with odd suffixes separate themselves from those with even suffixes, so that the two sets may be treated independently of one another.

The equation (28) might be treated by a process exactly parallel to that followed in § 8, but as the numerical computations would then become very laborious, it is well to adopt a modification of the procedure.

Second form of solution. It is obvious that the function L_i^s may be split up into partial fractions containing σ^2, σ, $\sigma-i(i-1)$, $\sigma-(i+1)(i+2)$ in the denominators, and ξ_{i-2}^s, η_{i+2}^s are already clothed in that form. When this is done it will be found that the equation may be written as follows:—

$$\frac{i-s}{(2i-1)[i(i-1)-\sigma]}\left\{\frac{i-s-1}{2i-3}C_{i-2}^s+\frac{(i-1)^2}{i^2}\frac{i+s}{2i+1}C_i^s\right\}$$
$$\left\{\frac{s^2}{\sigma^2}\frac{[i(i+1)-\sigma]}{i^2(i+1)^2}-\frac{\gamma b_i}{4ma}\right\}C_i^s$$
$$+\frac{i+s+1}{(2i+3)[(i+1)(i+2)-\sigma]}\left\{\frac{i+s+2}{2i+5}C_{i+2}^s+\frac{(i+2)^2}{(i+1)^2}\frac{i-s+1}{2i+1}C_i^s\right\}$$
$$=\frac{\gamma b_i}{4ma}E_i^s.$$

If now we write for brevity

$$M_i^s=\frac{s^2}{\sigma^2}[i(i+1)-\sigma]-i^2(i+1)^2\frac{\gamma b_i}{4ma},$$

$$N_i^s=i(i+1)-\sigma,$$

and define a new function D_i^s by the equation

$$\frac{(i+1)^2(i-s)}{2i-1}C_{i-1}^s-N_i^sD_i^s+\frac{i^2(i+s+1)}{2i+3}C_{i+1}^s=0, \quad . \quad (29)$$

our equation may be written

$$\frac{(i+1)^2(i-s)}{2i-1}D_{i-1}^s-M_i^sC_i^s+\frac{i^2(i+s+1)}{2i+3}D_{i+1}^s=i^2(i+1)^2\frac{\gamma b_i}{4ma}E_i^s \quad (30)$$

Free waves. As in the case of the zonal oscillations, we shall in the first instance only consider the free oscillations. Accordingly, it will now be assumed that there is no disturbing force, so that E_i^s will be zero.

If for brevity we write

$$\alpha_i^s=\frac{i^2(i+2)^2(i+s+1)(i-s+1)}{(2i+1)(2i+3)},$$

the equations (29) and (30) may be written in the alternative forms

$$\frac{(i+1)^2(i-s)}{2i-1}\left(\frac{C_{i-1}^s}{D_i^s}\text{ or }\frac{D_{i-1}^s}{C_i^s}\right)$$
$$=(N_i^s\text{ or }M_i^s)-\frac{\alpha_i^s}{\frac{(i+2)^2(i-s+1)}{2i+1}\left(\frac{D_i^s}{C_{i+1}^s}\text{ or }\frac{C_i^s}{D_{i+1}^s}\right)} \quad . \quad (31)$$

By continued application of these two formulæ alternately

$$\frac{(i+1)^2(i-s)}{2i-1}\frac{D_{i-1}^s}{C_i^s}=M_i^s-\frac{\alpha_i^s}{N_{i+1}^s-}\ \frac{\alpha_{i+1}^s}{M_{i+2}^s-}\ \frac{\alpha_{i+2}^s}{N_{i+3}^s-}\ldots \quad . \quad (32)$$

Again, the same two equations may be written

$$\frac{i^2(i+s+1)}{2i+3}\left(\frac{C_{i+1}^s}{D_i^s}\text{ or }\frac{D_{i+1}^s}{C_i^s}\right)$$
$$=(N_i^s\text{ or }M_i^s)-\frac{\alpha_{i-1}^s}{\frac{(i-1)^2(i+s)}{2i+1}\left(\frac{D_i^s}{C_{i-1}^s}\text{ or }\frac{C_i^s}{D_{i-1}^s}\right)} \quad . \quad (33)$$

By continued application of these two formulæ alternately

$$\frac{i^2(i+s+1)}{2i+3}\frac{D_{i+1}^s}{C_i^s}=M_i^s-\frac{\alpha_{i-1}^s}{N_{i-1}^s-}\ \frac{\alpha_{i-2}^s}{M_{i-2}^s-}\ \frac{\alpha_{i-3}^s}{N_{i-3}^s-}\ldots \quad . \quad (34)$$

But the second general equation of condition (30), with $E_i^s=0$ is

$$\frac{(i+1)^2(i-s)}{2i-1}\frac{D_{i-1}^s}{C_i^s}+\frac{i^2(i+s+1)}{2i-1}\frac{D_{i-1}^s}{C_i^s}-M_i^s=0.$$

Therefore

$$M_i^s-\frac{\alpha_i^s}{N_{i+1}^s-}\ \frac{\alpha_{i+1}^s}{M_{i+2}^s-}\ldots\text{ ad inf.}$$
$$-\frac{\alpha_{i-1}^s}{N_{i-1}^s-}\ \frac{\alpha_{i-2}^s}{M_{i-2}^s-}\ldots=0 \quad . \quad . \quad . \quad (35)$$

This is the equation from which the frequency of the oscillations may be determined. It may, however, be arranged in another form, for if we had proceeded from (33) we should have obtained a formula like the foregoing in which every M would be replaced by an N, and every N by an M.

In both of these forms the fraction with ascending suffixes extends to infinity, and that with descending suffixes ends with M_s^s or N_s^s.

For the symmetrical types of oscillation, if we use (35) we must suppose $i-s$ to be even, whereas if we use the second form $i-s$ must be supposed odd. The reverse will of course be the case for the unsymmetrical types.

Let us write

Frequency equation.

$$e_i^s=\frac{\alpha_{i-1}^s}{M_i^s-}\ \frac{\alpha_i^s}{N_{i+1}^s-}\ \frac{\alpha_{i+1}^s}{M_{i+2}^s-}\ldots\text{ ad inf.}$$

f_i^s = the same with M and N interchanged.

$$E_i^s=\frac{\alpha_i^s}{M_i^s-}\ \frac{\alpha_{i-1}^s}{N_{i-1}^s-}\ \frac{\alpha_{i-2}^s}{M_{i-2}^s-}\ldots.$$

F_i^s = the same with M and N interchanged.

The E_i^s used here is merely an abbreviation for a certain continued fraction, and must not be confused with the previous E_i^s.

Then the two forms of the frequency equation are

$$\left.\begin{aligned}M_i^s-F_{i-1}^s-f_{i+1}^s=0\\N_i^s-E_{i-1}^s-e_{i+1}^s=0\end{aligned}\right\} \quad . \quad . \quad . \quad . \quad (36)$$

The periods of oscillation are determinable from either of these. As a first approximation, the E, F, e, f fractions may be taken as zero, so that $M_i^s=0$, $N_i^s=0$. We shall see that these two afford, in fact, first approximations to different roots of the equation.

Then, since $\sigma=\frac{s}{f}$, these approximate equations are

$$\left.\begin{aligned} f^2\left[i(i+1)-\frac{s}{f}\right]-i^2(i+1)^2\frac{\gamma b_i}{4ma}=0,\\ i(i+1)-\frac{s_1}{f}=0.\end{aligned}\right\} \quad . \quad . \quad (37)$$

The first is a quadratic equation, with a positive and a negative root; the second has the solution $\frac{s}{i(i+1)}$.

We now denote the "speed" of the tide by λ, so that $\lambda=2nf$. Then since m is n^2a/g, it follows that the first of (37) may be written

$$i(i+1)\lambda^2-2ns\lambda-i^2(i+1)^2\frac{\gamma b_i g}{a^2}=0. \quad . \quad . \quad (38)$$

If, therefore, n vanishes we still have two roots, but they become numerically equal to one another.

But the second of (37) may be written $\lambda=\frac{2ns}{i(i+1)}$, and this root vanishes with n.

Since the positive root corresponds to a westward wave, and the negative root to an eastward wave, we see that there are eastward and westward waves which tend to become identical in period as the rotation slackens. But there is also a westward wave which tends to have an infinite period when the rotation vanishes; that is to say, it becomes a steady motion. We have already adverted to the case of steady motion in the case of the zonal oscillations, but that steady motion differs from the one which we are now considering, in that it can subsist as such without supposing the diurnal rotation to vanish. When the E, F, e, f are not treated as zero, that is to say, when we go on to a second approximation, the motions are found to possess the same characteristics as in these two first approximations.

Form of waves. In order to find the type of motion we have the two equations (32) and (34), which may be written

$$\left.\begin{aligned} \frac{(i+1)^2(i-s)}{2i+1}\frac{D^i_{i-1}}{C^i_i}=M^i_i-f^i_{i+1}=F^i_{i-1},\\ \frac{i^2(i+s+1)}{2i+3}\frac{D^i_{i+1}}{C^i_i}=M^i_i-F^i_{i-1}=f^i_{i+1}.\end{aligned}\right\} \quad . \quad . \quad (39)$$

It is clear from the manner in which the equations (39) were derived that there are two other similar equations with the C's in the numerators. We thus have the four equations

$$\left.\begin{aligned} \frac{C^i_i}{D^i_{i-1}}=\frac{2i+1}{(i-1)^2(i+s)}e^i_i=\frac{(i-s)(i+1)^2}{(2i-1)f^i_{i-1}},\\ \frac{C^i_i}{D^i_{i+1}}=\frac{2i+1}{(i+2)^2(i-s+1)}E^i_i=\frac{(i+s+1)i^2}{(2i+3)f^i_{i+1}}.\end{aligned}\right\} \quad . \quad . \quad (40)$$

From these it is easy to deduce

$$\left.\begin{aligned} C^i_{i-2}=C^i_i\frac{(2i-1)(2i-3)}{(i-s)(i-s-1)i^2(i+1)^2}E^i_{i-2}F^i_{i-1},\\ C^i_{i+2}=C^i_i\frac{(2i+3)(2i+5)}{(i+s+1)(i+s+2)i^2(i+1)^2}e^i_{i+2}f^i_{i+1}.\end{aligned}\right\} \quad . \quad (41)$$

By successive applications of (41) all the C's of the series C^i_{i-2r}, C^i_{i+2r}, may be expressed in terms of C^i_i, which is the arbitrary constant of the solution. It seems natural to adopt this form for the solutions corresponding to the type $M^i_i=0$. It is clear that for the symmetrical oscillations $i-s$ must be even, whilst for the unsymmetrical ones it must be odd.

If we are finding the solution of the type $N^i_i=0$, it will be best to proceed as follows. Writing $i+1$ for i in (41), we obtain C^i_{i-1} and C^i_{i+3} in terms of C^i_{i+1}.

Now

$$C^i_{i+1}=D^i_i\frac{2i+3}{i^2(i+s+1)}e^i_{i+1}=D^i_i\frac{(i-s+1)(i+2)^2}{(2i+1)f^i_i},$$

and therefore we may express C^i_{i-1} and C^i_{i+3} in terms of D^i_i. Hence all the C's of the series C^i_{i-2r-1}, C^i_{i+2r+1} may be expressed as terms of D^i_i, which is the arbitrary constant of the solution. In this case the symmetrical oscillations correspond with $i-s$ an odd number, and the unsymmetrical with $i-s$ an even number.

The numerical solutions obtained by Mr Hough show that for a shallow ocean and for the higher harmonics the eastward and westward wave of the first class (derived from the M^i_i form) have periods which tend to equality as the order of the harmonic increases. This result may be foreseen from the form of the quadratic (38), because the augmentation of i tends to make the first and last terms important compared with the middle term; thus the increase of i gives a result similar to that due to the diminution of n, and if n, the angular velocity, vanishes, the two roots become numerically identical. But for the harmonics of low order the velocities of the two waves are very different. For example, in an ocean 7260 feet deep the westward wave corresponding to $i=2$, $s=2$, has a period of eighteen hours, whilst the period of the eastward wave is thirty-eight and a half hours. But the westward wave of the second class (derived from the N^i_i form) has in all cases a long period, and the period increases with the order. This result is clearly in accordance with what was to be expected from the first approximation $\lambda=2ns/i(i+1)$. For example, for the ocean of 7260 feet in depth when $s=1$, $i=1$, the period is one day thirteen hours, but when $s=1$, $i=3$ the period is $26\frac{1}{2}$ days.

§ 10. *Forced Oscillations or Tides.*

We will now consider, but without going into details, the forced oscillations which correspond with the tides generated by the moon and sun. ***Forced tesseral oscillations.***

The equation of condition amongst the C's is given in (28), namely,

$$\xi^i_{i-2}C^i_{i-2}-L^i_iC^i_i+\eta^i_{i+2}C^i_{i+2}=\frac{\gamma b_i}{4ma}E^i_i,$$

and all the E's excepting, say, E^i_i are to be zero.

Omitting the superscript s for brevity, the equations are

$$\begin{aligned} -L_sC_s+\eta_{s+2}C_{s+2} &=0,\\ \xi_sC_s-L_{s+2}C_{s+2}+\eta_{s+4}C_{s+4} &=0,\end{aligned}$$

and so on; one of the series having the zero on the right replaced by $\frac{\gamma b_s}{4ma}E_s$.

It follows from the same arguments as were adduced in the article on TIDES, § 16, that the limit of C_j is zero when j is infinity.

The equations amongst the C's may be written in the two forms

$$\left.\begin{aligned} \xi_{j-2}\frac{C_{j-2}}{C_j}=L_j-\xi_j\eta_{j+2}\left\{\frac{1}{\xi_jC_j/C_{j+2}}\right\},\\ \eta_{j+2}\frac{C_{j+2}}{C_j}=L_j-\xi_{j-2}\eta_j\left\{\frac{1}{\eta_jC_j/C_{j-2}}\right\},\end{aligned}\right\} \quad . \quad . \quad (42)$$

in every case except when $j=s$, and then the right-hand side of each equation contains the term $+\frac{\gamma b_i}{4ma}\frac{E_s}{C_s}$.

By continued application of these formulæ we may write the right-hand sides in the form of continued fractions—say H_{j-2}, K_{j+2}.

Thus

$$\begin{aligned} \xi_{j-2}\frac{C_{j-2}}{C_j}&=L_j-H_{j-2},\\ \eta_{j+2}\frac{C_{j+2}}{C_j}&=L_j-K_{j+2},\end{aligned}$$

provided that j is not equal to i.

In the particular case where $j=i$ the right-hand side of each equation may still be expressed by the continued fractions H, K, but the additional term must be added. Thus the equation corresponding to $j=i$ is

$$C_i(H_{i-2}-L_i+K_{i+2})=\frac{\gamma b_i E_i}{4ma}.$$

Hence C_i is determined, and then all the other C's are easily determinable as multiples of it.

It follows from this that h, the semi-range of the tide, will have a common factor $\frac{\gamma b_i E_i}{4ma\,(H_{i-2}-L_i+K_{i+2})}$; ***Factor of kinetic augmentation.*** and we see that $\frac{1}{H_{i-2}-L_i+K_{i+2}}$ must be regarded a coefficient of kinetic augmentation, so that if the period of the force coincides with that of any one of the free oscillations the amplitude of the tide becomes infinite. We refer the reader to Mr Hough's paper for the numerical results exemplifying the lunar and solar tides in oceans of various depths. As we have already said, they do not differ more widely from those obtained in the article on TIDES than was to be expected from the introduction of the attraction of the ocean on itself; but the fact that Mr Hough's solution contains that factor of kinetic augmentation, which must occur in every complete solution of a problem involving forced oscillations, renders his solution immensely superior to the older one. (G. H. D.)

Tidore, an island of the East Indian Archipelago, situated in 0° 45′ N. and 127° 23′ E. In area, volcano, liability to earthquakes, climate, and products it resembles Ternate. By an agreement of 1879 the sultan exercises authority over some parts of Jilolo, the Papoea Islands, the western half of New Guinea, and the islands in

Geelvink Gulf. The town of Tidore is the seat of the sultan and of a Dutch Controleur (Resident or Commissioner or Agent). The inhabitants live by agriculture (jagung, cotton, tobacco, and nutmegs) and fishing.

Tiele, Cornelis Petrus (1830–1902), Dutch theologian and scholar, was born at Leyden on the 16th of December 1830. He was educated at Amsterdam, first studying at the Athenæum Illustre, as the communal high school of the capital was then named, and afterwards at the seminary of the Remonstrant Brotherhood. He was destined for the pastorate in his own brotherhood, which, after steadily declining for a considerable period, increased its influence in the second half of the 19th century by widening the somewhat inelastic tenets of the original Dutch Methodists, which had caused many of the advanced clergymen of the Lutherans and Calvinists to secede and go over to the Remonstrants. Tiele certainly had advanced religious views himself, which he early enunciated as a Remonstrant pastor from the pulpit, both at Moordrecht (1853) and at Rotterdam (1856). His earnest eloquence and deep learning attracted attention, and upon the removal of the seminary of the brotherhood from Amsterdam to Leyden in 1873, Tiele was appointed one of its leading professors. In 1877 followed his appointment at the University of Leyden as professor of the science of religion, a chair specially created for him. Of the many learned works which have constituted Tiele one of the leading authorities in Europe upon these matters, the *Vergelijkende Geschiedenis van de Egyptische en Mesopotamische Godsdiensten* ("Comparative History of the Religions of Egypt and Mesopotamia," Amsterdam, 1872), and the *Geschiedenis van den Godsdienst* ("History of Religion," Amsterdam, 1876; new edition, Amsterdam, 1891), have been translated into English, the former by James Ballingall (London, 1878–1882), the latter by J. E. Carpenter (London, 1877), under the title of "Outlines of the History of Religion" (French translation, Paris, 1885; German translation, Gotha, 1895). A French translation of the *Comparative History* was published in Paris in 1882. Other works by Tiele are:—*De Godsdienst van Zarathustra, van het Ontstaan in Baktrië, tot den Val van het Oud-Perzische Rijk* ("The Religion of Zoroaster, from its origin in Bactria to the Fall of the old Persian Empire," Amsterdam, 1864) [this work is now embodied, but much enlarged and improved by the latest researches of the author, in the *History of Religions* (vol. ii. part ii., Amsterdam, 1901), a part which appeared only a short time before the author's death]; *Die Assyriologie und ihre Ergebnisse für die vergleichende Religionsgeschichte* (Leipzig, 1877); *Babylonisch-Assyrische Geschichte* (in two parts, Leipzig, 1886–88); *Western Asia, according to the most Recent Discoveries* (London, 1894). A volume of Tiele's sermons appeared at Haarlem in 1865, and a collection of his poems in 1863. He also edited the poems of his friend, the genial and witty de Genestet. Tiele was best known to English students by his *Outlines* and the Gifford Lectures "On the Elements of the Science of Religion," which he delivered in 1896–98 at Edinburgh University, and which attracted a good deal of attention at the time. They subsequently appeared simultaneously in Dutch at Amsterdam, in English in London and Edinburgh (1897–1899, 2 vols.). Edinburgh University in 1900 conferred upon Tiele the degree of D.D. *honoris causâ*, an honour bestowed upon him previously by the Universities of Dublin and Bologna. He was also a fellow of at least fifteen learned societies in Holland, Belgium, France, Germany, Italy, Great Britain, and the United States. He died on 11th January 1902. In 1901 he had resigned his professorship at Leyden University. Tiele's zeal and power for work were as extraordinary as his vast knowledge of ancient languages, peoples, and their religions, upon which his researches, according to the undisputed testimony of his lifelong friend and fellow-worker in England, Max Müller, have shed an entirely new and most vivid light. Equally remarkable were the breadth of his religious views, his command over facts, and the gift of exposition, whether writing or speaking. With Kuenen and Scholten, amongst others, he founded the "Leyden School" of modern theology.

His brother, Pieter Anton Tiele (1834–1888) acted for many years as the librarian of Utrecht University, and distinguished himself by his bibliographical studies, more especially by his several works on the history of colonization in Asia. Among these the most noteworthy are: *De Opkomst van het Nederlandsch Gezag in Oost-Indië* ("The Rise of Dutch Power in Netherlands India," 1886); *De Vestiging der Portugeezen in Indie* ("The Portuguese in India," 1873), and other books on the early colonization struggles of the Portuguese in the Malay Archipelago. (H. Ti)

Tientsin, a treaty port in the province of Chihli, China, 70 miles south-east of Peking, of which it is the port. It occupies a position of great importance as the seat of the trade of north China. The importance of this position has been enhanced by the railways connecting it with Peking on the one hand and with Shanhaikuan and Manchuria on the other. It will be still further enhanced by the prospective opening of the main trunk line from Peking southwards. In 1899 the total trade of the port was H. taels 77,604,000 (£11,640,000). The native population is stated to be 950,000, but this is probably over the mark. Among local industries the distillation of spirits, usually called Chinese wine, made from millet, holds a principal place, as does also the manufacture of carpets and rugs made of camels' wool. The chief exports are wool, coal, bristles, skins, furs, &c. The British concession, in which the trade centres, is situated on the right bank of the river Peiho below the native city, and occupies an area of some 200 acres. It is held on a lease in perpetuity granted by the Chinese Government to the British Crown, which sublets plots to private owners in the same way as is done at Hankow. The local management is entrusted to a municipal council organized on lines similar to those which obtain at Shanghai. Besides the British concession there are a French concession and a German concession, situated the one above the other below the British. The German concession was negotiated in 1895, but so far has not been utilized to any great extent. During the long period 1874–94, when Li Hung-Chang was viceroy of Chihli and *ex officio* superintendent of trade, he made Tientsin his headquarters and the centre of his experiments in military and naval education. As a consequence the city became the chief focus of enterprise and foreign progress. Having arrogated to himself the practical control of the foreign policy of the nation, his yamen became the scene of many important negotiations, and attracted distinguished visitors from all parts of the globe. The loss of prestige consequent on the Japanese war brought about the retirement of Li, and with it the political importance of Tientsin ceased. Both the foreign concessions and the native city suffered severely during the hostilities resulting from the Boxer movement in June–July, 1900. (For a fuller account of these events see China: *History*.)

Tierra del Fuego.—The boundary between the Argentine Republic and Chile has been settled in such a manner that the Argentine holds that part of the great

island, or Tierra del Fuego properly so-called, which is situated to the east of the meridian of Cape Espiritu Santo, up to the middle of Beagle Channel; and Chile holds all the western part of that island and the other numerous islands to the west and to the south of Beagle Channel. The archipelago to the south of Magellan Strait and to the north of Cape Horn, known by the general name of Tierra del Fuego, is controlled by both countries, the Argentine side as the Territory of Tierra del Fuego, and the Chilian as part of the Territory of Magallanes. Knowledge of these lands has increased considerably, and their reputation for dreariness has been favourably modified. The climate in the eastern and southern regions is not so rigorous as was believed, there are no barren lands, the soil is fertile and can support fruitful industries, and the aborigines are far from being so dangerous as they were once generally considered to be.

The western part of the archipelago of Tierra del Fuego, *i.e.*, to the south of Magellan Strait, constituted by the continuation to the south of the Cordillera de la Costa of Chile and of the Cordillera of the Andes, has not been explored lately, and there is very little to be told concerning it. Small surveys on these fjords have shown that several of the larger islands are cut by channels which separate them into smaller ones, while in other cases the low valleys which unite the mountains and hills are only the result of post-Glacial deposits that have filled part of the former channels, these islands being only the summits of an old continuous half-submerged mountain chain. Sir Martin Conway ascended Mount Sarmiento (7200 feet) and ascertained that it is not a volcano as it is sometimes called. At Dawson Island the Chilian Government has established some settlements, and the Roman Catholic Mission there tries to civilize the Alakaluf Indians by means of school and workshop.

The eastern and greater island has been better explored. In its principal extension it is formed by the continuation of the Tertiary beds of the Patagonian tableland cut by the transversal depression of Magellan Strait and by the low land extending from Useless Bay on the west to San Sebastian Bay on the east, of so recent origin that there exist still some salt lakes, this depression being represented in the old charts as an inter-oceanic passage for small boats. This tableland is covered with morainic material, and as the climate is damper here than in the northern lands of eastern Patagonia, it is more useful for colonization. However, although in 1880 numerous prospectors discovered extensive deposits of alluvial gold, its exploitation has not been generally successful, and farms have taken the place of mines. At the end of 1899 1200 square miles had been occupied by cattle and sheep on the Argentine side, and about the same extent on the Chilian. The price of land has reached £100 per square mile, the results of the first experiments on the farms showing that the cattle industry is very profitable. The gold industry is limited now to very small areas, principally in the southern part of the island.

The undulating tableland has an average height of 300 feet above the sea, and its climate, however cold in winter—in 1892 and 1893 the temperature reached 12·6° F.—allows of the cultivation of barley, oats, and occasionally potatoes, which, however, grow better in Beagle Channel. To the south the tableland is higher and more broken, being drained by the rivers Silva and Grande, amongst other smaller ones, the Grande being navigable in some parts by small craft. To the west and south-west the general character of the land changes; the ends of the Tertiary beds are raised in small hills and Mesozoic rocks appear, forming broken ridges of the Pre-Cordillera, a name given on the continent to the ridges which precede, to the east, the Andes. There appears the Antarctic forest in which predominates the *Fagus antarctica* and *F. betuloides*, *Drymis Winteri*, *Berberis ilicifolia*, *Pernettia*, *Desfontainia* and *Philesia buxifolia*. Two lakes receive the waters of these mountains and hills, Lake Solier and Lake Fagnano. Lake Fagnano is only 180 feet above the sea, and its depth reaches 700 feet. To the south of the lake rises the south-eastern prolongation of the Cordillera of the Andes, with ridges of a uniform height of 3500 feet, in which predominate crystalline schists which do not seem to be very old. Some peaks due to Tertiary granite break the uniformity, such as Mount Sarmiento, Mount Darwin, of which two peaks have been measured (6201 and 7054 feet), and Mount Olivaia (4324 feet). Deep valleys, which seem to be only the prolongation of fjords, penetrate into the chain in the southern slope where exist several ports in which settlements have commenced. Yendegaia, Lapatia, and Ushuaia Bays are among the larger, and present magnificent landscapes, with their glaciers and woods. Ushuaia, being the site of the capital of the Argentine Territory, is developing rapidly, having regular communication by monthly steamers with Buenos Aires, while smaller steamers serve the different settlements along the coast. Cattle farms prosper along Beagle Channel, the timber industry is growing, lignite seams have been discovered, and alluvial gold is washed principally at Slogget Bay. These regions, as they become more known, will invite the attention of tourists by their proximity to the most sublime scenery. South of the Beagle Channel partial exploration was conducted by the French Mission du Cap Horn in 1882–83, and the geological foundations are better known, being there granite and basic volcanic rocks. Staten Island to the east of Tierra del Fuego has been settled by the Argentine Government, and there are a prison and lighthouse in St John Harbour. A first-class permanent meteorological and magnetic station is being established there by the same Government.

The aborigines are decreasing rapidly in the whole archipelago, and the Rev. Thomas Bridges, who, as missionary first and then as farmer, resided thirty years there, says that when he arrived he calculated the population to be 10,000, but in 1892 there were only about 1000 (Alakalufs, 100; Yagans, 320; Onas, 600). With the settlement of the great island, which is now generally called Onisia, leaving the name of Tierra del Fuego to the archipelago, the Onas tribe is becoming better known. Undoubtedly, however, among these Indians are many that recall some Patagonian types; it seems that they are not the same as the Tehuelche type generally known, but that they pertain to one of the races that in earlier times existed in Patagonia. Their language is closely allied with the one called Old Tehuelche. The Onas live only in the island of Onisia. The Yagans seem less distantly related to the Onas than has been supposed, and probably are a mixed race composed of Alakalufs and Onas. The languages of the Yagans and the Alakalufs are alike in many particulars.

Tietjens, Thérèse Johanne Alexandra (1831–1877), Hungarian soprano vocalist, was born at Hamburg on 17th July 1831. Her voice was trained at Hamburg, where she made a successful *début* in 1849 as Lucrezia Borgia in Donizetti's opera. Thence she proceeded to Frankfort and Vienna. She sang for the first time in London in 1858, appearing as Valentine in *Les Huguenots*. Her success was so great that for the rest of her life she made England her home, and soon gained as brilliant a reputation in concert and oratorio work as she had already won upon the stage. Her voice was a dramatic soprano of magnificent quality, and her gifts as an actress were unequalled. Her most famous parts were Fidelio, Medea (in Cherubini's opera), Donna Anna (in *Don Giovanni*), but she touched nothing that she did not adorn. She had endeared herself to the English people as much by her virtues as by her artistic gifts, and her death in London on 3rd October 1877 was deplored as a national calamity.

Tiffin, a city of Ohio, U.S.A., capital of Seneca county, on the Sandusky river, and the Baltimore and Ohio, the Cleveland, Cincinnati, Chicago, and St Louis, and the Pennsylvania railways, in the northern part of the state, at an altitude of 746 feet. Heidelberg

University, situated here, had in 1899 a faculty of 28 teachers, and was attended by 308 students, of whom 104 were women. Population (1890), 10,801; (1900), 10,989, of whom 1168 were foreign-born.

Tiflis, a government of Transcaucasia, Russia, occupying the eastern portion of the great valley which stretches between the main Caucasus range and the Transcaucasian plateau from the Mesques Mountains eastwards, comprising within its boundaries both the southern slopes of a long stretch of the Caucasus Mountains and the northern slopes of the Anti-Caucasus, which rise to from 5000 to 10,000 feet. A portion of it, namely, the district of Akhaltsykh, penetrates, indeed, right over the Transcaucasian plateau, including the high valley of the Upper Kura, between the Wakhan Mountains and the Anti-caucasus. The land is rich in minerals, but hitherto most of them have been allowed to remain practically idle. Only copper is extracted at Alaverd and Akhtal. The government is watered by the Kura and its tributaries, Lyakhva, Aragva, Iora, and Alazañ, all of whose waters are largely used for irrigation; but in the lower parts of the great valley there are extensive waterless steppes, Shirak and Kara-ez, on the left bank of the Kura, which are chiefly inhabited by nomad Tatars. The area of the government is 15,306 square miles (16,847 with the Zakataly district), and the population, which was 599,300 in 1869, numbered 1,040,943 (domiciled only) in 1897, 470,173 of whom were women, and 207,294 urban. The inhabitants are very mixed in race: the bulk of them are Georgians, whose numbers were estimated by Caucasian statisticians at 396,673 out of a total population of 808,143 in 1894–96, and to whom belong also in reality the Pshaves (9155), the Imeretians (8970), the Tushins (5624), the Khevzurs (6560), the Gurians, the Mingrelians, &c.; Armenians were estimated to number 193,610, Ossets 72,420, Azerbaijan Tatars 68,345, Russians 35,750, Greeks 22,171, Germans 5066, and west and east Caucasian mountaineers 4700. The annual birth-rate is 36 per 1000, the death-rate 23 per 1000; hence the natural increase of population is nearly 12,400 yearly. The government is divided into nine districts, the chief towns of which are: Tiflis (see below), Akhalkalaki (5443), Akhaltsykh (15,387), Dusheti (2456), Gori (10,457) Signakh (8998), and Telav (11,810). The districts of Borchala and Zioneti have no towns. Agriculture is the main occupation of the people, and has reached a very high standard. Land is sold and rented at very high prices, such as are obtained only in the most populous parts of western Europe. The crops of 1897, which may be considered as an average year, were: wheat, 769,000 qrs.; rye, 2600 qrs.; oats, 11,550 qrs.; barley, 413,000 qrs.; millet, 18,800 qrs.; Indian corn, 143,600 qrs.; rice, 3900 qrs.; various cereals, 18,700 qrs.; also potatoes, 71,000 qrs. Large portions of the cultivated area are covered with vineyards. Cattle-breeding is extensively carried on in the steppes. There is a great variety of domestic industries, and the natives attain a high degree of perfection in the manufacture of leather and metallic goods, felt, woollen stuffs, and gold embroidery. Factories, however, are of little importance; the 3800 industrial establishments employ only 7350 workers, and their aggregate yearly returns amount to little more than 10,000,000 roubles. (P. A. K.)

Tiflis, the capital of Caucasia and of the above government. It is now connected by rail with Poti and Batum (217 miles) on the Black Sea, with Baku on the Caspian Sea (341 miles), with Kars (185 miles) on the Transcaucasian plateau, and, *vid* Baku and Petrovsk, with the railway system of European Russia, which it joins at Beslan, near Vladikavkaz (723 miles). Omnibuses also run regularly across the main range to Vladikavkaz, which by this route is only 133 miles distant. The city has considerably developed, and had, in 1897, 160,645 inhabitants, as compared with 104,024 in 1883. The central part is well built, and contains many handsome structures. There are monuments to the Russian writers Griboyedoff and Lermontoff. It carries on an important trade with Russia, Western Europe, and Persia. (See CAUCASUS.)

Tigré. See ABYSSINIA.

Tigris, a river of Turkey in Asia. Navigation is carried on by large rafts from Diarbekr to Baghdad, and below the latter city by river steamers and sailing craft. The last ascend as far as Samara, but at present no steamers run above Baghdad. The river commences to rise about the middle of November, and is highest in May and June, when its current is about four miles an hour. It is lowest in September, October, and November. Its tributaries, the Khabúr and the Lesser Zab, are navigable for rafts over portions of their courses, and the Diala for sailing vessels as far as Bakuba. During the flood season the Shatt el-Hai canal is navigable for native boats, and the Isa canal, which runs from the Euphrates to the Tigris, for small steamers. During the time of the Abbaside khalifs the Tigris flowed down the Shatt el-Hai canal, and, below Wasit, passed through several channels to the great swamp, el-Batiha, whence its waters ran out through a canal to the Shatt el-Arab. At that period, too, a large canal on the left bank of the river, dating from the time of Chosroes, left the river at Dur, below Tekrít, and re-entered it below the site of Kut el-Amara; whilst the lands on the right bank, north of Baghdad, were irrigated by the Ishakíyeh and Dujeil canals.

Tikhvin, a district town of Russia, in the government of Novgorod, 86 miles north-east of Chudovo station, on the St Petersburg–Moscow railway. It is the head of the Tikhvin system of canals, which connects the Volga with St Petersburg. Over 11,000 vessels, carrying goods valued at £5,000,000, pass through these canals every year, and during the summer the town becomes very animated, its population for a few months being double its normal size. It has several flour-mills and distilleries; also a monastery which has acquired a great reputation in northern Russia. Population (1897), 6631.

Tilburg, a town in the Dutch province of North Brabant, 13 miles east by south of Breda. A railway to 's Hertogenbosch (Bois-le-Duc) was opened in 1881, and there is railway connexion also with Nimeguen, &c., and a steam tramway to Waalwijk. The town has a cloth hall, a new Gothic church, and a higher burgher-school. There are 70 steam and 110 other factories, 80 of them woollen, and 30 leather factories. Population (1901), 41,518.

Tillicoultry, a police burgh of Clackmannanshire, Scotland, at the foot of the Ochil Hills, on the river Devon, 3¾ miles north-north-east of Alloa. There are about a dozen woollen factories, tweeds and shirtings being the staple product. Coal-mining and agriculture are also pursued. It has an institute and library, a session-house and hall in connexion with the parish church, an orphanage, and a public park. Population (1891), 3939; (1901), 3337.

Tilsit, a town of Prussia, province of East Prussia, on the river Niemen, 57 miles by rail south-east of Memel. It has considerable trade, and manufactures of

machinery, soap, oil, vinegar, shoes, tobacco, glass, cheese, &c., besides iron foundries, tanneries, breweries, saw-mills and flour-mills. A bronze statue of the native poet Von Schenkendorf was unveiled in 1890. Population (1885), 22,422; (1900), 34,538.

Timbuktu, chief town of the territory of Timbuktu, southern Sahara, West Africa, on the border of the gently-rising tableland to the north of the swamps and channels connecting with the Niger, and some 9 miles north of the main stream. Its position, which was given by Caillié and Barth at 17° 29′ N. and 5° 27′ W., has been astronomically determined at 16° N. and 5° W. It was occupied by the French in December 1893, and has since formed part of their Sudanese domain. The neighbouring reaches of the Niger had already been visited by gunboats in 1887 and 1890, and after the reduction of Segu and Massina by Colonel Archinard early in 1893, the permanent occupation of Timbuktu became inevitable. Indeed the townspeople, wearied with the internecine strife of the rival Tuareg and Fulah tribes, freely opened their gates to Lieutenant Boiteux as soon as he reached the riverside port of Kabara in command of a small flotilla on 12th December 1893. This first success was followed by some severe reverses at the hands of the turbulent nomads; but since February 1894 the French rule has not been seriously challenged. At that time the population, which had probably exceeded 50,000 under the Mandingan and Songhai empires, had fallen to about 8000, and even now scarcely exceeds 10,000. In 1895 the place was still described as little more than a vast ruin, but under the new order steady revival set in. The people no longer fear to repair their dilapidated dwellings; new streets have been opened; European schools, churches, and other establishments have sprung up; the fortifications, including a fort at Kabara, have been greatly strengthened, and it is proposed to connect the city with the Niger by a regular canal running through the occasionally flooded backwaters of the intervening district. The local industries—cotton-weaving, earthenware, leather work, and embroidery—are of subordinate importance, and the great bulk of the people continue as formerly to be occupied exclusively with trade. The whole traffic of the surrounding lands still converges on Timbuktu, which is described as a vast "exchange" for the products of the north and south, with a transit trade estimated at over £800,000. Considerable quantities of British and German fabrics, hardware, beads, &c., are conveyed across the Sahara from Mogador (Morocco), while two great caravans of 3000 or 4000 camels are yearly charged with salt from the Taudeni district. The imports *viâ* the Sahara average close upon £50,000 annually, and by way of Senegal £20,000 to £25,000. From the south come cereals, gold, wax, ivory, coarse native cotton goods, now brought from the heart of Sudan by steamers plying on the Upper Niger. Cowries, the former currency (2500 = 5 francs), have already been generally replaced by French money, and efforts are being made to oust British and German goods by French wares introduced by the Senegal route. Since 1899 Timbuktu has been the capital of the Territoire de Tombouctou (the French spelling), a very large administrative division which is organized on a military base and is directly dependent on the Governor-General of French West Africa.

(A. H. K.)

Timor, in the Malay (or Indian) Archipelago, the most easterly and the largest of the Lesser Sunda Islands, with a length of 300 miles and a fairly regular breadth of about 60 miles. Though visited by several explorers (Reinwardt, Muller, Riedel, Forbes, and Wichmann), its physical features are imperfectly known, and there is considerable divergence of opinion as to the character of the mountain system of the island, the existence or non-existence of volcanoes, and the geological formations. Little progress has been, or is likely to be, made in the development of the island. How much the climate militates against cultivation will be seen when it is stated that at Kupang, on the south coast, the number of rainy days per month in the six months May to October dwindles from 4 to 1, and finally 0, while the monthly rainfall gradually sinks from a little less than 2 inches to *nil;* the northern districts are somewhat better off, and might do fairly well under a vigorous rule. Though the mineral products are varied, the supply of ores has hitherto proved scanty; besides which the exploitation of the resources of the island in this respect is rendered difficult by the lack of labourers and of water and wood. The area is estimated at about 12,500 square miles, whilst the population is variously placed at 600,000 (Wagner and Supan) and more than 750,000 (Reclus and Vaquinhas). Politically the north-eastern half of the island is Portuguese, as are two small enclaves in the south-western half, the remainder being Dutch.

PORTUGUESE TIMOR includes the neighbouring isle of Pulo Kambing, and has an area of about 7450 square miles. Estimates of the population vary from about 300,000 to over half a million. Dilli, on the north coast, the administrative headquarters and chief settlement, is a very poor little place of some 3000 inhabitants, containing hardly any Europeans apart from the official population. Macao was administratively united to Portuguese Timor till 1896, and still pays a contribution to the revenue. The estimated revenue for 1901–1902 was £25,196 (£7200 from Macao), and the estimated expenditure £36,532. Scarcely any ships visit the colony, except some of the Dutch vessels trading in the archipelago, which call regularly at Dilli. Exports (principally coffee) were valued at £110,000 in 1888, £72,000 in 1890, and £55,000 in 1897, when the imports were valued at about £70,000.

DUTCH TIMOR has an area of a little over 5000 square miles, and a population of about 250,000. Kupang, the chief town not only in the island but in the whole residency, contains some 8000 inhabitants, of whom 145 are Europeans, living in well-built houses, 594 Chinese, and 43 Arabs. In agriculture, European plants have not been successful, and of native products the supply is only sufficient for the home consumption. The export of sandal-wood, ponies, cattle, pinang nuts, &c., amounts in a year to the value of only about £8500. Dutch Timor gives its name to a residency consisting of, besides its own territory, the small adjacent islands, Roti, Peman, &c., the Savu islands, Sumba or Sandalwood island, the Solor and the Allor group of islands, and the eastern half of Flores, the whole lying between 8° 5′ and 11° 5′ S. and 119° 3′ and 125° 15′ E., the total area being 17,698 square miles. It is divided into four administrative districts—Timor, Roti and Savu, Larantuka (eastern Flores), and Sumba. In 1897 the population was officially returned as (approximately) 119,239, of whom 256 were Europeans, 1314 Chinese, and 182 Arabs; but other estimates have placed it as high as 400,000, and even 1,800,000. The number of natives is indeed only conjectural. (See also MALAY ARCHIPELAGO: *Dutch East Indies,* for general information as to government, defence, &c.)

The Anglo-Portuguese Boundary Treaty of 1859 was replaced by one signed at Lisbon in June 1893. The old treaty had proved irksome in many ways, especially in that it left portions of the territory belonging to protected chieftains of both Powers as enclaves within the boundaries of the Portuguese or Dutch parts of the island. This led to frequent disputes and complaints on both sides. In order to obviate such complications in the future, a mixed boundary commission was appointed under the new treaty, which commission has determined new boundaries in Timor that are more satisfactory to the contracting parties than the old ones were. The new treaty contains, moreover, the important stipulation (alluded to under HOLLAND, *Recent History*), that all future disputes relating to the possessions of either Power in Timor, or the decisions of the International Boundary Commission, will be referred to arbitration. Equally important is the declaration, signed by the contracting parties at the same time as the Lisbon treaty, to the effect that either Power will favour the subjects of the other in granting concessions, &c., to the exclusion of all other aliens. Thus Portugal and Holland have mutually secured the exclusive possession of Timor to themselves. Both principles are new, certainly as far as the Malay Archipelago is concerned, and might be applied with advantage in other parts of the Malay Archipelago, where more than one European Power possesses territories and territorial rights. Timor is no longer connected with New Guinea (compare TERNATE).

For the remarkable flying survey of the south coast by the commandant of the *Siboga* expedition, exploring the deep seas and fauna of the Archipelago, see *Bulletin (No. 35) of the Maatschappij ter bevordering van het natuurkun onderzoek der N. I. Kolonien.* In the earlier maps much of the south coast is laid down too far to the south.

(E. DE V.; C. M. K.; H. TI.)

Timor Laut (in Dutch, *Timor Laoet*), or TENIMBAR, a group of islands in the Malay Archipelago, to the S.W. of the Aru islands, between 6° 20′ and 8° 30′ S. and 130° 40′ and 132° 5′ E. They are politically divided into two districts. One is Larat, including the inhabited islands of Larat, Vordate, Molu, and Maro, together with many other islands uninhabited; the other is Sera, including the Sera islands, Selaru, and the southern part of Yamdena, all inhabited. Only Yamdena and Selaru are by the natives called Timor Laut; all the others they call Tenimbar. Vordate, Molu, and south-eastern Yamdena have a maximum height of 820 feet; the rest are low and flat. Ritabel in Larat is the only safe roadstead during the east and west monsoons. The population is estimated at from 12,000 to 13,000 by Riedel, and at 19,342 by Van Hoëvell. The only means of subsistence is the natives' primitive agriculture on a stingy soil, turtle and trepang fishery, and cattle-rearing. The yearly export (trepang, turtle, and kamuning wood) is valued at only from £850 to £1650.

See FORBES. "Three Months' Explorations in the Tenimbar Islands," in *Proceedings of R.G.S.* 1884.—RIEDEL. *De sluik en kroesharige rassen tusschen Selebes en Papua.* 1886.—VAN HOËVELL. "Tanimbar en Timor Laoet-Eilanden," in *Tijdschr. Bat. Gen.*, xxxiii. 1889.

Tin.—Since 1875 a remarkable expansion has occurred in the production and consumption of this metal, which is still the rarest of what are known as the "common" metals. In the year named the world's total production was some 40,000 tons, of which 10,000 tons were produced by Cornwall, 10,000 by the Straits Settlements, about 8000 tons by Banka and Billiton, and about 11,000 tons by Australasia, the greater portion of the latter coming from New South Wales. At present the world's annual production is about 75,000 tons, of which about 46,000 tons come from the Straits Settlements, 14,000 from the Dutch East Indies, 5000 from Australasia (Tasmania now taking the first place amongst these states), 5000 tons from Cornwall, and 5000 tons from Bolivia. There are a few other places where tin is met with, but they are practically unimportant. Tinstone occurs in its matrix, either in or closely associated with fissure veins or disseminated through rock masses. It is also found in the form of rolled lumps and grains in alluvial gravels; it need hardly be said that the latter are secondary deposits, the products of the disintegration of the first-named primary deposits. Throughout the world, primary deposits of tinstone are in or closely connected with granite or acid eruptive rocks of the same type, its mineral associates being tourmaline, fluorspar, topaz, wolfram, and arsenical pyrites, and the invariable gangue being quartz: the only exception to this mode of occurrence is to be found in Bolivia, where the tin ore occurs intimately associated with silver ores, bismuth ores, and various sulphides, whilst the gangue includes barytes and certain carbonates. Over five-sixths of the world's total production is derived from secondary alluvial deposits, but all the tin obtained in Cornwall and Bolivia is from vein mining, while a small portion of that yielded by Australasia comes from veins, and from granitic rocks carrying disseminated tinstone.

Mining and Dressing.—The alluvial deposits are almost invariably worked opencast, those of the Malay Peninsula and Archipelago chiefly by Chinese labour: in a few instances hydraulic mining has been resorted to, and in other cases true underground mining is carried on; but the latter is both exceptional and difficult. The alluvial extracted, which in the Malay Peninsula and Archipelago carries from 5 to 60 ℔ of tinstone (or "black tin," as it is termed by Cornish miners) to the cubic yard of gravel, is washed in various simple sluicing appliances, by which the lighter clay, sand, and stones are removed, and tinstone is left behind comparatively pure, containing usually 65 to 75 per cent. of metallic tin (chemically pure tinstone containing 78·7 per cent.). Lode tin, as tinstone derived from primary deposits is often termed, is mined in the ordinary method, the very hard gangue in which it occurs necessitating a liberal use of explosives. The veinstuff is broken small either by hand or in rock-breakers, and stamped to fine powder in stamp mills, which are practically large mechanically-worked pestles and mortars, the stamp proper weighing from 500 to 1000 ℔. The mineral, crushed small enough to pass a sieve with perforations $\frac{1}{20}$ inch in diameter, leaves the stamps in suspension in water, and passes through a series of troughs in which the heavier mineral is collected; this then passes through a series of washing operations, which leaves a mixture consisting chiefly of tinstone and arsenical pyrites, which is calcined and washed again, until finally black tin containing about 60 to 65 per cent. of metal is left. The crude tinstuff raised in Cornwall carries on an average a little over 2 per cent. of black tin. The Bolivian tin ore is treated by first extracting the silver by amalgamation, &c., and afterwards concentrating the residues; there are, however, great difficulties in the way of treating the poorer of these very complex ores, and several chemical processes for extracting their metallic contents are in course of being worked out.

Smelting.—The dressed ore is smelted by one of two main methods, viz., either in the shaft furnace or the reverberatory; the former is the better suited to stream tin, the latter to lode tin, but either ore can be smelted in either way. Shaft furnace smelting is confined to those parts of the world where charcoal can still be obtained in large quantities at moderate prices. The furnace consists of a shaft, circular (or more rarely rectangular) in plan, into which alternate layers of fuel and ore are charged, an air

blast being generally injected near to the bottom of the furnace through one or more tuyeres. This was the primitive process all over the world; in the East, South America, and similar regions, it still holds its own. In Europe, Australasia, and one large works at Singapore it has been practically replaced by the reverberatory furnace process, first introduced into Cornwall about the year 1700. All tin, except a small quantity produced by the shaft furnace process from exceptionally pure stream tin ore, requires refining by liquation and "boiling" before it is ready for the market.

Tinnevelly, a town and district of British India, in the Madras Presidency. The town is on the left bank of the Tambraparni river, on the other side of which is Palamcotta, the administrative headquarters of the district. It is the terminus of a branch of the South Indian Railway, 444 miles S.W. of Madras. Population (1881), 23,221; (1891), 24,780; municipal income (1897–98), Rs.28,160. It has two cotton mills, with 31,740 spindles, employing 1327 hands. The two colleges, Hindu and Church Mission, had 131 students in 1896–97; the two high schools, 797 pupils. There are also five printing-presses.

The district of TINNEVELLY has an area of 5387 square miles. Population (1881), 1,699,747; (1891), 1,916,095, showing an increase of 13 per cent. after the famine of 1876–78; average density, 356 persons per square mile. In 1891 the native Christians, chiefly Protestants, numbered 145,569, or nearly 8 per cent., a far higher proportion than in any other district of India. In 1901 the population was 2,060,759, showing a further increase of nearly 8 per cent. The land revenue and rates in 1897–98 were Rs.35,69,011, the incidence of assessment being R.1.10.7 per acre; cultivated area, 1,145,900 acres, of which 282,818 were irrigated from tanks, wells, &c., including 44,611 from Government canals; number of police, 1037; boys at school (1896–97), 55,149, being 39·4 of the male population of school-going age, the highest proportion in the province; girls at school, 9418, being 6·4 per cent.; registered death-rate (1897), 25·2 per 1000. The principal crops are rice, millet, other food-grains, cotton, and oil-seeds, with a little tobacco. Coffee is grown on 1284 acres on the slopes of the Travancore hills. The palmyra palm, whose juice yields toddy as well as a coarse sugar, flourishes in certain tracts. The Shanans, or caste of toddy-drawers, have supplied many converts to Christianity. In 1899 their treatment by the Vellalars, or cultivating caste, led to serious riots and bloodshed. The chief irrigation work is the Srivaikuntam anicut, or dam, on the Tambraparni river, on which the capital outlay has been Rs.14,71,924. In 1897–98 the area irrigated was 41,668 acres, and the net profit was Rs.25,527. The South Indian Railway runs through the district, with its maritime terminus at Tuticorin, the chief seaport. In 1897–98 the total sea-borne trade was valued at Rs.3,08,03,307, being just one-tenth of the trade of the province. The chief exports are rice to Ceylon and cotton to Japan and Europe. There are thirteen factories for ginning and pressing cotton, and one rice-cleaning mill.

Tippera (*Tripura*), a native state and British district of India, in the north-east of Bengal. The state is known as Hill Tippera. It represents that portion of the raja's territory that was never conquered by the Mahommedans. The dynasty, which is of great antiquity, was converted to Hinduism many centuries ago; but the people, called Tipperas, still profess an aboriginal religion, similar to the neighbouring hill tribes.

The raja owns an estate of 589 square miles in the British district, where he ranks as an ordinary *zamindar*. His residence is at Agartalla, just within the boundary of Hill Tippera. Area of the state, 4086 square miles; population (1881), 95,637; (1891), 137,442, showing an apparent increase of 43 per cent., due to more accurate enumeration; average density, 34 persons per square mile. In 1901 the population was 167,441, showing a further increase of 22 per cent. The expenditure in 1897–98 was Rs.6,87,430, of which Rs.1,38,000 was devoted to public works. Tolls are levied upon exports of forest produce, cotton, and oil-seeds. The raja's palace and other public buildings at Agartalla were seriously damaged by the earthquake of 12th June 1897.

The British district of TIPPERA (the administrative headquarters are at Comilla) has an area of 2491 square miles; population (1881), 1,514,361; (1891), 1,782,935, showing an increase of nearly 18 per cent., by far the highest rate of increase in Bengal; average density, 716 persons per square mile. Classified according to religion, Mahommedans in 1891 numbered 1,224,336; Hindus, 557,079; Christians, 182, of whom 57 were Europeans; "others," 1338. In 1901 the population was 2,124,869, showing a further increase of 19 per cent., again the highest rate in the province. The land revenue and rates in 1897–98 were Rs.11,77,084; number of police, 377; boys at school (1896–97), 57,435, being 41·9 per cent. of the male population of school-going age; registered death-rate (1897), 26 per 1000. The eastern border of the district is traversed by the Assam–Bengal Railway, with a cross branch from Laksam to Chandpur; but waterways still remain the chief means of communication. The exports are mostly rice, jute, and betel-nuts.

Tipperary, an inland county of Ireland, province of Munster.

Population.—The area of the administrative county in 1900 was 1,050,130 acres, of which 246,353 were tillage, 623,874 pasture, 403 fallow, 26,469 plantation, 35,788 turf bog, 9819 marsh, 67,471 barren mountain, and 39,953 water, roads, fences, &c. The new administrative county under the Local Government (Ireland) Act, 1898, includes the portions of the towns of Clonmel and Carrick-on-Suir formerly situated in Waterford. The population in 1881 was 199,612; in 1891, 173,188; and in 1901, 159,754, of whom 81,075 were males and 78,679 females, divided as follows among the different religions: Roman Catholics, 149,903; Protestant Episcopalians, 8689; Presbyterians, 444; Methodists, 550; and other denominations, 168. The decrease of population between 1881 and 1891 was 13·24, and between 1891 and 1901, 7·7 per cent. The average number of persons to an acre in 1891 was ·16, and of the total population, 133,213 persons inhabited the rural districts, being an average of 99 to each square mile under crops and pasture. The following table gives the degree of education for the principal creeds in 1891:—

	Males.	Females.	Total.	Percentage.			
				Roman Catholics.	Protestant Episcopalians.	Presbyterians.	Methodists.
Read and write.	60,684	58,092	118,776	74·5	93·7	93·1	95·4
Read only . .	6,856	7,788	14,644	9·7	2·9	4·4	2·2
Illiterate . .	11,077	12,630	23,707	15·8	3·4	2·5	2·4

The percentage of illiterates among Roman Catholics in 1881 was 22·7. In 1891 there were 14 superior schools with 750 pupils (Roman Catholics, 662; and Protestants, 88), and 355 primary schools with 27,469 pupils (Roman Catholics, 26,234; and Protestants, 1235). The number of pupils on the rolls of the National Schools on 31st December 1900 was 26,674, of whom 25,518 were Roman Catholics and 1156 Protestants. The following table gives the number of births, deaths, and marriages in various years:—

Year.	Births.	Deaths.	Marriages.
1881	4523	3428	708
1891	3661	3046	659
1900	3296	3053	612

In 1900 the birth-rate per 1000 was 20·6, and the death-rate 19·1. The rate of illegitimacy was 2·3 per cent. of the total births. The total number of emigrants who left the country between 1st May 1851 and 31st December 1900 was 206,377, of whom 106,542 were males and 99,835 females. The chief towns in the county are Clonmel, Carrick-on-Suir, Tipperary, and Nenagh.

Administration.—The county is divided into four parliamentary divisions—North, South, Mid, and East—the number of registered

electors in 1901 being respectively 5994, 5190, 6613, and 6234. The rateable value in 1900 was £686,396. By the Local Government (Ireland) Act, 1898, the fiscal and administrative duties of the two grand juries were transferred to two county councils (one for each Riding), urban and rural district councils were established, and under that Act the county now comprises eight urban and twelve rural sanitary districts.

Agriculture.—The following tables give the acreage under crops, including meadow and clover, and the amount of live stock in 1881, 1891, 1895, and 1900. The figures for 1900 are for the new administrative county:—

Year.	Wheat.	Oats.	Barley, Rye, &c.	Potatoes.	Turnips.	Other Green Crops.	Meadow and Clover.	Total.
1881	14,658	54,348	17,490	34,430	19,892	6612	118,371	265,801
1891	6,275	40,888	22,038	30,316	20,189	8047	116,673	244,426
1895	1,914	42,547	21,131	27,195	20,654	8084	129,191	250,716
1900	2,938	38,699	19,114	24,884	19,789	9466	131,513	246,353

For 1900 the total value of the cereal and other crops was estimated at £1,551,209. The number of acres under pasture in 1881 was 602,912; in 1891, 621,394; and in 1900, 623,874.

Year.	Horses and Mules.	Asses.	Cattle.	Sheep.	Pigs.	Goats.	Poultry.
1881	23,987	12,371	244,029	205,850	74,540	12,952	681,816
1891	33,910	15,091	280,810	272,969	87,695	16,796	661,863
1895	35,226	15,716	268,476	221,859	82,274	15,532	688,476
1900	32,889	17,412	297,218	251,202	73,797	16,050	755,706

The number of milch cows in 1891 was 85,532, and in 1900, 86,505. It is estimated that the total value of cattle, sheep, and pigs for 1900 was £4,311,730, Cork being the only county with a higher figure. In 1900 the number of holdings not exceeding 1 acre was 3625; between 1 and 5, 2714; between 5 and 15, 4413; between 15 and 30, 4801; between 30 and 50, 4035; between 50 and 100, 3414; between 100 and 200, 1480; between 200 and 500, 507; and above 500, 92; total, 25,081. The number of loans issued (the number of loans being the same as the number of tenants) under the Land Purchase Acts, 1885, 1891, and 1896, up to 31st March 1901, was 2585, amounting to £1,152,679. The number of loans for agricultural improvements sanctioned under section 31 of the Land Act, 1881, between 1882 and 1901 was 1095, and the amount issued £77,785. The total amount issued on loan for all classes of works under the Land Improvement Acts from the commencement of operations in 1847 to 31st March 1901 was £235,249.

Tipperary, a town and urban sanitary district in the above county, 110 miles S.W. of Dublin by rail. There are condensed milk and mineral water factories. New Tipperary, which was founded outside the town by Mr William O'Brien during the Plan of Campaign on the Smith-Barry estate, is now practically deserted. Population (1891), 6391; (1901), 6216.

Tipton, a city of Indiana, U.S.A., capital of Tipton county, a little north of the centre of the state, on the Lake Erie and Western Railroad, at an altitude of 872 feet. It is in an agricultural and natural gas region, and has considerable trade. Population (1880), 1250; (1890), 2697; (1900), 3764, of whom 85 were foreign-born.

Tirah Campaign.—The sudden outbreak in 1897 of the Afridi tribes required to be promptly met in order to avert a general conflagration on the Indian frontier. The Afridis had for sixteen years received an annual subsidy from the Indian Government for the safeguarding of the Khyber Pass, in addition to which the Government had maintained for this purpose a local regiment entirely composed of Afridis, who were stationed in the pass. Suddenly, however, the tribesmen rose, captured all the posts in the Khyber held by their own countrymen, and attacked the forts on the Samana Ridge near Peshawar, one of which, Saraghari, made a memorable defence, the entire garrison (composed of Sikhs) dying at their posts. It was estimated that the Afridis and Orakzais could, if united, bring from 40,000 to 50,000 men into the field. The preparations for the expedition occupied some time, and meanwhile the Mohmand rising north-west of the Khyber Pass was first dealt with (see MOHMAND EXPEDITION).

The general commanding was General Sir William Lockhart (*q.v.*), commanding the Punjab Army Corps; he had under him 34,882 fighting men, officers and men, British and native, in addition to 20,000 followers.

Tirah is a fertile valley about 30 miles to the south-west of Peshawar, but cut off almost entirely by ranges of mountains. The district, which no white man had penetrated, was the summer home of the Afridis, whither they retire with their flocks and herds for pasture and agriculture. The frontier post of Kohat was selected as the base of the campaign, and it was decided to advance along a single line. On 18th October the operations commenced, fighting ensuing immediately. The Dargai heights, which commanded the line of advance, were captured without difficulty, but abandoned owing to the want of water. On the 20th the same positions were gallantly stormed, with a loss of 199 killed and wounded. The progress of the expedition, along a wretched track through the mountains, was obstinately contested on 29th October at the Sampagha Pass leading to the Mastura valley, and on the 31st at the Arhanga Pass from the Mastura to the Tirah valley. The force, in detached brigades, now proceeded to traverse the Tirah district in all directions, and to destroy the walled and fortified hamlets of the Afridis. The two divisions available for this duty numbered about 20,000 men. A force about 3200 strong commanded by Brigadier-General (afterwards Major-General Sir Richard) Westmacott was first employed to attack Saran Sar, which was easily carried, but during the retirement the troops were hard pressed by the enemy, and the casualties numbered sixty-four. On 11th November Saran Sar was again attacked by the brigade of Brigadier-General (afterwards Sir Alfred) Gaselee. Experience enabled better dispositions to be made, and the casualties were only three. The traversing of the valley continued, and on the 13th November Brigadier-General Kempster's brigade visited the Waran valley *viâ* the Tseri Kandao Pass. Little difficulty was experienced during the advance, and several villages were destroyed; but on the 16th, during the return march, the rearguard was hotly engaged all day, and had to be relieved by fresh troops next morning. The casualties numbered seventy-two. Almost daily the Afridis, too wise to risk general engagements, waged a perpetual guerilla warfare, and the various bodies of troops engaged in foraging or survey duties were constantly attacked. On 21st November a brigade under Brigadier-General Westmacott was detached to visit the Rajgul valley. The road was exceedingly difficult, and steady opposition was encountered. The objects were accomplished, and the casualties during the retirement alone numbered twenty-three. The last important work undertaken was the punishment of the Chamkannis-Mamuzais and Massozais. This was carried out by Brigadier-General Gaselee, who joined hands with the Kurram movable column ordered up for the purpose. The Mamuzais and Massozais submitted immediately, but the Chamkannis offered resistance on 1st and 2nd December, the British casualties numbering about thirty. The Kurram column then returned to its camp, and Sir W. Lockhart prepared to evacuate Tirah, despatching his two divisions by separate routes—the 1st under Major-General W. P. Symons (d. 1899) to return *viâ* the Mastura valley, destroying the forts on the way, and to join at Bara, within easy march of Peshawar, the 2nd division under Major-General Yeatman Biggs (d. 1898), and, accompanied by Sir W. Lockhart, to move along the Bara valley. The base was thus to be transferred from Kohat to Peshawar. The return march began on the 9th December. The cold was intense, 21 degrees of frost being registered before leaving Tirah. The movement of the 1st division though arduous was practically unopposed, but the 40 miles to be covered by the 2nd division were contested almost throughout. The actual march down the Bara valley (34 miles) commenced on the 10th, and involved four days of the hardest fighting and marching of the campaign. The road crossed and recrossed the icy stream, while snow, sleet, and rain fell constantly. On the 10th the casualties numbered about twenty. On the 11th some fifty or sixty casualties were recorded among the troops, but many followers were killed or died of exposure, and quantities of stores were lost. On the 12th the column halted for rest. On the 13th the march was resumed in improved weather, though the cold was still severe. The rearguard was heavily engaged, and the casualties numbered about sixty. On the 14th, after further fighting, a junction with the Peshawar column was effected. The 1st division, aided by the Peshawar column, now took possession of the Khyber forts without opposition. Negotiations for peace were then begun with the Afridis, who under the threat of another expedition into Tirah in the spring at length agreed to pay the fines and to surrender the rifles demanded. The expeditionary force was broken up on the 4th April 1898. This

campaign was the greatest since the Indian Mutiny, not excepting the Afghan war of 1878–80. A memorable feature was the presence in the fighting line of the Imperial Service native troops under their own officers, while several of the best known of the Indian princes served gallantly on Sir W. Lockhart's staff.

The total casualties were—

Killed, all ranks	287
Wounded	853
Missing	10
British Officers in addition.	
Killed	23
Wounded	56
Native Officers in addition.	
Killed	4
Wounded	16

besides very many followers. (C. J. B.)

Tiraspol, a district town of Russia, in the government of Kherson, on the left bank of the Dniester, 73 miles by rail north-west of Odessa. It is surrounded by gardens, has a number of steam flour-mills and tobacco factories, and carries on a considerable trade with Rumania. Population (1897), 27,585.

Tireh, the ancient *Teira*, a town of Asia Minor, situated in the valley of the Kuchuk Mendere (*Caystrus*) at the foot of Mount Messogis. It is connected with Smyrna by railway, and has a trade in raisins, wheat, rice, tobacco, and cotton. The population consists of 8000 Moslems and 6000 Christians.

Tirnovo (Bulgarian, *Trnovo*), the chief town of a department, Bulgaria, on the Jantra, an affluent of the Sistova, on the Sofia–Varna railway, at the junction of the branch line from Rustchuk, 124 miles E.N.E. of Sofia. The town consists of two divisions—the Christian quarter, situated chiefly on a high rocky plateau, and the Turkish quarter, on the lower ground. On the Tsarevetz Hill above the town are the remains of the ancient fortress. The Husardjaini mosque is now used as a military powder and dynamite factory. In the old Christian quarter there are some interesting churches of the Middle Ages. Numerous antiquarian remains have also been discovered. There are a gymnasium and a high-class girls' school. The town possesses large dye-works, and important manufactures of copper utensils.

Tirnovo was the ancient capital of Bulgaria, and from 1186 until its capture by the Turks, 17th July 1394, the residence of the Bulgarian Tsars of the house of Aiden. From the beginning of the 13th century it was also the seat of the patriarchate of Bulgaria, until the suppression of the patriarchate in 1767. In 1877 it was taken from Turkey by the Russians, and in 1879 Alexander of Battenberg was there elected Prince of Bulgaria. Population (1892), 12,858.

Tirol, a province of the Austrian Empire. It may be roughly described as the mountainous region intervening between Munich and Verona, so that, owing to the Brenner Pass connecting those two cities, Tirol has always been of extreme military importance. It comprises all the highest summits of the Austrian Alps, which culminate in the Ortlerspitze (12,802 feet). The German-speaking north and central Tirol are sharply distinguished in many respects from the Italian-speaking south Tirol, the latter including the now well-known group of Dolomite mountains. North Tirol sends its waters to the Black Sea, while those of south Tirol flow to the Adriatic. The area of Tirol (excluding Vorarlberg, often counted with it) is 10,300 square miles, of which about 4000 square miles are covered by forests. In 1890 the total population was 812,696, and in 1900, 850,062. The inhabitants are mostly Roman Catholic. More than one-half are German-speaking, and of the remainder the vast majority speak either Italian or the ancient and curious Ladin dialect. From an administrative point of view Tirol forms twenty-one districts (*Bezirke*). Its capital and largest town is Innsbruck. The other most important towns are Trent (24,908 in 1900), Bozen (13,632), and Rovereto (10,180).

The mountain pastures ("Almen") are less carefully looked after than those in Switzerland, one reason being that they often belong not to the neighbouring villages, but to far-distant places, so that those who in Switzerland would be their owners are helpless. The vine-growing area is about 40,500 acres (of which 26,750 acres are in south Tirol), of which the mean annual produce may be put at 8,360,000 gallons. The silk industry has fluctuated greatly, rising from 1,400,000 kilogrammes in 1881 to 2,150,000 kilogrammes in 1888, but falling in 1890 to 1½ million kilogrammes.

Tirupati, or Tripetty, a town of British India, in the North Arcot district of Madras, 84 miles north-east of Madras, with a station on the Madras Railway. Population (1891), 14,238; municipal income (1897–98), Rs.1,84,840. It is famous for a pagoda or temple on a neighbouring hill, 2500 feet above the sea, which is one of the most frequented places of pilgrimage in southern India. Two high schools are maintained, one by a German mission, the other by the high priest of the temple.

Tisserand, François Félix (1845–1896), French astronomer, was born at Nuits-Saint-Georges, Côte-d'Or, on the 13th January 1845. In 1863 he entered the École Normale Supérieure, where his remarkable talents were soon recognized, and on leaving he went for a month as professor at the lycée at Metz. Le Verrier, however, who had formed a just estimate of his abilities, offered him a post in the Paris Observatory, which he accordingly entered as *astronome adjoint* in September 1866. In 1868 he took his doctor's degree with a brilliant thesis on Delaunay's Method, which he showed to be of much wider scope than had been contemplated by its inventor. Shortly afterwards he went out to Malacca to observe the famous solar eclipse of 18th August 1868. In 1873 he was appointed director of the observatory at Toulouse, whence he published his *Recueil d'exercices sur le Calcul infinitésimal*, and in 1874 became corresponding member of the Académie des Sciences. He took part in the French expeditions of 1874 to Japan and of 1882 to Martinique to observe the transits of Venus. In 1878 he was elected a member of the Académie des Sciences in succession to Le Verrier, and became a member of the Bureau des Longitudes. In the same year he was appointed *professeur suppléant* to Liouville, and in 1883 he succeeded Puiseux in the chair of celestial mechanics at the Sorbonne. In the midst of so many occupations Tisserand always found time to continue his important researches in mathematical astronomy, and the pages of the *Comptes Rendus* bear witness to his

surprising activity. His writings relate to almost every branch of celestial mechanics, and are always distinguished by rigour and simplicity in the solution of the most difficult problems, and by a clearness and elegance peculiarly French. He treated in a masterly manner (*Bulletin Astronomique*, 1889) the theory of the capture of comets by the larger planets, and in this connexion published his valuable *Criterion* for establishing the identity of a periodic comet, whatever may have been the perturbations brought about in its orbit, between successive appearances, by the action of a planet. His principal work, *Traité de Mécanique céleste*, is the noblest and most lasting monument to his memory, and is worthy to stand beside the *Mécanique céleste* of his fellow-countryman, Laplace. In this treatise, published in four quarto volumes, the last of which appeared only a few months before his death, he fused into one harmonious whole the researches of Laplace and those of other workers in the same field since his time. It furnishes a faithful and complete *résumé* of the state of knowledge in that department of astronomy at the end, as Laplace's great work did for the beginning, of the 19th century. In 1892 he succeeded Mouchez as director of the Paris Observatory, and as president of the committee of the photographic chart of the heavens he contributed largely to the success of that great project. Under his direction the revision of Lalande's catalogue was brought almost to completion, and four volumes of the *Annales de l'Observatoire de Paris* exhibit the progress made in this important undertaking. He was also editor of the *Bulletin Astronomique* from the beginning, and contributed many important articles to its pages. He died suddenly, in the fulness of his power, of congestion of the brain, on 20th October 1896. (A. A. R.)

Tissot, James Joseph Jacques (1836–1902), French painter, was born at Nantes on 15th October 1836. He studied at the École des Beaux Arts in Paris under Ingres, Flandrin, and Lamothe, and exhibited in the Salon for the first time at the age of twenty-three. In 1861 he showed "The Meeting of Faust and Marguerite," which was purchased by the State for the Luxembourg Gallery. At this period he was a follower of the classical tradition, a careful draughtsman with a sense of composition but no particular originality of idea. His first characteristic period made him a painter of the charms of women. His models were of the worldly type—*demi-mondaine* would be more strictly accurate as a description of the series of studies which he called "La Femme à Paris." He fought in the Franco-German war, and then, falling under suspicion as a Communist, he left Paris for London. Here he studied etching with Sir Seymour Haden, drew caricatures of public men for *Vanity Fair*, and painted portraits as well as *genre* subjects. It was many years before he turned to the chief labour of his career—the production of a series of 700 water-colour drawings to illustrate the life of Christ and the Old Testament. Some sudden shock or bereavement was said to have turned his thoughts from ideals of the café and the boulevard into a more serious channel. He disappeared from Paris, whither he had returned after a stay of some years in England, and went to Palestine to begin the task which occupied him during the rest of his life. In 1895 the series of 350 drawings of incidents in the life of Christ was exhibited in Paris, and the following year found them on show in London. They were then published by the firm of Lemercier in Paris, who had paid him 1,100,000 francs for them. After this he turned to the scenes of the Old Testament, upon which he was still engaged at the abbey of Buillon, in the department of Doubs, France, when he died on 8th August 1902. The merits of Tissot's Bible illustrations lay rather in their imaginative power and in the care with which he studied the details of scenery than in any quality of religious emotion. He seemed to aim, above all, at accuracy, and, in his figures, at a vivid realism which was far removed from the conventional treatment of sacred types. His achievement called forth admiration for his genius, but it was the genius that is an infinite capacity for taking pains, not the genius of insight and inspiration that is found in the greatest art.

Tisza, Koloman von (1830–1902), Hungarian statesman, was sprung from a noble Hungarian family whose estates were situated in the county of Bihar, and was born at Geszt on the 16th of December 1830. After studying law, in the year 1848 he received an appointment in the ministry of education under Baron Eotvos. He took no part in the revolution, retired from the public service, and for some years lived in seclusion on his estates. He first came prominently before the public notice in 1859. In this year he took the leading part in the agitation which was aroused by the attempt of the Government to interfere in the autonomy of the Hungarian Protestant Church. In 1861 he was elected a member and first vice-president of the new Diet, and from this time was leader of the Left Centre in the Lower House. While he was opposed to the demands of the extreme Kossuth and Republican party, he was not always prepared to accept all Deák's proposals for arranging a compromise with the emperor. The differences were however small, and in the crisis of 1865–66 he and his followers worked in close harmony with Deák. He was a loyal supporter of the *Ausgleich*, in the discussions on which he had taken a large part. He had also made himself known as a supporter of free trade and other Liberal reforms, which he advocated in the press. After 1866 he was for many years leader of the parliamentary Opposition to the administration of Andrassy. After several times refusing office, he accepted the post of minister of the interior in 1875, and in the end of the same year became president of the ministry. This post he held till the year 1890. For a history of his administration the reader is referred to the article on Hungary. The strong measures which he took to further Magyar nationality in the German and Slavonic districts won him great popularity among his own countrymen, and enabled him to surmount the crisis caused by the occupation of Bosnia. In foreign policy he took little interest, but he was successful in the financial administration, and did much to develop the material resources of the country. From 1887 to 1889 he was minister of finance. He resigned in March 1890 and died on 23rd March 1902. His brother Ludwig (born 1832) held many important posts in the internal administration, and on two occasions, from 1871 to 1873 and from 1892 to 1894, was a member of the ministry. He received the title of count in 1883. This title descended to Stephan, the eldest son of Koloman, who became leader of the Liberal party in the Lower House of the Hungarian Parliament.

Titan Cranes.—Probably no branch of engineering has developed more rapidly of recent years than that which is concerned with the design and construction of harbours. Breakwaters were in earlier days generally constructed of masonry walls or of plain "rubble mounds," *i.e.*, of heaps of rough large stones thrown into the sea and left to be consolidated by the action of the waves. But, owing to the increased depth of water and the more exposed sites in which they are now built, new methods have gradually been evolved. Amongst the most noteworthy

has been the employment of Portland cement, from which are made artificial blocks of stone that have many advantages over the natural blocks previously used. Breakwaters are now mostly built up of such concrete blocks, either directly from the bottom, or on a low rubble mound foundation, the top of which is kept such a distance below the surface as to be out of the reach of the greatest wave action. The blocks are generally of very large size, seldom weighing less than 10 tons, and often as much as 40 or 50 tons or even more.

The typical method of block-setting formerly was to construct over the whole extent of the site a timber staging, resting on heavy piles driven into the bed of the sea; this staging supported lines of railway placed at a very wide gauge apart, and on the rails ran "travellers," spanning the whole width of the breakwater. The traveller beams carried other rails placed at right angles to the former, and these carried in their turn a powerful lifting crab, which could be traversed across from side to side. The whole machine could be moved forward on the staging as the work proceeded, and thus the whole area within the lines of staging could be perfectly commanded for the purpose of block-setting. The concrete blocks were brought from the land along "service roads" laid along the staging; when they came under the travellers they were lifted by the crab off the railway truck, and after being travelled and traversed to the correct position were lowered to the divers, who saw that they were accurately placed in their final situation. Within wide limits this method was an exceedingly convenient one, and it is still largely made use of for certain situations, with of course the improvement of substituting steam or other motive power for hand. Certain difficulties, however, arise with the stagings, especially in exposed sites, for they are very expensive to construct, and very liable to damage from storms. In every breakwater there must of necessity be during the period of construction an unfinished or so-called "scar end," which, with the staging around and in front of it, is particularly liable to damage by the sea, more especially in those works which can only be carried on during a fine season and have to be left during the winter in an unfinished state exposed to heavy storms. A single winter storm has often done enormous injury by washing away the greater portion of the staging and the plant carried on it, thus involving the expenditure of very large sums for restoration and the loss of much working time. In view of these facts, it gradually came to be recognized that instead of relying on a temporary staging placed in the most exposed situation for the support of the block-setting machinery, it was quite possible to utilize the finished work itself; and this idea, coupled with the further one of making the whole block-setting plant self-contained and portable, resulted in the introduction of the "Block-setting Titan" of the present day.

All the early Titans were what may be called "rectangular" or "non-revolving" machines, in distinction to the later "revolving" machines. They consist essentially of a portable structure which travels on wheels running on rails laid at a very wide gauge on the surface of the completed portion of the work, this substructure or carriage being sufficiently raised in the centre of its breadth to leave a clear passage-way beneath it for the trucks with concrete blocks to pass right up to the end of the work. The upper part of the carriage is extended forwards in the form of two great projecting arms or cantilever girders, which reach out over the water and carry a travelling crane of similar construction to those previously used on the timber staging. The traveller is worked by a steam engine and boiler placed at the rear end. At the back of the machine is also placed the counterpoise required to balance the weight of the concrete block and of the traveller when they are run out over the water; for this counterpoise a large tank filled with sea-water has often been used, though latterly blocks of concrete are more usually adopted. The driving engine is so designed that it can be disengaged from the shafting which actuates the traveller, and coupled to the mechanism which propels the Titan along the rails laid on the breakwater. The operation of the Titan is very simple. The block is lifted in the blockyard on to a truck, and run down the railway until it comes within reach of the traveller. It is then raised just sufficiently to free it from the truck and travelled forwards over the water, into which it is lowered in order that the partial buoyancy of the water may relieve the Titan of a portion of the overhanging weight. The next operation is to travel it farther forward or traverse it to either side as far as may be necessary to bring it exactly over the position where it is desired to set it, and finally it is lowered until it takes a bearing on the rubble mound or on the blocks which were laid before it. All these operations are controlled by signals received from the divers who are working below the surface. When a sufficient length has emerged above high-water mark the railway is lengthened and the Titan moved forward to construct another section.

It will thus be seen that the essential features of this type of Titans are powerful lifting machinery, the capacity of running out heavy weights over the water horizontally, and portability. But while they proved very successful and useful pieces of plant, and may still be efficiently employed in places where the water is not too deep and the section of wall is suitable, they have several disadvantages or limitations. Their overhang is comparatively short, and is further reduced to a certain extent by the necessity of leaving sufficient space at the front end for the truck carrying the blocks to get within reach of the lifting gear. A still more serious objection is that they are quite unable to deal with material which, as is very often the case, has to be placed outside the line of rails on which they run. It seems to us now very simple to suggest that the whole upper part of the Titan should be made to revolve round a centre pivot, but curiously enough the machine underwent a whole series of intermediate stages before it settled down to its present form, all of which were dictated by the primary object of setting blocks outside the normal range. Special "side-setting machines" were designed with the overhanging members placed at right angles to the pier instead of parallel to it; these followed behind the main machine, to put in the side blocks after the principal work was done. Titans were also constructed which could be twisted round bodily, the railway wheels being made to swivel like castors. Others had a superstructure which was connected to the under-carriage at the back end by a fixed pivot, and rested at the front on rollers running on a "roller path" of segmental shape; these machines could be radiated through an arc of a circle sufficiently great to enable the requisite range sideways to be attained. The final step was the very obvious one of placing the pivot in the centre of the truck, and extending the roller path until it formed a complete circle, thus producing a Titan that could be turned right round.

Local circumstances may still sometimes justify the choice of any of these types, but nearly all the later machines are made to revolve through a complete circle. This has proved to be of great practical advantage. In many cases, the breakwater to be constructed being a detached work without any connexion with the land, it is necessary to bring the blocks up to the work in barges. From these barges the revolving Titan, working simply as a huge crane, is able to lift the blocks and stack them on the pier at the back of the machine until wanted—an operation quite impossible with a non-revolving machine. Even when the blocks are brought forward on trucks the revolving Titan can pick them off the truck when placed in its rear, and is thus, as previously indicated, enabled to stand nearer the end. In this way the available overhang is increased, and with the completely revolving machine the blocks can be set as far out at each side as in front. In addition, certain structural advantages are gained by the adoption of the revolving type; *e.g.*, considerably greater overhang with a given weight of machine. This question of overhang is one of paramount importance to the designer both of the breakwater and of the Titan. In a regularly built breakwater in course of construction, the lowest layer of blocks is always the longest, and the last cross row in this layer forms the bottom step of a great flight which rises step by step until it reaches the surface, where the top step consists of the cross row of blocks forming for the time being the end of the surface layer. Now, the deeper the water, the greater the number of steps and the greater the distance of the bottom step in advance of the top one; and it is this distance which practically settles the required overhang, though it is also to a considerable extent affected by the way in which the blocks break joint or are bonded together, and by the size of the blocks. In a pier built with a sloping bond the tiers of blocks break joint on lines placed more nearly upright than horizontal (about 60° is a usual angle), and this gives for obvious reasons a much shorter scar end, and one well suited for setting by the older type of Titan with short overhang. Taking all these points into consideration, it has been found necessary gradually to increase the overhang beyond that which was practicable with the older type. In the revolving machines the dimension which determines the overhang is the "radius," or the horizontal distance from the centre pivot to the

load when travelled outwards as far as it will go. A very usual radius for an average size of Titan is now about 75 feet, but radii are found in the largest machines ranging up to as much as 100 feet. Even those not conversant with engineering matters will appreciate the enormous size and power of a machine that will pick up a block weighing 50 or 60 tons and swing it round in a circle 200 feet in diameter.

The modern Titan therefore consists of a high truck running on a wide railway and carrying on its upper side a great circular turntable and a centre pin around which revolves a massive superstructure. The essential features of the revolving upper part are the long horizontal arm on which the load is run out, and the platform carrying the lifting machinery, engines and boiler, and also at the rear end the concrete ballast. There are two methods of supporting the horizontal arm: one is to construct it in the form of two stiff cantilever girders, either built up of solid plates

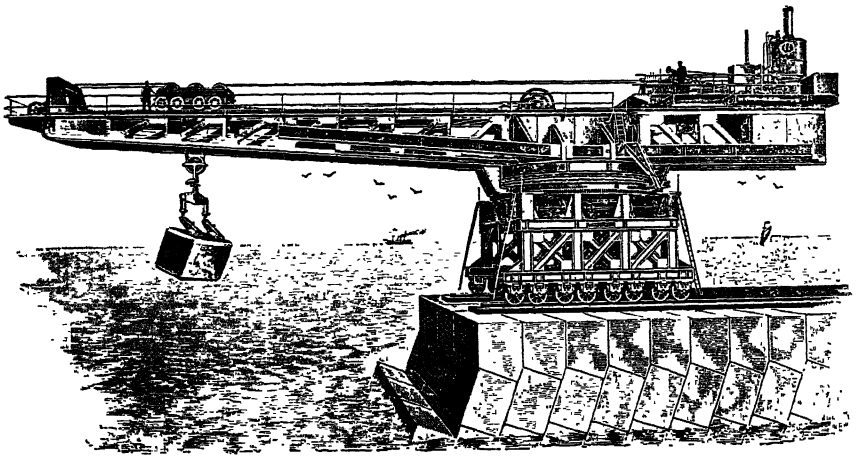

FIG. 1.—36-ton Block-setting Titan Crane.

of steel or of openwork lattice bracing; and the other to erect on the superstructure a so-called "king-post," and to support the arm or "jib" by tension rods in a somewhat similar manner to the rods of a suspension bridge. The former are known as "cantilever" machines, and the latter as "overhead trussed" machines. Which of these two types should be adopted in any given case is, in the writer's opinion, very much a matter of fashion or individual preference; but, speaking generally, it may be said that for loads over 40 tons combined with a radius of over 75 feet the cantilever type would now be the one more generally adopted. Fig. 1 illustrates the method of working with a Titan setting blocks with inclined bond as described above, and Fig. 2 (see Plate) shows a similar machine setting apron blocks at right angles to the line of the breakwater at South Shields. Fig. 3 (see Plate) shows one of the two large cantilever machines built by Messrs Stothert and Pitt of Bath, used for the Admiralty harbour works at Gibraltar. As will be seen, they are of the cantilever type, with open lattice-work jib; they can set blocks weighing 36 tons at a maximum radius of 75 feet. The concrete block is suspended by wire ropes from a trolley which can be moved in or out along the horizontal jib; the ends of the lifting rope are attached to a large revolving barrel which can be set in motion by the engines, lowering out being effected by the weight of the block itself and the descent controlled by Matthew's hydraulic brakes, which absorb the work given out in lowering by forcing water through a narrow orifice. The illustration also shows the large circular rings with the rollers between them on which the whole upper part revolves, the turning motion being given by a steel pinion which gears into a circular fixed toothed ring attached to the lower roller path. For the travelling movement along the breakwater there is a shaft which passes down through the centre pin and communicates motion to the wheels on which the Titan runs. The large box or tank under the boiler contains the necessary concrete ballast, and it will be seen that the engines, boiler, and machinery are placed as far back as they conveniently can be, in order to assist the balance and to get a long straight pull for the wire ropes. The lower wheels are fitted with springs, to allow for inequalities of the railway. The breakwater at Gibraltar is a detached work, which was commenced by floating out a large steel caisson and sinking it until it rested on a rubble mound. It was then filled with concrete so as to form an enormous monolith of artificial stone, on which the first Titan was erected and employed to lay blocks until a sufficient length of wall was built for it to be moved forward to make room for the erection of the second machine. The two were then set back to back, the distance between them being gradually increased as the work proceeded. For a further description of the breakwaters and other naval works at Gibraltar the reader is referred to the article on DOCKYARDS.

The introduction of these Titans has been of enormous service to the harbour engineer. They have enabled harbours to be built in difficult situations at much less cost than by previous methods and in much less time, while a special advantage is the facility with which they can be brought up to the work and removed again, since in this way short spells of fine weather can be utilized and the risk of loss is reduced to a minimum. In many works it is a regular rule to run the setting plant back to a safe place and anchor it fast every evening after the day's work is done; and that this is not an unnecessary precaution will be seen when it is remarked that in several instances Titans have been carried along the rails by the force of the wind and the waves and lost over the end or washed bodily into the sea.

The huge blocks which are placed in position in the sea by the Titan require elaborate machinery for their preparation. The concrete has to be mixed out of sand, shingle, and cement, then placed in the moulds and allowed to set; when sufficiently firm to permit of being removed, the blocks have to be stacked in the blockyard until seasoned for use, and finally they have to be lifted on to the heavy railway trucks which convey them to the Titan. All these operations involve the use of specially designed plant, among which may be mentioned particularly the great Goliath cranes which span the blockyard and handle the blocks.

Little has been written on the special subject of the Titan, but a few descriptions of single machines may be found in the files of the *Engineer* and *Engineering*, and a general *résumé* in Pitt's paper "On Plant for Harbour and Sea-Works," *Proc. Inst. C.E.*, vol. cxiii. (W. P*.)

Tithes (ENGLAND AND WALES).—The payment of tithes, or the tenth part of the produce of lands, and in some cases of the profits of labour, towards the maintenance of the beneficed clergy, has been known to English law since the 8th century, and was certainly established before the Norman Conquest. A full discussion of their origin and history is to be found in Lord Selborne's *Ancient Facts and Fictions concerning Churches and Tithes*, and the *History of the Law of Tithes in England*, by G. Edwardes Jones.

In present circumstances, the subject is perhaps best dealt with in two chronological divisions—tithes under the system existing previously to the Commutation Acts, and tithes under the system then introduced.

Before the Commutation Acts.

I. Whether or not, as it is said, before the Council of Lateran in 1180, a man could have given his tithes to any church or monastery that he pleased, at any rate since that time, with the division of dioceses into parishes, they now of common right belong to the church within whose parish they arise, although by prescription they may belong elsewhere. The general rule was said to be that all lands within a parish are subject to tithes, and a layman was not allowed to prescribe generally that his lands were exempt; but he had to show a special exemption, and no length of possession was regarded in law in view of the maxim *nullum tempus occurrit ecclesiæ*, although equity did take account of it. The tithes in places extra-parochial, *e.g.*, forest lands, belong to the Crown, although by canon law they were to be disposed of by the bishop; but by custom a parson or vicar might be entitled to them. The tithes of tithable cattle pasturing in any waste or common ground whereof the parish is not certainly known, were made

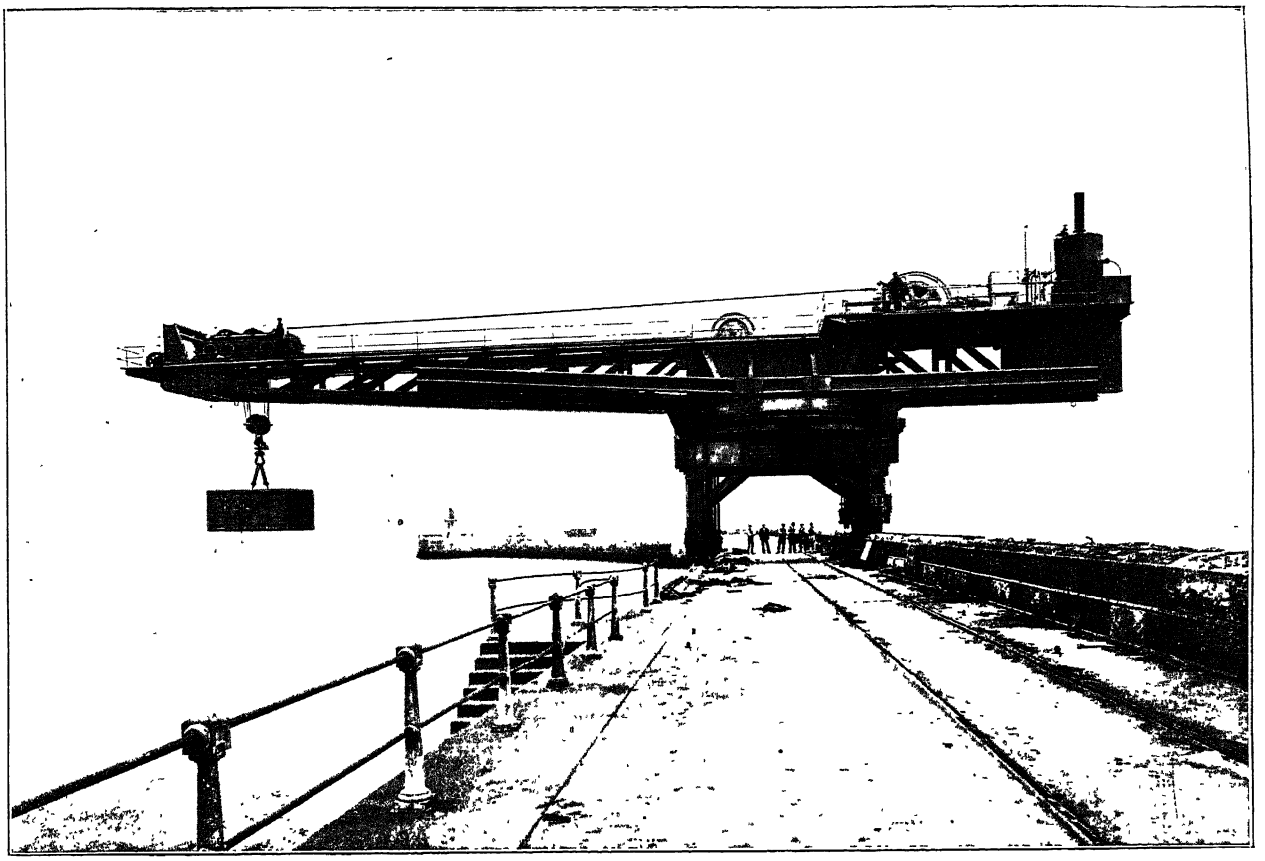

FIG. 2.—Titan Crane setting Apron Blocks at the Breakwater at South Shields.

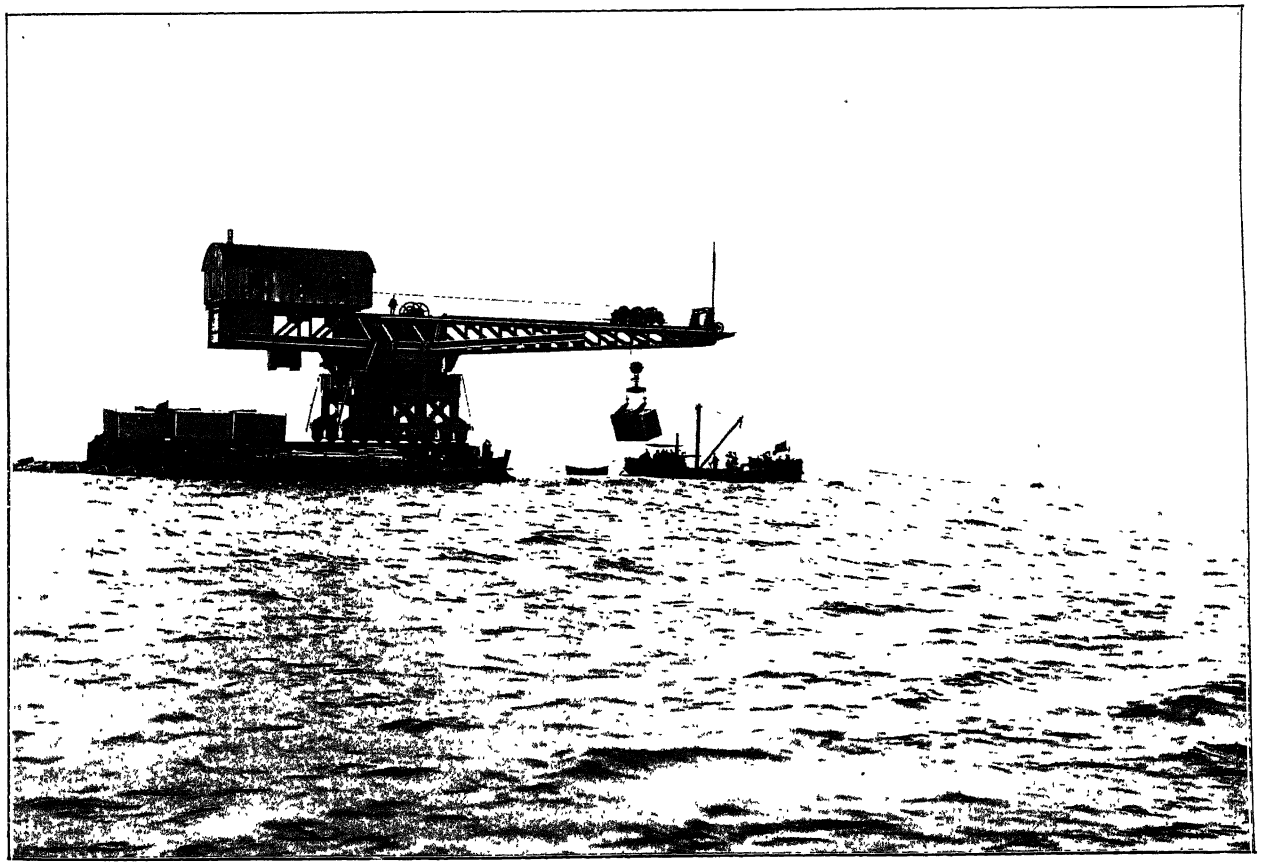

FIG. 3.—Cantilever Type of Titan Crane used for the British Admiralty Harbour Works at Gibraltar.

payable to the parson of the parish where the cattle dwell, by a statute of Edward VI.

Tithes were classified according to their nature as prædial, or arising immediately from the ground, *e.g.*, grain of all sorts, hay, wood, and the like; mixed, or arising from things immediately nourished by the ground, *e.g.*, colts, lambs, eggs, and the like; or personal, namely, of profits arising from the honest labour and industry of man, and being the tenth part of the clear gain, *e.g.*, fishing, mills, and the like; or according to value, as great, *e.g.*, corn, hay, and wood; or little, which embraced all others. Of common right tithes were only payable of such things as yield a yearly increase by the act of God, and generally only once a year. They were not payable of the following, except by custom: things of the substance of the earth, such as coals, minerals, turf, and the like; things *ferœ naturœ*, such as fish, deer, and the like; things tame, such as fowls, hounds, or fish kept for pleasure or curiosity; barren land, until it is converted into arable or meadow land, and has been so for seven years; forest land, if in the hands of the king or his lessee, unless disafforested; a park which is disparked; or glebe land in the hands of the parson or vicar, which was mutually exempted from payment by the one to the other, but not if in the hands of the vicar's lessee. Another exception to the incidence of tithes were abbey lands. These were exempted generally by Pope Pascal II. while in the hands of their owners, but the privilege was restricted by Pope Adrian IV. in the time of Henry II. to the three religious orders of Cistercians, Templars, and Hospitallers (to whom the Templars' lands were given on their dissolution in 17 Edw. II.), to which Pope Innocent III. added the Præmonstratenses. The Council of the Lateran in 1215 further restricted this exemption to lands of which these orders were in possession before that Council. A custom by the religious to obtain exemption for lands let to their tenants by means of bulls from the Pope was put an end to by a statute of Henry IV. making the acquisition or use of such bulls henceforward a *præmunire*. When the religious houses were dissolved by Henry VIII., in the case of the greater abbeys and priories the exemptions from payment of tithes enjoyed by them passed to the Crown or the persons to whom the Crown assigned them, and thus any lands which might have been thus exempted, whether they had been actually so or not, were presumed to be exempt; and a further exemption was created by parsonages coming into the same hands as tithable lands, which lasted so long as such union continued.

A further exemption from tithes was given by an Act of 1832 (2 & 3 Will. IV. 100), which fixed a period of prescription against claims of tithe by laymen or corporations aggregate, of thirty years during which there had been no payment of tithes or a *modus* or composition had existed, in the absence of contrary evidence, and in any case of sixty years; and against corporations sole, of sixty years or the tenures of two successive incumbents and three years after the entry of a third. The tithes which came into lay hands by the dissolution of the religious houses and the previous suppression of alien priories by Henry V. became in all respects incorporeal freehold property. Under the Limitation Act of 1833 twenty years of adverse possession of an estate in tithes gave a good title, except as against spiritual or eleemosynary corporations sole whose right to recover tithes was limited if at all to a period of two incumbencies and six years afterwards, or sixty years (§ 29).

Tithes were generally recovered by a writ against the owner of the tithable property usually brought in the ecclesiastical courts (questions of title to tithes being reserved to the temporal courts), the jurisdiction of which in this respect was confirmed by the statutes *Circumspecte agatis* (13 Edw. I.), *Articuli Cleri* (9 Edw. II.), and others of Henry VIII. and Edward VI., and was enforced by ecclesiastical censures and the writ *de excommunicato capiendo*; and an Act 2 & 3 Edw. VI. made any person refusing to set out tithes liable to pay double the value in the ecclesiastical court or treble in a common law court. Tithes of small amount or due from Quakers could be recovered by summary proceedings before justices under statutes ranging from William III. to Victoria. Tithes could also be sued for in equity, especially the equity side of the Exchequer. A custom also sprang up, and was common at the time of the Commutation Acts, for a tithe-owner to accept a fixed sum of money or fixed quantity of the goods tithable in place of the actual tithes, known as a *modus decimandi*, whether in respect of a whole parish or only of particular lands within it; and this could be sued for in the ecclesiastical courts. Tithe-payers could also file bills in equity to establish a *modus* against a tithe-owner. In the City of London there were customary tithes; in other towns and places there were compositions for tithes which were confirmed by local Acts of Parliament; and according to a return presented to the House of Commons in 1831, there were passed between 1757 and 1830 no less than 2000 local Acts containing clauses for the commutation of tithes. Enclosure Acts often gave a portion of the lands enclosed to the spiritual or lay rector, and exempted the rest from tithes; and in other local Acts a corn rent or yearly money payment was substituted for tithes. Except, however, where made under parliamentary authority, no composition for tithes, although made between the landowner and the parson or vicar with the consent of the patron and ordinary, bound a succeeding incumbent, the statute 13 Eliz. 10 prohibiting any parson or vicar from making any conveyance of (*inter alia*) tithes, being parcel of the possessions of their churches, to any persons, except leases for twenty-one years or three lives.

II. The principle of the Tithe Commutation Acts (1836–1860) is to make permanent and general the system which had been only partial or temporary (in most cases), and to "substitute a corn rent (known as a tithe rent charge), permanent in quantity and payable in money, but fluctuating in value, for all tithes, whether payable under a *modus* or composition or not, which may have heretofore belonged either to ecclesiastical or lay persons" (Phillimore, *Eccles. Law*, ii. 1161).

After the Commutation Acts.

Commissioners (now the Board of Agriculture) are appointed to execute the Acts; a rent charge on all lands liable to tithes at the time of the passing of the first Act is substituted for those tithes, of which the gross amount is ascertained either by voluntary parochial agreement, or, failing that, by compulsory award confirmed by the Commissioners; and the value of the tithes is fixed in the latter case by their average value in the particular parish during the seven years preceding Christmas 1835, without deduction for parochial or county and other rates, charges, and assessments falling on tithes, the rent charge being liable to all the charges to which tithes were liable. The rent charge is apportioned on all the lands liable in the parish, and such apportionment may be altered or a new one made: and the value of the rent charge is fixed at the value (at the time of confirmation of the apportionment) of the number of imperial bushels and decimal parts of bushels of wheat, barley, and oats as the same would have purchased at the prices so ascertained by the advertisement (of prices of corn) to be published immediately after the passing of the Act 6 & 7 Will. IV. 71, in case one-third part of such rent charge had been invested in the purchase of wheat, one-third part in the purchase of barley, and the remaining third part in the purchase of oats; and the respective quantities of wheat, barley, and oats so ascertained shall be stated in the draft of every apportionment. The price at which the conversion from money into corn is to be made at the time of confirmation of such apportionment, according to the provisions of the said Act, are 7s. 0½d. for a bushel of wheat, 3s. 11½d for a bushel of barley, and 2s. 9d. for a bushel of oats (7 Will. IV.

and 1 Vict. 69); the average price of the bushel of each grain is now computed by substituting for the "advertisement" above the statement of the septennial average price of the imperial bushel of British corn made under the Corn Returns Act, 1882; and thus the value of the statutory amount of corn is now fixed for each year at the beginning thereof at the average price of the three components of corn for the previous seven years. The extent of the depreciation in value of tithe may be gathered from the fact that for 1902 the price of the wheat bushel is thus fixed at 3s. 5¼d., that of the barley bushel at 3s. 0½d., and that of the oats bushel at 2s. 1d.

As already indicated above, certain lands are exempt from payment of tithes while in the occupation of their owners, either by reason of their having been parcel of the possessions of any privileged order, or by reason of their being of the tenure of ancient demesne and exempt whilst in the tenure, occupation, or manurance of the Crown, its tenants, farmers, and lessees, or under-tenants although they are subject to tithes when aliened or occupied by subjects not being such; and in these and in all such cases, with the consent of such owners, a fixed rent charge may be substituted for any contingent rent charge imposed on them (2 & 3 Vict. 62; 3 & 4 Vict. 15, now repealed except as to tithes not commuted). In certain cases where commutation of tithes for rent charge in the ordinary way was impracticable, *e.g.*, in the case of Lammas lands or in the case of common lands, power was given to charge a fixed sum or rate per head of the cattle there pasturing, with an exception in the case of Lammas lands which for seven years before Christmas 1835 had paid no tithe; and also to fix a rent charge in respect of tithes of common appurtenant on the allotment made in respect of the lands to which such right of common attached (2 & 3 Vict. 62; 3 & 4 Vict. 15; 9 & 10 Vict. 73). By an Act of 1860 (23 & 24 Vict. 93) a gross rent charge can be substituted for a commutation of tithes on common rights at a fixed sum per head; a gross rent charge made payable in respect of the tithes of a gated or stinted pasture rated to the relief of the poor may be apportioned thereupon and enforced in the method prescribed by the other Tithe Acts; a rent charge on commons may be commuted for part of the land or redeemed, if the landowners and persons liable for tithe so agree; and upon enclosure, a rate per head may be converted into a rent charge on the lands allotted. These rent charges are not subject to the Tithe Act of 1891. This Act of 1860 also gave power to convert the corn rents established under local Acts into rent charges.

In the case of hop-grounds, orchards, fruit-plantations, and gardens, power was given to the Commissioners to value them separately, according to the average rate of composition for the seven years preceding Christmas 1835, and to fix an ordinary and an extraordinary charge for tithes thereof, the former for such lands going out of cultivation, the latter for such as were thereafter newly cultivated: lands subject to the latter were exempted during their first years of cultivation; and such lands were only subject to it if situated in a parish in which an extraordinary charge had been distinguished at the time of commutation (6 & 7 Will. IV. 71; 2 & 3 Vict. 62; 3 & 4 Vict. 15; 23 & 24 Vict. 93; 36 & 37 Vict. 42). In 1886, however, it was enacted that no such extraordinary charge shall be levied on any such grounds so newly cultivated in future; the capital value of the existing charges was assessed, and the payment of interest thereon was made a rent charge on the land payable in priority to all other charges until its redemption, and recoverable in the same way as ordinary rent charge and exempt from all rates, charges, and assessments: the charge was redeemable at the capital value, and saving existing contracts it was as between landlord and tenant payable by the landlord, any agreement to the contrary notwithstanding; and it is not subject to the Tithe Act of 1891. Under the Act of 1840 (3 & 4 Vict. 15) gardens and lawns and the like, of small size, could be exempted from tithes.

Besides the tithes dealt with by local Acts as already mentioned, certain other kinds of tithes are outside the scope of the Commutation Acts, namely, tithes of fish and fishing, personal tithes other than tithes of mills, and mineral tithes, unless the landowners and tithe-owners consent to make a parochial agreement for commutation before the confirmation of an apportionment after a compulsory award in such parish. As already seen, fish being *ferœ naturæ* are only tithable by custom; but fish taken in the sea by the custom of the realm are tithable as a personal tithe, *i.e.*, in some small sum for the net profits of the fishing, and customs for payment in kind have been upheld by the courts. Personal tithes, if not commuted or otherwise still payable, are regulated by a statute of Edward VI., which (except in the case of fishing and tithes for houses in cities and towns, which may be due by custom) restricted them to such persons exercising merchandises, bargaining and selling clothing, handicraft or other art or faculty in such places as had for forty years previously so used to do. Personal tithes are now rare, except of fish caught at sea, when they are payable to the church where the taker hears divine service and receives the sacraments. Tithes on houses or customary payments in lieu of tithes have, by local Acts, in some cases been turned into church rates. Statutory provision is also made for allowing tithes and tithe rent charge to be exchanged for land, and for the redemption of rent charges made under the Acts, and also of corn rents under the local Acts. Tithe rent charge may also be merged in the land tithable, with the consent of the Tithe Commissioners and the landowner, by the legal and equitable owners of tithes in fee simple or fee tail, or persons having power to appoint the fee simple in tithes, or owners of glebes, or owners of lands and tithes settled to the same uses.

Tithe rent charge under these Acts is subject to the same liabilities and incidents as tithes, such as parliamentary, parochial, county, and other rates, especially the poor rate and highway rate; but the owner of tithe rent charge attached to a benefice has been exempted by an Act of 1899 from payment of half the amount of any rate which he would be liable to pay under the Agricultural Rates Act, 1896, the other half being borne by the Inland Revenue Commissioners. The limitation of time for recovery of tithes or estates in tithes, whether between rival claimants to tithes or tithe-owners or tithe-payers, if belonging to lay individuals or lay or spiritual corporations aggregate, is a period of twelve years, as in the case of other real property (37 & 38 Vict. 57); and in the case of spiritual corporations sole the period of limitation of actions, if any, is governed by the Limitation Act, 1833, § 29, already quoted, the Act 2 & 3 Will. IV. 100 being held only to apply to demands of tithe in kind.

The method of recovering rent charge under the Commutation Acts was distraint where the rent charge is in arrear for twenty-one days after the half-yearly days of payment, and entry and possession with power of letting if it is in arrear for forty days, and arrears for two years are so recoverable: this power of distress and entry extends to all lands occupied by the occupier of the land whose tithe is in arrear as owner or under the same landlord; but no action lies against the owner or occupier of the land personally. If a tenant quits leaving tithe unpaid, the landlord may pay it and recover it from him. The tithe-owner cannot recover damages from the tithe-payer for not cultivating the land. Special provision is made for the recovery of the rent charge in railway lands.

The Act of 1891 has, however, altered this method of recovering tithes, and substituted another intended to shift the burden of responsibility from the occupier to the landowner, by making the latter directly and solely responsible, but giving the remedy against the land. The landowner is made liable to pay the rent charge in spite of any contract to the contrary between him and the occupier; the rent charge if in arrear for three months is recoverable by an order of the county court, whatever its amount may be: if the land is occupied by the owner, the order is executed by the same means as those prescribed in the Tithe Acts; but if it is not, then by a receiver being appointed for the rents and profits of the land: neither landlord nor occupier is personally liable for payment; an appeal lies to the High Court on points of law; and a remission of rent charge may be claimed when its amount exceeds two-thirds of the annual value of the land. The Act does not apply to the particular kinds of rent charges mentioned above.

The Tithe Acts do not apply to the City of London, which has always had its own peculiar customary payment regulated by episcopal constitutions of 13 Hen. III. and 13 Ric. II. and statutes of Henry VIII., confirming a decree of the Privy Council, under which the rate of tithes was fixed at 16½d. for every 10s. rent, and at 2s. 9d. for every 20s. rent of houses, shops, and the like by the year. Provision was made by statute after the Fire of London for certain annual tithes to be paid in parishes whose churches had been destroyed, and there have been local Acts from

time to time since with regard to particular parishes therein.

Title Guarantee Companies apply the principle of corporate indemnity to the protection of those interested in real estate titles, either as owners or lenders. They are of the class of indemnity companies in which technical skill and experience in investigation of risks are relied upon to protect the guarantor from loss. They are peculiar to countries where the title to real estate is a matter of public record, and where the complexity of the record and the variety of possible liens and encumbrances have made it difficult and expensive to determine whether the title is good. The only country where they have reached large proportions or achieved success as independent business enterprises is the United States. In Australia no investigation of a title to real estate is necessary, because before the land passed into individual ownership the Government adopted a system of State registration and guarantee of title, so that its certificate of registered title was universally accepted. In certain other countries there is neither registration of title nor recording of deeds; the title-deeds are preserved and passed from owner to owner, and are accepted on the authority of the records and opinions of family solicitors. In the United States, however, there have been from the beginning Acts providing that all deeds and mortgages be recorded, and the records, when properly made, constitute legal notice to all the world of their contents and claims. At the same time, there are other records of wills, suits, judgments, taxes, and mechanics' claims which may encumber the title. In the great cities these various records became in course of time so voluminous that the proper investigation of them, and the determination of the validity of the title in view of them, required the best skill of an experienced lawyer and involved very heavy expenses. On a re-sale of the property the new buyer did not rely upon the lawyer who had made the examination for the seller, but felt called upon to employ and pay his own lawyer, who had to go over the same work again, and more, for with each new transaction the history was getting longer. The delay and expense involved were great, and yet the owner had little or no protection, for a lawyer is not held to guarantee the correctness of his opinion.

The first legislative grant of corporate authority to guarantee titles to real estate was included in the charter of the New York Guaranty and Indemnity Company, a trust company incorporated in New York by Act of the Legislature in 1864; but the power to guarantee titles was never exercised. In 1869 the Real Estate Assurance Company of the City of New York was chartered with the sole object of insuring the validity of titles, but was never organized. In 1871 a pamphlet was issued by a member of the New York bar, calling attention to the business carried on by the Prussian Mortgage Insurance Company of Berlin, and outlining plans very similar to those now followed by the principal title guarantee companies of the United States; but the pamphlet seems to have been forgotten. The first company actually to undertake the guarantee of real estate titles was formed in Philadelphia, Pa., in 1876. It differed from the Prussian Mortgage Insurance Company (which guaranteed titles merely as an incident in its business as a dealer in, and custodian and guarantor of, mortgages) in that its main business was the issue of a policy of guarantee on a transfer of title to land. The advantages of its method were immediately recognized. Corporations to carry on the business were organized in Washington, Baltimore, Boston, and New York in the order named, and subsequently in nearly every considerable city in the United States.

In order to be independent of the inaccurate and clumsy methods of the public record offices, title guarantee companies generally compile in their own office a copy or digest of all the real estate records of the locality in which they are established, maintaining for this purpose a staff of skilled clerks. To make the necessary examination of a title prior to the issuing of a guarantee, they require continually a body of experienced real estate lawyers. By these means a title can be examined and guaranteed in a week, whereas thirty or forty days was formerly required. This has done much to make real estate available capital, for individual and corporate lenders on mortgage accept the guarantee of the companies as the best evidence of title, and loans can be had without the delay that once prevailed.

The expense of maintaining the staff of clerks and lawyers is great, amounting to half of the gross charges on titles guaranteed. Strictly speaking, the risks outstanding are also large, running up to $100,000,000 a year for a single company in New York City; but in well-managed companies the losses are very small, not exceeding 2 per cent. of the gross charges on titles guaranteed, so that the outstanding obligations should scarcely be called risks. In spite of the office expenses, the charges for first bringing a piece of land under the guarantee are no more than owners were in the habit of paying each time for examination and opinion by counsel, amounting to about one-half of 1 per cent. on the value of the property or on the amount of the mortgage; and when once the guarantee has been issued, it is re-issued on a subsequent sale or mortgage on short notice and for a small fee. The largest capital employed is that of the leading company of New York City, which amounts to $2,500,000. From that it runs down to $100,000 in some of the smaller cities. (C. H. K.)

Titusville, a city of Crawford county, Pennsylvania, U.S.A., on Oil Creek, and on the Dunkirk, Allegheny Valley and Pittsburg, and the Western New York and Pennsylvania railways, in the north-western part of the state, at an altitude of 1181 feet. It is in the heart of the Pennsylvania oil region, and is regularly laid out on a level terrace, divided into four wards, has a good water-supply, pumped from wells, and is well sewered. The industries are chiefly connected with the refining, pumping, and transporting of petroleum. It has oil-wells, refineries, tanks, and pipe lines. Population (1890), 8073; (1900), 8244, of whom 1573 were foreign-born and 106 negroes.

Tiverton, a municipal borough, market town, and railway station in the Tiverton parliamentary division of Devonshire, England, at the confluence of the Exe and the Lowman, 14 miles north of Exeter. A canal 11 miles long connects Tiverton with the limestone quarries of Burlescombe. The system of waterworks has been improved, a public park provided, and "homes" for twenty-four inmates erected. Area, 17,680 acres. Population (1891), 10,892; (1901), 10,382.

Tivoli, a town and episcopal see of the province of Rome, Italy, 17 miles east-north-east of Rome. Five miles west are the sulphur baths of Acque Albule, which were known to the ancients, and are now again frequented by over 40,000 persons annually. The temperature of the water is 75·2° Fahr. The falls in the river afford electric power for lighting Rome, as well as for driving several factories in Tivoli itself. Population (1881), 9730; (1900), about 11,500.

Tlaxcala, a state of Mexico, bounded on the N., E., and S. by Puebla, and on the W. by Mexico. Area, 1595 square miles—the smallest state in the republic. Population (1879), 138,988; (1900), 172,217. It forms a part of the central plateau, and is consequently in the cold region, its mean altitude being between 6000 and 10,000 feet. Three railways cross the state. It is essentially an agricultural state, cereals and pulque being the chief products. The annual value of the commerce is about $8,000,000 (silver). The capital TLAXCALA, with a population of 2847, the most important town in the state, has fine buildings, and is connected with the city of Mexico by the Santa Ana and Tlaxcala railway. The principal towns are Chiautempan (5000 inhabitants), Calpulalpan San Antonio, Tlaxco San Augustin, Huamantla, Barron-Escandon (or Apizaco).

Tlemçen, a town of Algeria and seat of a sub-prefecture in the department of Oran, near the frontier of Morocco, 80 miles south-west of Oran, 2500 feet above the sea, on the north slope of mountains 4800 feet high. Its seaport is Rashgun, and it has been placed in railway communication with Oran by way of Sidi-bel-Abbès. It is the chief town of a wide district exporting olive oil, corn and flour, wools, and onyx. Population (1900), 34,672, of whom 3812 were French.

Tobago, the most southerly of the Windward group of the British West India Islands. The products are sugar, rum, and molasses (all on the decline), and coffee, cacao, and nutmegs. But in the last year or two of the 19th century many thousands of rubber trees were planted in the island. Population (1885), 19,363 (principally negroes, there being but few whites); (1901), 18,750. Scarborough, the capital, on the south side, had in 1891 a population of 919. The mean annual temperature at sea-level is about 81°. The average annual rainfall is 66 inches on the windward side, the wettest months being June to December. Imports (1898) £11,657, exports £19,401. Revenue (1898) £8107, expenditure £8386. The religious denominations of Anglicans, Roman Catholics, Moravians, and Wesleyans maintain 25 schools, with about 2874 scholars, assisted by a Government grant of £1000. Till 1889 the island formed part of the colony of the Windward Islands, but in that year it was made part of the colony of Trinidad and Tobago, administered by a commissioner, the fiscal arrangements of the two islands being kept distinct. In 1899 it became a ward (under a warden and magistrate) of the colony, and its revenue, expenditure, and debt were merged in those of the united colony, the laws of Trinidad becoming, with some exceptions, the laws of Tobago.

Tobolsk, a Russian government in western Siberia, extending from the steppe provinces of Akmolinsk and Semipalatinsk in the S. to the Arctic Ocean in the N., and having the provinces of Orenburg, Perm, Vologda, and Archangel on the W., and Tomsk and Yeniseisk on the E. It has an area of 539,660 square miles, and its population, which was 1,283,000 in 1882, numbered 1,438,482 (domiciled only) in 1897, of whom 726,502 were women, and 86,398 urban. In 1899 it rose to 1,474,804 (87,148 urban), of whom about 118,000 were exiles and their families. Small as this increase was, it was largely due to immigration, there having been 47,000 immigrants from 1891 to 1895, and 41,800 in 1896. At the present time it is considered that no more immigrants can be taken into the southern districts of Yalutorovsk and Kurgan; immigration is consequently directed into the district of Ishim, and even into the woody and marshy tracts (*urmans*) of the districts of Tara, where some 12,600 persons settled in 1899. The population is practically all Russian, except for some 42,000 Tatars in the south, 22,500 Ostyaks, 6000 Samoyedes, and from 4500 to 6000 Voguls. There are, moreover, about 5000 Germans and Finns, some Jews in the towns, and about 1000 Tziganes. The government is divided into ten districts, the chief towns of which are: Tobolsk, Berezoff (1073), a small town standing alone in the dreary tundras, Ishim (7160), Kurgan (10,579), Surgut (1120), Tara (7230), Turinsk (2940), Tyukalinsk (1180), Tyumen (29,588), and Yalutorovsk (3450). The standard of education is still very low; in 1897 there were only 701 schools, attended by 1400 boys and girls in the middle schools (7 gymnasia), 6000 in the schools in towns, and 17,340 in the village schools.

Agriculture is the chief occupation, and Tobolsk is fast becoming a vast granary from which corn is exported to the northern provinces of European Russia. In 1896 the total cereal crop amounted to 6,548,090 quarters, but 2015 tons of hemp seed and 3100 tons of linseed were also grown. The total area under cereal crops in 1900 was 3,334,600 acres, and the average yield in 1895–99 was: rye 10,250,000 poods, wheat 22,709,000 poods, oats 22,103,000 poods, and barley 2,790,000 poods; also potatoes, 8,500,000 poods. The lack of improved agricultural implements places many obstacles in the way of the farmers, but efforts are being made by the local authorities to bring such implements into more general use. Cattle-breeding is carried on on a large scale, nearly 110,000 horned cattle and more than 150,000 sheep being killed every year within the province. There are no exact figures, owing to the difficulty of ascertaining the number of cattle brought for grazing from the steppe provinces. Dairy-farming has made remarkable progress since the trans-Siberian railway has been built, numbers of agents coming from European Russia and from western Europe to purchase butter, eggs, and fowls in the villages. More than 200 dairies, of which some 12 are on co-operative principles, have grown up, the aggregate production being estimated in 1900 at about 90,000 cwt., or 3,000,000 roubles' worth. Apiculture and fishing retain their importance. Manufacturing industries, as carried on in factories, are still insignificant; in 1897 they employed only 7400 workers, and showed a return of only 6,287,000 roubles. Domestic industries, on the contrary, are widely spread, especially carpet-weaving and the making of cheap rifles and all sorts of wooden ware. Navigation on the rivers of Tobolsk has developed considerably (see SIBERIA). The yearly returns of the many fairs which are held in the province are valued at 15,000,000 roubles' worth sold; the most important is that held at Ishim.

(P. A. K.)

Tobolsk, the capital of the above province, on the right bank of the Irtysh, nearly opposite its junction with the Tobol river, 172 miles north of the Tyumen railway station on the North Siberian Railway. It is an out-of-the-way town, visited only by steamers during the summer. It has, however, a good archæological and natural science museum, which issues a valuable annual report, gymnasia for boys and for girls, a theological seminary, and 17 other schools, and various educational and philanthropic institutions. Fishing is the chief occupation of the inhabitants and of its merchants, who keep their own steamers and send out fishing crews down the Ob. The merchants also carry on a considerable trade with the natives farther north, receiving fish and furs in exchange for grain, flour, salt, &c. Population (1899), 22,752.

Tocantins. See AMAZON.

Todmorden, a municipal borough (since 1896) and market town, Yorkshire, England, partly in the Sowerby parliamentary division of the West Riding and partly in the Middleton parliamentary division of Lancashire, 13 miles west of Halifax, on the Calder, with a station on the Lancashire and Yorkshire Railway. A new chancel was added to the church of St Mary's in 1896. Population (1891), 24,478; (1901), 25,419.

Togoland, a German colony in West Africa, on the Gulf of Guinea. It is a mountainous country, being situated chiefly on the southern escarpment of the Sudan plateau. Two ranges, of which one is a line of hills parallel to the plateau margin, traverse the country from south-west to north-east. The coast is a low, sandy foreland, formed of the detritus deposited by the sea current called Calema. Large coast lagoons receive the numerous rivers, the Mono, Haho, Sio Tapjie, and Volta. The last is the largest, and receives a number of affluents which rise on the plateau. In its middle part it forms the boundary of the country; it becomes navigable at Krachi.

Boundaries and Population.—The southern boundary is the sea. In the east the boundary between Togo and French Dahomey, by Franco-German agreement of 1897, is the middle of the river Mono as far as 7° N. and in a generally northerly direction to 11° N. The western boundary, between Togo and the British Gold Coast, was settled by Anglo-German agreement of 1890;

it leaves the coast near Lome and proceeds in a zigzag line to where the Deine river joins the Volta; it follows this river to its junction with the Daka, and continues from here in a manner agreed upon in 1899, so as to secure the neutral zone of Salago; this remains to be settled definitively. The area is estimated at 33,000 square miles, with 3,000,000 inhabitants.

Meteorology.—There are two wet seasons the first lasting from March till June, the second and shorter one from September to November. The greatest heat falls in the winter months. A dry wind, called harmattan, which carries great quantities of red sand, is specially remarkable.

Flora and Fauna.—The lagoons on the coast are surrounded by dense belts of reeds, and the coast-land is covered with low, impenetrable bush. Large groves of oil-palms are planted. On the hills the baobab and hyphæna palm are characteristic, and on the plateau are grass and the shea butter-tree. Animal life is much the same as in the other parts of tropical Africa; it is poor on the coast, and in the interior the influence of the Sudan steppe is noticeable.

Ethnology.—The inhabitants are Sudan negroes. In the north they are Hausas, in the west they speak the Tchi dialect, while on the coast the Ewé language is spoken. The Adeli and Aprosso have a dialect of their own. In the north they form small though well-organized states. The whole country is well populated; on the coast the inhabitants are agriculturists, in the interior they raise cattle, and the Hausas are successful traders, who traverse the country in large caravans.

Government and Forces.—There are three Government stations in the interior and on the coast. Lome is the residence of the Commissioner, who is also chief justice. There is a force of 250 coloured soldiers, under one white commissioned and ten non-commissioned officers.

Religion.—The inhabitants are partly Mahommedans, partly believers in fetish. There are four mission societies, one Roman Catholic; they have several schools, which, however good, are not equal to the Government school in Little Popo.

Revenue, Taxation.—There is an import tax of 4 per cent. of the value on all mercantile goods. Certain exceptions are admitted. Liquors, powder, tobacco, and firearms are subject to a special tax. Trading firms have to pay a licence of £50 a year, and of £25 for each branch establishment near the coast, or of £5 in the interior. Firms which only import pay £30 per annum. The budget revenue for 1899 was 550,000 marks, the expenditure 789,000 marks; the imperial subvention for 1900–1901 was 270,000 marks.

Shipping.—There is direct steamship communication between Togo and Hamburg; the Woermann line sends regularly three steamers a month, and the steamers of three French lines and two English call at Togo ports. In 1898–99, 95 vessels of 110,241 tons entered the ports.

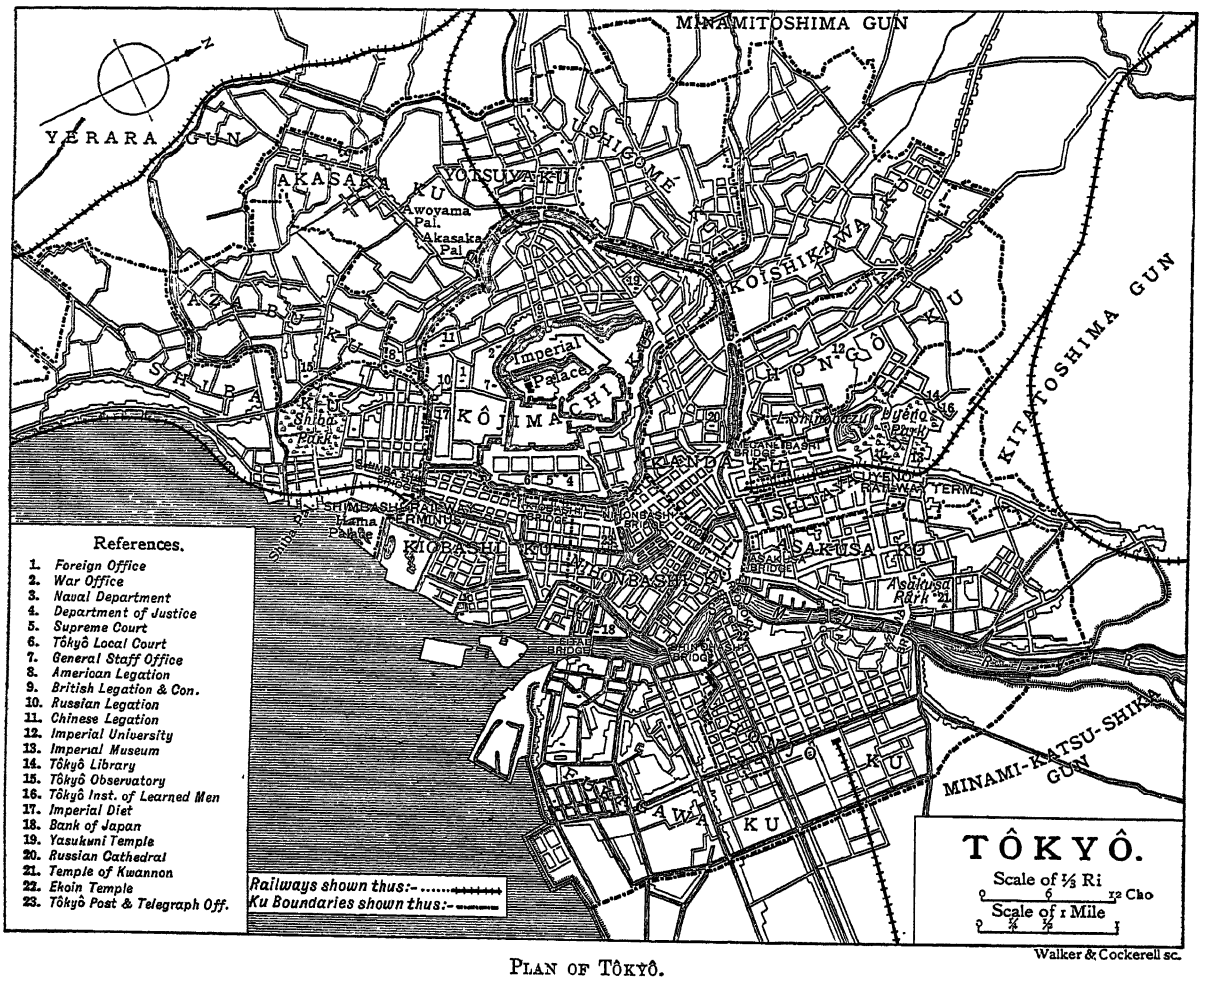
Roads, Post, and Telegraph.—Roads are gradually being pushed towards the interior. A short line of railway is in course of construction, and a jetty which ships can approach for loading purposes has been built. The colony belongs to the Universal Postal Union, and there are two post offices on the coast. Twice a week mails are sent by runners overland to the French and British post offices in the neighbouring colonies. The stations in the interior receive mails twice a month. There is a telegraph between Lome and Little Popo, and both places are joined on to Accra and Dahomey, and thus to the international cable system. There is a Government telephone line between Little Popo and Lome.

Productions and Industry.—The country is rich in natural products—palm oil and kernels, copra, rubber, ground nuts (*arachis*), shea butter of the *Bassia Parkii Sapotacea*, fibres of the *Raphia vinifera*, the *Sansevieria Guineensis*, indigo, and cola nuts, ebony and other valuable wood. Minerals have not been found yet. In the interior cattle and sheep are plentiful, on the plateau horses and donkeys. The natives are good weavers. They collect and spin the indigenous cotton, and dye it with indigo or other pigments; the country produces and manufactures very handsome shawls. Pottery and smith's-work are largely practised, and iron is being imported. Carving in wood is common, and the examples are sometimes very handsome. In 1898–99 the imports were valued at 3,029,598 marks, the exports (mainly palm kernels and palm oil) at 2,016,708 marks.

Progress since Annexation.— Since its annexation to Germany the country has been most prosperous. Trade has grown considerably. Plantations have been started, and only cocoa and tobacco have proved a failure, there being too little rain for the one and not the right quality of soil for the other. Coffee and cocoa palms thrive well, and the produce increases from year to year. Cotton has not been cultivated with equal assiduity; rubber promises good results. Peace and order have been established, and the good-will of the natives has been gained throughout the country.

See N. SEIDEL. *Die Kuste und das Vorland der Togocolonie.* Berlin, 1897.—R. BUTTNER. *Die Forschungsstation Bismarckburg und Adeli.* 1894; *Das Deutsche Schutzgebiet Togo.* Bremen, 1891. (J. VON P.)

Tokat (Armenian, *Evtoghia*), the ancient *Dazimon*, altitude 2280 feet, chief town of a sanjak of the same name in the Sivas vilayet of Asia Minor, situated on the Sivas–Samsún *chaussée*, at the mouth of a rocky glen which opens out to the broad valley of the Toranli Su, a tributary of the Yeshil Irmak. The industries are the manufacture of copper utensils and yellow leather, and stamping colours on white Manchester cotton. Near Tokat copper pyrites, with iron and manganese, kaolin, and coal are found. In November 1895 there was a massacre of Armenians. Population, 30,000 (Moslems 19,000, Armenians 10,000, Greeks 1000).



Tokay (Hungarian, *Tokaj*), a market town of Hungary, in the county of Zemplén. The phylloxera made enormous ravages in the famous vineyards, but by means of new plantations the wine industry is again reviving. Population (1891), 4815; (1901), 5110.

Tokelau. See POLYNESIA.

Tôkyô, formerly called YEDO, the capital of the empire of Japan, situated in 35° 41′ N. and 139° 45′ E., at the head of the bay of the same name on the south-east coast of the main island. The city stands on the banks of the river Sumida, which, although wide, is unnavigable by vessels of large tonnage owing to the shallowness of its mouth, due to the silt brought down by the current. A scheme was on foot in 1902 to overcome this difficulty and thereby open the port to shipping in general. Meanwhile Yokohama, with which Tôkyô is connected by 18 miles of railway, is practically the port of the capital.

Tôkyô covers an area of about 100 square miles. Geographically, it may be divided into two parts, upland and lowland (Yama-no-té and Shitamachi), which for administrative purposes are split up into fifteen districts or *Ku*, of which Kôjimachi, Hongô, Koishikawa, Ushigomé, Yotsuya, Akasaka, Azabu, and Shiba are situated in the upland portion, while Kanda, Kiobashi, Nihonbashi, Shitaya, Asakusa, Honjô, and Fukawaga are in the lowland. Suburban Tôkyô is divided into eight districts or *Gun*, which, with the city proper, collectively form the Tôkyô-Fu (prefecture), under the general control of one governor called Fu-Chiji. Questions affecting the interests of the whole Fu come before the *Fukwai*, or prefectural assembly, made up of representatives from both *Ku* and *Gun*, and a prefectural council, of which the governor is president; while matters concerning the city alone are discussed by a *Shikwai*, or municipal assembly, and administered by a municipal council, of which the Shichô or mayor is the president. The population in 1898 was 1,440,121, as compared with 1,242,224 in 1894. For many years past it has shown a steady and substantial increase. The streets

are still in many quarters narrow and irregular, and do not permit of heavy traffic. In this direction much has been achieved, however, under the Tôkyô Streets Improvement Act of 1888. The chief thoroughfares have been widened, and the excessive crowding in them no longer exists. All along the best streets, at regular intervals on each side, the willow, the flowering cherry, and other ornamental trees have been planted between the foot-path and the carriage-way. The Ô-dori (main street) is the most important thoroughfare. It runs from the Shimbashi station to Mégané-bashi or Spectacles-bridge (so called from its circular arches), and traverses the business quarters of Nihonbashi, Kiobashi, and Kanda. In the section of it called Ginza most of the best shops and bazaars are to be found. The pavement is generally composed of pebbles held together by clay, and these, in fine weather, afford a sufficiently smooth surface. With much rain, however, the clay turns to mud. The principal streets, especially those in the business part, are lighted by electricity and gas, or by good oil lamps; but, generally speaking, the illumination is poor, there being in some quarters no light whatever, and in these

PLAN OF TÔKYÔ.

it is still necessary to carry a lantern. The jinrikisha, drawn by one or sometimes two men, forms the chief means of passenger conveyance. Horse and electric trams are used in certain parts of the town, and street railways and trams are being introduced. Lowland Tôkyô, that part of the city covering the flats on both sides of the river Sumida, is intersected by a system of canals along which merchandise and tradesmen's wares are conveyed by barges. The many bridges which span these canals have always been distinctive and picturesque features of Tôkyô. The Nihonbashi (Bridge of Japan), in the district of the same name, is by far the most famous. It is the central point from which all distances in Japan are calculated. The largest bridges are those named Azuma, Umaya, Ryôgoku, Shin-ô, and Eitai, and these all serve to connect the districts of Fukagawa and Honjô on the eastern bank of the Sumida with the other portions of the city on the western. Shin-ô remains wooden, but the other four have been reconstructed of iron. Ochanomizu-bashi, a suspension bridge connecting Hongô with the Surugadai Hill of Kanda, is also a famous structure. On this hill stands the Russian cathedral, an imposing edifice dominating the view in the lowland district. The climate is mild and healthy, and for the greater part of the year very pleasant, the seasons of spring and autumn being more especially delightful. There is a regular water supply, the new water-works, commenced in 1892, having reached completion, and water is laid on to the dwelling-houses. The reservoir at Yodobashi is capable of supplying water to all parts at a pressure varying from 80 to 100 feet, and is of such dimensions as will enable it to meet the requirements of a population twice the size. The water is brought from the river Tama by the old aqueduct, 27 miles in length. Hydrants are fixed in all the streets for the use of the fire brigade, whose operations have been rendered much more effective by reason of the enormous pressure and ample supply afforded by the new

system. The fire brigade has a well-disciplined and very efficient personnel, and it does not lack opportunities for the exhibition of its skill in a town built almost entirely of wood. In 1899 there were 358 conflagrations in the Tôkyô-Fu, destroying altogether 1441 buildings. The fire brigade is not yet adequately equipped with engines of European type, but the firemen, though they rely upon antiquated methods, are nevertheless highly trained, and display at all times invincible courage. On the second day of the year a public display of the fire brigade is given at the Kaji-bashi ground, where the greatest excitement and interest are evinced by crowds of people who come from all quarters of the town to witness it. The police force is another well-trained and successful service. In 1899 its numbers were 3519 in Tôkyô-Fu, or one policeman to every 543 inhabitants. Both police and fire brigade are under the command of a single *Keishi-sokan* (inspector-general). The postal arrangements are very satisfactory, frequent deliveries being made with the utmost despatch. Telegrams can be despatched to and from any part of the city. The telephone, too, has been adopted. There are long-distance wires to Yokohama, Osaka, and other large towns, through which messages may be spoken. In 1901 there were 29 post and telegraph offices, 23 offices for post only, and 5 offices for the despatch of telegrams only. A very complete and successful system of education exists. In 1899 there were 715 public and private elementary schools, giving employment to 3053 teachers. In that year children of school age numbered 294,864, and of these 195,371 went through the course of instruction prescribed by the Ministry of Education. There are also many schools for advanced students devoted to the various branches of science, mechanics, and art, the principal of which are under direct Government supervision. Under the same control there is the Imperial University of Tôkyô, which consists of the colleges of law, medicine, literature, science, engineering, and agriculture. There are several very good daily newspapers, as well as weekly and monthly publications of all kinds. In the suburbs there are many factories, but Tôkyô as a whole cannot be described as a manufacturing city. It has often experienced earthquakes, and more than once has suffered from severe shocks. For this reason the number of tall substantial houses of brick and stone is limited, lest earthquakes may occasion loss of life and property through the fall of such heavy buildings. It has been suggested, however, that iron framework constructed according to scientific methods would reduce the enormous destruction of houses from which the people suffered in past days, and it was decided to build the palace of the Crown Prince at Aoyama of that material. The Imperial Palace, which is half European and half Japanese in its style of architecture, stands on the site of the old Yedo Castle, almost in the centre of the Kojimachi-Ku. It is surrounded by moats. The Nijû-bashi is the main entrance. To the east and south of the palace the neighbourhood has undergone great changes in recent years. It was here, at the Sakurada Gate, that Ii Kamon-no-Kami, Prime Minister of the Shogun's Government, and the first Japanese Progressive, was assassinated by the anti-foreign party in 1860. On the site of his residence a little higher up to the right of the gate now stands the War Office and the offices of the general staff. In another street, immediately facing the gate, are the Foreign Office, the Supreme Court, the Local Court, and the Departments of Justice and the Navy. The temporary buildings of the Imperial Diet, which first met in 1890, are also in this part of the capital. Adjoining the above-named buildings the new Hibiya Park has been laid out. It is modelled attractively on public gardens of the European style. The parks have always afforded to the people their chief means of recreation. The largest and most beautiful are those in Shiba and Uyeno, the latter encircling Lake Shinobazu, so famous for its lotus flowers. In Uyeno, too, are the Imperial Museum, the Imperial Library, the Zoological Gardens, and the temples of the Shoguns. The famous temple of Kwannon, the goddess of mercy, is in the Asakusa Park, in which a permanent fair is held; it is a great holiday resort of the middle and lower classes. Kudanzaka Park is approached by a long steep road. In its grounds is the Yasukuni Temple, consecrated to the spirits of departed heroes who gave their lives for the state. To the right of the temple is a museum of arms, where the old Japanese swords and scabbards, as well as trophies from China and Korea, are exhibited. The pastimes of the people for the most part take the form of out-of-door sight-seeing, regulated by the season of the year. In the spring or cherry-blossom season many picnic excursions are made into the country. One of the greatest sights is the shell-fish gathering in April, when the tide runs out, leaving the bed of the bay accessible to thousands of gay young people, who wade out in search of bivalves. Athletic sports, once altogether ignored, have become very popular. Twice in the year, in May and January, wrestling contests take place in the enclosure of the Ekoin Temple near Ryôgoku Bridge, and these evoke the greatest interest and enthusiasm. Rowing is popular with schoolboys and students. Cycling, too, is a favourite pastime, even with Japanese ladies, who are usually very conservative in their habits.

Tôkyô is the centre from which several railways radiate. The trains of the Tokai-do line, starting from the Shimbashi station, run westwards to Kôbé, thence to Shimonoseki, the western end of the main island, a distance of 700 miles. The Uyeno station is the starting-point for trains to Aomori, a town 460 miles away, at the northern extremity of the island.

(G. U.)

Toledo, a province of Spain; area, 5620 square miles; population, 359,562 in 1887, 370,012 in 1897. The birth-rate is 4·08 per cent., the death-rate 3·36 per cent., and the proportion of illegitimate children 2·05 per cent. of the births. The province is divided into twelve districts and 206 parishes. There are 250 miles of railways. The mountainous districts were until lately the abode of brigands, who found shelter in the forest-clad sierras that were so extensively denuded of timber in the last decade of the 19th century. From the woods in the lower sierras much charcoal and firewood is yet drawn, and the commons produce £70,000 yearly in this way.

The northern part of the province is richest in agricultural products, and the southern in wines. About three millions of acres are cultivated, 503,500 acres in 1897 being devoted to wheat crops, 263,822 to rye, oats, barley, maize; 70,437 to pod fruit; 109,880 to vines; and 60,472 to olives. There are extensive pasture grounds, where much live-stock is reared and excellent breeds of bulls for their popular sport. The live-stock in 1897 included 3971 horses, 24,248 mules, 22,059 asses, 14,810 cattle, 346,228 sheep, 39,349 goats, and 21,410 pigs. There is an active trade in the products of agriculture.

Toledo, capital of the above province; population, 20,837 in 1887, and 23,465 in 1897. It is on a branch of the Southern Railway. The aspect of this ancient city has not changed, and it is still the silent old-world place that attracts natives and foreigners who desire to form an idea of a town preserving so many traits of the past in its noble churches and public buildings, its narrow streets and massive houses, its Gothic, Moorish, and old Castilian ruins and monuments intermingled. The Alcazar, so often restored after fires that caused much damage, was again much injured on the 9th January

1887. The Government spent a considerable sum in once more restoring it, and it is now the military academy for infantry. A masterpiece of Covarrubia was fortunately saved from all the successive fires. Toledo has some modern buildings worthy of notice—the institute for higher education and the primary schools, the school for training teachers, courts of justice, hospitals. The arms manufactory, a mile outside the town walls, is conducted by the Government. There are many private manufactories in Toledo that rival the royal works.

Toledo, a city of Ohio, U.S.A., capital of Lucas county, on the Maumee river at its mouth, in the northern part of the state, at an altitude of 587 feet. The city is regularly laid out on a level site, covering an area of 28½ square miles, extending 8 miles along the Maumee, is divided into fifteen wards, has a good water-supply by pumping into stand-pipes, is well sewered and well paved with granite blocks, brick, wood, and asphalt. Among its fine buildings is its public library, containing 35,000 volumes. The city has a large share of the lake commerce, consisting of grain (mainly wheat), clover seed, lumber, iron ore, and coal. It is one of the most important railway centres of the country, being entered by no less than thirteen railway companies. It is also the terminus of the Miami and Erie Canal. Its manufactures are large and rapidly increasing. In 1900 there were 1050 establishments, with a total capital of $25,591,916. They employed 15,383 hands, and the product was valued at $37,372,355. The principal products, with their values, were flouring and grist mill products, $4,458,749; foundry and machine-shop products, $2,715,613; bicycles, $1,583,450; liquors, $1,458,593; tin and sheet-iron working, $1,435,089; petroleum refining, $1,392,745; and lumber, $1,376,149. The assessed valuation in 1900 of real and personal property was $53,445,760, the net debt was $6,526,204, and the rate of taxation $32·60 per $1000. The total income was $2,158,872, and the total expenditure for maintenance and operation $1,484,588. Population (1890), 81,434; (1900), 131,822, showing an increase in the decade of nearly 62 per cent. Of the population in 1900, 27,822 were foreign-born and 1710 negroes.

Tolstoy, Leo (1828– ——), Russian novelist and social reformer, was born on the 9th September (28th August) 1828, in the home of his fathers—Yasnaya Polyana, near Toula—a large country house (not the present one) built in a severely formal style, with Doric pillars and architraves, standing solitary in a typical Russian landscape. The Tolstoy family, to whom it had belonged for several generations, was originally of German extraction, and had settled in Russia in the days of Peter the Great. The first ancestor of distinction was Peter Tolstoy, at one time Russian ambassador to the Sublime Porte, and ennobled in 1724. Subsequently becoming involved in a court intrigue, he forfeited his title and estates, which were not restored to him until the year 1760, in the reign of the Empress Elizabeth. Neither his son nor his grandson were men of mark, but the latter, at the conclusion of the Napoleonic wars, was made governor of Kazan. Unfortunately, his incapacity for administration soon brought the affairs of the province into confusion, and a commission was appointed to inquire into the case, with the result that the count was dismissed from office. The disgrace told upon his health, and he died soon afterwards. His son Nicholas (the father of the great author) was born in 1797. After serving for a short time in the army he retired in 1824, and led the life of a Russian boyar. By his marriage with the Princess Maria Volkonsky, Count Nicholas in a great measure rebuilt the family fortunes, which had fallen into decay during the two previous decades. Count Leo Tolstoy was the youngest but one of the five children of this marriage, and lost his mother when he was barely three years old. Some six years later his father died also, at the early age of forty-one. Tolstoy has described his parents as Rostov and Maria Volkonskaya in *War and Peace*, but his childish recollections of them were necessarily dim and fragmentary. They are said to have been kind and good, cultured and God-fearing persons, his mother possessing the superior mind, together with a remarkable gift of story-telling. It is related of her that her girlish companions would often desert the dancers in the ballroom to sit listening to her fascinating tales. As a child, Tolstoy, though observant and thoughtful, showed no marked talent. In common with his elder brothers, he was fond of play and mischief, impatient of discipline, and disliking the routine of lessons. He was plain and very sensitive on the point, suffering keenly for want of notice and affection. This sensitiveness led him as he grew older to hide himself away from his playmates and spend hours in lonely brooding. He describes in *Childhood* how, one day, it dawned suddenly upon his mind that Death was ever lying in wait, and that to be happy one must enjoy the present, unconcerned with the future. Whereupon the youthful Epicurean flung aside his books and pencils, and, stretched on his bed, fell to munching sweetmeats and reading romances. But Tolstoy's childhood was not without its share of wholesome pleasure. Hunting and shooting, the delight of the Russian noble, occupied much of his father's leisure, and from his earliest years the boy was wont to accompany his parent. At other times he was quite happy sitting beside his father's coachman on an expedition to one of the neighbouring towns, or with his brothers running in and out of the stables and coach-houses. The tedium of the schoolroom, the reproofs of his tutor, made a reverse side to the picture, but did not prevent this fund of early memories from being, as he writes, "ever to be treasured, and fondled again and again, serving as a well-spring from which to draw my choicest treasures." After his father's death at Moscow in 1837, Tolstoy and his brothers were placed under the guardianship of his aunt, the Countess Osten-Sacken, and in the care of Madame Ergolskaya, a distant relative. The former died, however, in 1840, and the charge devolved on another aunt, Madame Jushkov, who lived in Kazan. Madame Jushkov was a typical Russian lady of her class. Keeping open house, fond of gaiety and society, her ideas on moral questions were liberal in the extreme, though not more so than those of most women of her rank and day. Religion was indeed a factor in her life, but acted rather as a stimulant to her emotions than as a guide in her daily conduct. Tolstoy was eleven years old when he became subject to her influence—an influence which he subsequently regarded as having been the reverse of beneficial. A French tutor was engaged for him and his brothers, prior to their entrance into the University of Kazan. Outside the hours of study Tolstoy spent his days either in solitary rambles, during which he reflected on the problems of life, or in violent exercise at the gymnasium (the only form of athletics enjoyed by boys of his position in Russia). Thus the physical and philosophical impulses of his nature were developed in equal measure, and these two conflicting forces began their lifelong duel. Only in later years did the philosopher outweigh the man of action in Tolstoy's vigorous personality.

Childhood.

In 1843, at the age of fifteen, he entered the University of Kazan, and gained with his college cap and uniform what he prized most, his independence. The lax rule of the university—which was of no high scholastic repute,

giving ready admittance to the sons of the rich and noble—enabled him at the same time to enter the world of society and study its complex problems at leisure.

At college. Kazan was in those days a real paradise for such as sought happiness in social excitement, dining, and dancing. No city in Russia was so given up to the pursuit of pleasure. Among these scenes of luxury and licence the students of the university played a prominent part. Granted an unusual degree of liberty, together with an indifferent system of education, even those who were desirous of serious study made little progress, while the greater number spent their time in parading the town and letting off their exuberant spirits in all sorts of horse-play. Belonging mostly to the families of rich landed proprietors who wintered in Kazan, they held themselves a privileged community, and the inspectors of the college were practically powerless over them. Amid such influences the boy soon ripened into the man. The constant succession of balls, picnics, and parties finally wearied and disgusted him. Over-strung nerves and irritability showed how the poison distilled from excess of pleasure had entered his system. The pages of *Youth* are eloquent of deadly ennui. He is for ever seeking "Her," engaged in an undefined "pursuit of the Well-beloved," with a half spiritual, half physical longing. At intervals in this quest of the unknown he devoured the novelists of his day, chiefly Dumas and Eugène Sue. He already thought deeply on the object and aim of existence; forming new ideals, aspiring to noble deeds, seeing himself in imagination by turns now a passionate lover, now a leader of men. His forceful nature led him constantly to extremes. A story which, even if not true, illustrates the common opinion of Tolstoy, is told of how in his youthful pursuit of novelty he felt a longing to fly. The attempt, however, brought him to the ground with an injured leg. He says of himself that he was always endeavouring to be original, and to tread unbeaten tracks. Partly in consequence of this feeling, he determined to enter the school of Eastern languages. His first attempt was unsuccessful, but finally passing in through the medium of a supplemental examination, he took up Arabic and Turkish. These studies, however, proved uncongenial to his versatile nature, and failing to distinguish himself in them, he turned his attention in 1845 to the school of law. Here he met with equal discouragement. The professors—all Germans, and many of them not knowing enough Russian to make themselves understood—were favourite butts for the students' wit. There was practically no serious teaching, nor any personal interest shown in the pupils. Tolstoy's evil genius had once more cast him in stony places and left him to work out his own salvation. History, religion, and law now claimed his attention in his final effort to gain the university diploma. In religion his opinions had undergone a great change. From the child's unthinking acquiescence in a hereditary faith had sprung absolute unbelief. History he held a useless form of knowledge. "Of what avail," he said, "to know what happened a thousand years ago?" Hence he neglected the lectures on these subjects, absented himself from the examinations, was confined in the university gaol for irregular attendance, and ended by coming out but moderately well in the yearly examination. The conviction that he was wasting his time forced itself upon him. An idle, dissipated life had told upon his health, and early in 1847 Tolstoy asked permission to go down, "on account of ill-health and private reasons." Thus ended his college life, which from an educational point of view he had treated as a jest. Somewhat of an enigma as he was to his companions, with his alternate fits of feverish gaiety and melancholy abstraction, aristocratic hauteur and liberal views, there was yet found a little band of students to accompany him on the first stage of his journey homewards. While probably admiring the original bent of his mind, they little dreamed their late comrade would one day be acclaimed as Russia's greatest thinker and novelist.

Tolstoy went back to his estates with fresh hope and energy, determined to ameliorate the condition of his peasantry and fulfil the duties of a landlord.

The youthful reformer. Rumours had reached him at Kazan from time to time of the recurring famines, revolts, miseries of the serfs. In 1847, as often before, the crops failed to suffice for the needs of the starving people, and whole districts set forth to petition the Tsar for food. Here was a vital problem requiring prompt solution. In the course of desultory reading at the university he had studied the writings of Jean Jacques Rousseau, and the Frenchman's plea for Nature, honest work, and simplicity of life had impressed him greatly. Fired with enthusiasm, he now entered heart and soul on the task of realizing this ideal. Unfortunately, he was as yet without sufficient moral stamina to withstand recurring disappointments and to combat the suspicions of the serfs. The youthful reformer lacked the patience necessary to deal with the deep-rooted mistrust engendered by years of oppression and neglect. After six months of struggle with this discouraging state of things he temporarily gave up the attempt, and we find him in St Petersburg taking up for a time the broken threads of his education. But with the restlessness of transition strong upon him he soon returned to country life, and in company with his brother Sergius gave himself up to hunting, gambling, carousing with Zigani dancers, and throwing all serious thoughts to the winds. *The Landlord's Morning* may be taken as a picture of this stage of Tolstoy's life. The inevitable reaction soon came. Oppressed by debts and difficulties, in the spring of 1851 he betook himself to the Caucasus, where his eldest brother Nicholas was stationed with his regiment. At Pyatigorsk, a small town at the foot of the mountains, he rented a cottage for about twelve shillings a month, and lived there with the utmost frugality.

Finally his brother's persuasions, aided by the influence of relations in high places, led him to enter the army.

Enters the army. He passed the necessary examination at Tiflis, and joined the artillery in the autumn of the year. At that time Russia was much disturbed by the lawlessness of the Caucasian races. Bands of Circassians were constantly on the move, plundering and looting. The punitive expeditions in which Tolstoy took part were his first taste of warfare. Neither his military duties nor his love of sport entirely absorbed him, however. The great power which had hitherto lain dormant now awoke. He began to write, and within the next few years produced some of his finest works. Nekrassoff, the editor of the Russian *Contemporary*, accepted *Childhood*, the young author's maiden effort. In accordance with the common practice, he received nothing for the MSS. Publication of a first attempt was considered ample payment in those days. Tolstoy was now twenty-four years of age. *Childhood* was followed by *The Landlord's Morning*, *Boyhood*, and *Youth*, in quick succession. His early aspirations were revived in these pages, which reflect the doctrines of Rousseau. "You neither know what happiness is nor what life is," he writes to expostulating friends. "Once taste life in all its natural beauty, happiness will consist in being with Nature, seeing her, communing with her." His philosophy notwithstanding, Tolstoy felt a pardonable desire for promotion, which was slow in coming to him. Some verses ascribed to him (an authorship never denied)

making fun of the general during the siege of Sebastopol, which appeared in print, may possibly have had something to answer for. Be that as it may, the spirit of unrest and dissatisfaction was moving Tolstoy to return home, when rumours of hostilities arose, and the Crimean war burst into flame. He promptly volunteered for active service, and asked to be allowed to join the army on the Danube, under the command of Prince Gortschakoff.

The Crimea.

In the early part of 1854 we find him encamped before the walls of Silistria, a town of Bulgaria, which Gortschakoff had invested. At the very height of the bombardment, however, Austrian intervention prevailed, and the siege was raised. The din of battle was hushed, and revelry took its place. At the ball which promptly celebrated the event Tolstoy felt ill at ease. The joyous music and babel of tongues jarred on his sensitive ear, fresh from the moans of the wounded and dying. He went up to the prince and asked leave to start for Sebastopol. Permission being granted, he hastened from the ballroom, and left Silistria without delay. He now exchanged the offensive for the defensive. Shot and shell fell like hailstones on the bastions of Sebastopol. Courage, fortitude, presence of mind were at every moment demanded, while assault followed assault, until at last the overwhelming strength of the Allies compelled the Russians to retreat. Throughout that trying time Tolstoy cheered his companions, whiling away many a weary hour with jest and story. Amid this "wrackful siege of battering days" he wrote those *Tales from Sebastopol* which earned him instant literary celebrity, and caused the Emperor Nicholas to issue special orders that he should be removed from a post of danger. An official despatch recounting the events of the siege was next written by Tolstoy at the command of his superior officer, and with the charge of this document he was shortly afterwards sent to St Petersburg. He was never again on the field of battle.

At St Petersburg.

Tolstoy returned home filled with new impressions. Sad at heart and sick of the horrors of war, he came back with a feeling of brotherly love for the common soldiers, whom he had seen day by day doing quiet deeds of courage and devotion, fighting for their country without hope of reward, without fear of death. He contrasted them with the more self-seeking nobles, and felt their superiority. The stirring scenes through which he had passed, the simple faith of his men, all had helped to renew his belief in God. Preceded by the fame of his descriptions of Sebastopol and the Caucasus, he arrived in St Petersburg to find himself the object of a general ovation. The *Sovremennik* (*Contemporary*), in which Tolstoy's first work, *Childhood*, had appeared, numbered among its contributors the foremost writers of the day. To be admitted to their ranks was considered by them an honour equivalent to the award of a *fauteuil* in the French Academy. They welcomed Tolstoy with open arms, the veteran novelist Tourguenieff in particular hastening to greet him on his arrival, and begging him to make his house his home. Society was equally eager to open its doors to the young soldier-author. His vivid and dramatic pictures of the war had been widely read, and had created a profound sensation. The great official world of St Petersburg proceeded to offer him a brilliant series of entertainments in which he found himself the central figure. It is not surprising that this combined adulation from literary men and society overcame for a time the growing asceticism of his character. Yet it also in a measure hastened its development. Even while borne swiftly on the current of pleasure, his strenuous nature gradually reasserted itself. In the pages of *My Confession* Tolstoy describes the phases of this mental unrest. The narrowness of a literary clique soon became irksome to his dominant character. His passionate desire for truth brought him into frequent conflict with those who paid more regard to convention. With Tourguenieff especially he found himself constantly at variance. A friendship between natures so diametrically opposite, between two men who might be described as leaders respectively of the old and the new school of thought, could not long subsist. Mutual admiration does not imply sympathy. Tourguenieff presently wrote to a friend, "I regret I cannot draw nearer to Tolstoy, our views are so opposed, the one to the other." And these differences of opinion gradually led to a complete estrangement. On the other hand, in Fet, the poet, he found a lifelong friend. Others of his intimates were Nekrassoff, the editor of the *Contemporary*, already mentioned; Katkoff, the celebrated journalist; Droushinine, Grigorovitch, Fet, and Ostrovski, the dramatist.

Russian popular movement.

While Tolstoy was thus waking to a sense of distaste for his environment, a great event was pending. With the accession of Alexander II. in 1855 a wave of progressive policy—set in motion by the Tsar himself—stirred the bureaucratic circles of Russia, and while fiercely resisted by some of the nobility, met generally with cordial encouragement. The emancipation of the serfs became the burning question. "The People!" and "Progress!" were the cries quickly caught up by the press of Russia and of Germany also. It was in Germany, indeed, that the novel of humble life sprang into being, Gotthelf leading the way with his tales, *Uli the Serf* and *Uli the Tenant*. Auerbach followed with his village stories, which opened up a new world of thought; Stifter and a host of others brought up the rear. This new impulse in literature soon spread to Russia. Tourguenieff in his *Sportsman's Tales*, Grigorovitch in *The Village* and *Anton Goremika*, showed their sympathy with the moujik. But above all others, Tolstoy was most deeply and lastingly affected. Awakened by this echo from without of his own inmost yearnings, he realized at last the true bent of his mind. "The People" became his watchword. One increasing purpose henceforth ruled his life, and gradually brought into harmony the inequalities and contradictions of his character. Roused from the inertia which had been caused by nerves and hypochondria, he wrote *Polikoushka*, a painful story dealing with the ills of serfdom. His active brain then turned to considering the meaning and scope of the catchword "Progress," and fully to do this he determined to go abroad and study the educational and municipal systems of other countries. After some delay he finally started for Germany in January 1857.

Foreign travel.

Tolstoy has only three times crossed the Russian frontier, and these journeys were all undertaken between the years 1857 and 1861. Since then he has been rooted to the soil. On this first trip, Germany and Italy were hurriedly visited. He also made a short stay in Paris, which had attractions for him in the society of several Russian friends, among whom were Nekrassoff and Tourguenieff. With the latter he had not yet come to open rupture. From Paris he went to Lucerne. An incident which occurred there, and is reproduced in his semi-autobiographical *Lucerne*, shows the workings of his spirit. He tells how a wandering musician stood one day in the hotel courtyard, and after his performance asked in vain for alms from the convivial crowd assembled. Tolstoy, in the person of the hero, then indignantly came to the rescue, brought the poor minstrel into the hotel, and, moved to wrath with the churlish waiters who were

unwilling to serve him, ordered a private room where he himself supplied his guest's wants, and sent him away happy with a double lining to his pockets. Of his successive journeys westwards, the third alone was of long duration and of corresponding importance in its results. Prior to this last visit to foreign parts, his time was spent between Yasnaya Polyana and Moscow, often in the company of his friend Fet. On a bear-hunt together, Tolstoy narrowly escaped death, an incident which he graphically describes in his *Fourth Reading-book for Children* (20th ed., 1900, &c.). Fet also mentions it in his *Reminiscences*. His departure was finally hastened by the serious illness of his brother Nicholas, who had gone to France to recruit his failing health. Tolstoy, after halting in Berlin and Dresden, joined him, but only to endure the grief of witnessing his end. Nicholas died on the 20th of September 1860, and Tolstoy's letters of that period show how deeply he was affected by the death of his brother. It gave a yet more serious turn to his thoughts. In a letter to Fet he reverts to his old trouble, the enigma of life. "In truth," he writes, "the position in which we stand is terrible." This mental gloom probably still hung over him during his wanderings through Italy. There is no record of his impressions of Rome, Naples, Florence. Turning his footsteps northwards, however, he began to take renewed interest in social conditions, elementary and monastic education, and the general subject of his quest. From Paris (where his friend spoke of him as "singular indeed, but subdued and kindly") he went to London in 1861, no noteworthy incident marking his brief visit.

Educational experiments.

The spring of 1861 found him once more at Yasnaya Polyana, where some little time before he had forestalled the Emancipation Act by freeing all the serfs on that estate. He now began digesting the mass of information he had acquired abroad, eager to put his ideas into practice. The feelings with which he reviewed his experiences were largely those of disappointment. Of the educational systems of Italy, France, and Germany, that of the last-named country alone earned his partial approval. While there he visited the universities, prisons, and working men's clubs. He made the acquaintance of Auerbach, and was greatly influenced by his ideas on village schools. He was also much impressed by the novel institution of the kindergarten, to which Frobel, the great educationist, was devoting all his energies. Determined to follow these lines, he sought and obtained permission to open a school. In his zeal he also started an educational journal called *Yasnaya Polyana*. This journal now only exists as a literary curiosity, but the essays published in it have all been reprinted in his collected works. The time for opening the school was well chosen. The liberal spirits of Russia had gained the day and won a great victory. Just two months previously the decree of emancipation (February 1861) had been sent forth. The air was rife with schemes for the betterment of the peasantry. A new era seemed to have begun. Tolstoy's school was essentially "free." "Everything that savours of compulsion is harmful," he said, "and proves either that the method is indifferent or the teaching bad." So that not only were no fees paid, but the children came and went as they pleased, learned what they pleased, and were subjected to no sort of punishment. It was the duty of the teacher to fix the pupils' attention, and his the blame if they failed to learn. "The student," said Tolstoy, "must have the right to refuse those forms of education which do not satisfy his instincts. Freedom is the only criterion. We of the older generation do not and cannot know what is necessary for the younger." On these principles the Yasnaya Polyana school was started in a house near that of Tolstoy. He himself taught drawing, singing, and Bible history. The Old Testament was his handbook; he held it as indispensable in any course of instruction, a model for all books. Doubts and fears sometimes assailed him, still for a year all went well. Other schools were opened on the same lines in the district, and success seemed assured. But the eyes of the Government inspectors had long been suspiciously fixed on them, and a correspondence on the subject presently ensued between the Ministry of Education and the Home Department. The verdict passed by the former was free from overt animus. "The activity of Count Tolstoy deserves respect, and should win co-operation from the Educational Department, although it cannot agree with all his ideas; ideas which he will in all probability abandon on due consideration" (October 1862). Yet there was a subtle threat conveyed in these last words which was probably not without effect. Signs of discouragement grew visible. We find the enthusiast complaining that his masters desert him, his pupils fall away. The plague of inquisitive visitors annoys him. This venture shared the fate of early blossoms, and fell victim to a frost—the frost of opposition, active and passive. At the end of the second year the schools were closed, the journal discontinued, and Tolstoy, disheartened and sick, "more," as he writes, "in mind than body," betook himself to the healthful quiet of the steppes, to breathe fresh air, to drink *koumiss*, and to vegetate. This was the end of his educational experiment, the aim of which was rather to develop the character than to educate in the ordinary sense of the term. When later he asked leave from the authorities to reopen the schools, it was peremptorily refused.

His socialistic theories were now fully unfolded. In his view the people were everything, the higher classes nothing. The latter had misinterpreted the meaning of "progress," imagining it to be synonymous with education; and hence compulsory teaching had been resorted to, with harmful results. Reading and writing played but a small part in forming a man's mind and fitting him for life. They merely rendered him more articulate. These questions should be left to the people themselves. Their demands were very clearly expressed. They knew what they wanted, and were thoroughly convinced that "in the great question of their spiritual development they would neither take a wrong step nor accept that which was false." Such was in substance Tolstoy's doctrine. "The people," he affirms, "are stronger, more independent, more just, more human, and above all more necessary than the upper class. It is not they who should come to our schools; we should learn of them." This desire to subvert society is akin to the philosophy of Rousseau, as expressed in *Émile* (livre iv.) :—

"C'est le peuple qui compose le genre humain; ce qui n'est pas peuple est si peu de chose, que ce n'est pas la peine de le compter. L'homme est le même dans tous les états; si cela est, les états les plus nombreux méritent le plus de respect. Devant celui qui pense, toutes les distinctions civiles disparaissent: il voit les mêmes passions, les mêmes sentiments dans le goujat et dans l'homme illustre; il n'y discerne que leur langage, qu'un coloris plus ou moins apprêté. . . . Étudiez les gens de cet ordre, vous verrez que, sous un autre langage, ils ont autant d'esprit et plus de bon sens que vous. Respectez donc votre espèce; songez qu'elle est composée essentiellement de la collection des peuples; que quand tous les rois et tous les philosophes en seraient ôtés, il n'y paraîtrait guère, et que les choses n'en iraient pas plus mal."

While Tolstoy's theories were thus in course of practical solution, his literary powers suffered eclipse. Tourguenieff, who lived near him in the country, writes in disgust that he "has grown a long beard, leaves his hair to fall in curls over his ears, holds newspapers in detestation, and

has no soul for anything but his property." Indeed, his time was fully taken up, for while still occupied in supporting the school, he had allowed himself to be nominated to the position of "Arbitrator," which he held for a year and some months (1861–62). This was an arduous post. The arbitrators were appointed under the Law of Emancipation to supervise the distribution of land, to adjust the taxes, define the conditions of purchase, and decide all matters in this connexion. These duties were after his own heart, and he went to work with a will. Every day he had difficult points to deal with, deputations of peasants coming to see him, the new law and the rights it bestowed on them having to be explained. The hardest of all Tolstoy's tasks was to remove the suspicion and mistrust felt by the serf towards the landlord. On the other hand, he had to contend with the nobility of the district, who were well aware of the side on which his sympathies placed him. For a year and a half he tried energetically to do his duty, but this experience led him eventually to regard the Emancipation Law as a not unmixed blessing. It had come too soon, and been granted unasked. The condition of the peasantry was worse than before. A noble impulse, inspired by love of the people, impelled Tolstoy to become their champion and interpreter. "Generations have sinned against them," he writes, "and no one deserves to live who is not ready to bear his part in undoing the wrong." This spirit of generous enthusiasm made itself felt throughout the country. The peasants respected him, and learned to look upon him as their friend.

Relations with the peasantry.

A tragic incident occurring about this period (1866) forcibly illustrates Tolstoy's character as a defender of the helpless. A regiment had recently been stationed near Yasnaya Polyana, in consequence of some five hundred convicts being at work upon the railway. In this regiment was a certain Captain N., a strict disciplinarian, who led a solitary life and was much disliked by his brother officers and his men. For trifling faults he would condemn his soldiers to unheard-of punishments. One of his orderlies in particular, a young man of some education—who had voluntarily taken the place of a comrade to free him from military service—was constantly getting into trouble, until, for some slight clerical error in a report, Captain N. ordered him to be degraded and flogged. This was too much for the poor volunteer. He followed the officer as he was leaving the orderly-room, and struck him a blow on the face. He was immediately placed under arrest, and the details of the occurrence quickly spread through the neighbouring villages. Two officers of the regiment brought the story to Tolstoy, and begged him to undertake the soldier's defence. He consented readily, and no opposition being made by the military authorities, at once prepared for the court-martial. A few days afterwards the court assembled. Warned by the president of the severity of military law, Tolstoy made answer that he was come to defend not a criminal but a man compelled to crime by force of circumstances outside his will. The plea he set up was that the prisoner was not in full possession of his senses; but this defence was not allowed to stand. The soldier was condemned to be shot, in spite of the utmost intercession Tolstoy could make. The emotion of the crowded assembly stirred by his appeal, the mute quiescence of the soldier (persuaded that death was better than the living agony of exile), the closing tragedy—all this, added to the many scenes of war and bloodshed which he had previously witnessed, made a lasting impression, and caused him to raise his voice yet louder in the cause of universal love and peace. During the preceding period of ethical experiment he published only two books, but these stand high among his works. They were *Three Deaths* (1859) and *The Cossacks* (1863)—the latter written ten years before, its leading idea being that culture is the enemy of happiness. At the conclusion of his arbitratorship, seeing his efforts partially nullified, and feeling himself overstrained and overworked, he determined to exile himself for a time to Samara, a south-eastern province. He halted on his way in Moscow, and here one night's high play cost him the MSS. of *The Cossacks*, which he sold to the editor of the *Russian Messenger* for £100 to pay his debts of honour. A pleasanter feature of this visit to Moscow lay in the renewal of his intimacy with the Behrs family, Sophia, the younger daughter of the house, being his special attraction. He finally reached Samara in the spring of 1862, and went through a "*koumiss* cure," revelling in what he called "the life of a beast of the field."

By the month of July he felt completely restored to health, and returned to Yasnaya Polyana where his sister Maria and his aunt, Madame Ergolskaya, were looking after the property. The house in which he now lived was comparatively new. The one in which he was born was sold to pay some earlier gambling debts, and had been removed bodily to an estate (Dolgoe estate) some 30 miles distant. He now felt a sense of something wanting in his home—a feeling of incompleteness took possession of him. He wanted to see Sophia Behrs, and accordingly left almost immediately for Moscow. Sophia's father was a fashionable Russian doctor, born and bred in Moscow, and a graduate of that university. He had three daughters, of whom Sophia was the second. The friendship between the Behrs and the Tolstoy families was of old standing, Countess Maria Tolstoy having been a school companion of Mrs Behrs. It was now the height of summer, and every one of consequence was leaving the city for their country seats. The Behrs family were going on a visit to their grandfather, whose estate lay not more than 40 miles from Yasnaya Polyana. Here they accordingly broke their journey, and during the pleasant days that followed Tolstoy's attachment deepened. Not long after their departure his impulse took shape, and mounting his horse, he set out for Twicy, where they were staying. His errand was a definite one; and he lost no time in fulfilling it. At first Dr Behrs demurred, unwilling to allow his second daughter to marry before her elder sister, but his objections were presently overruled. On the 23rd of September 1862 the marriage took place, and Tolstoy installed his bride at Yasnaya Polyana with the conviction that calm and contentment were his at last. Two weeks later he wrote to his friend Fet, saying that he was now happy and felt quite a new man. In his *Confession* some years later he writes: "The new conditions of a happy family circle led me away from my researches into the meaning of life. My whole mind became concentrated on the family—on the mother, the children, and the anxiety to provide due means of subsistence. The effort after perfection resolved itself into the effort to ensure the happiness of my offspring." Tolstoy thereupon settled down to country life, and though to the young countess this exile from her town friends and relations must have been somewhat of a trial, they remained on their estates for the following eighteen years, with very short intervals of absence. They had thirteen children, of whom the eldest was born in June 1863. In the bringing up and instruction of his family, Tolstoy conformed in essentials to the requirements of his position. No experiments were attempted. English and German

Marriage.

governesses were engaged, and their educational methods followed the usual routine. Both father and mother devoted a considerable amount of time to their children. Punishment was rare. It consisted in a strict "boycott" of the offender, which was not relaxed until a frank confession of fault was made—no light penalty to a sensitive child. The theory of free option in study was dropped by Tolstoy in the case of his children, but he was for ever joining in their games, taking them on his shooting expeditions, and sharing in their gymnastic exercises. Manual labour was always congenial to the great writer, and formed a natural concomitant to his pastoral existence. It was a common thing for him to mow the lawns, hoe and rake the garden beds, or when out walking to take the scythe from a labourer and wield it lustily. His overpowering vitality needed more than the ordinary man's quantum of exercise, and moreover, he upheld manual work as elevating in itself—an article of faith arising from his love of the people, and adhered to unanimously by his followers. He was devotedly attached to sport, and we find him constantly hunting and shooting. He was once (at the bear hunt before alluded to) in imminent danger of his life, and again on a more recent occasion, when out shooting hares, he severely dislocated his arm.

War and Peace and *Anna Karenina*, Tolstoy's two most widely known and finest novels, date their commencement from this period. These two novels were received with scant favour by both the Liberals and Conservatives in Russia. Katkoff, the editor who was publishing *Anna Karenina* in his periodical, introduced so many changes into the MSS. that the publication was not continued. It was due to N. Strachoff, the literary critic, that public opinion was brought to recognize the merits of these novels. Every day Tolstoy retired to his room for a certain number of hours, and whether in the humour or not, sat at his table and wrote. "Inspiration comes with writing," he used to say. Authorship he avowedly despised, yet confessed the temptation of public applause and heavy gains was too great to resist. The reading world has reason to be glad of this touch of inconsistency. The countess was at all times a helpmeet to her husband. At midday, when he stopped work, she took over his MSS. to copy neatly and place ready for him to read over on the following morning. In the evening he would confide the plots of his stories to her, and discuss the books he had been reading in preparation for them. Despite his genius for characterization, the task of novel-writing cost him a severe and determined effort. The technique of literary composition irked him exceedingly. "You cannot conceive," he writes in 1864 to his friend Fet, "how hard is this preliminary labour of ploughing the field in which I am compelled to sow. To consider and reconsider all that may happen to all the characters beforehand, and to think over the million of possible combinations, and to choose one out of a hundred thousand, is very difficult." In another letter he bemoans the shortness of life. "*Ars longa, vita brevis.* If one only had time to do a hundredth part of what one wishes, but alas! a bare ten-thousandth part is accomplished. Nevertheless, in the feeling that I am able to do it lies the happiness of your friend."

Literary work.

In the course of this correspondence interesting sidelights are thrown on Tolstoy as landowner and farmer. Not long after his marriage he wrote, "I have made an important discovery, of which I hasten to tell you. Agents, stewards, and overseers are only so many hindrances to farming! Dismiss them all and lie abed till 10 o'clock, and you will see things will certainly go none the worse. I have made the experiment, and am quite satisfied. Now to business. When you are in Orel buy me 20 poods of various kinds of string, &c., and send them to me if it does not cost more than two roubles thirty kopecks a pood with the carriage"; and in this vein he enters into manifold rural matters, the progress of crops, the illness of a favourite horse, or the calving of a valuable cow. Again the philosopher rises to the surface, and he questions Fet as to the workings of his mind.

"I don't mean in the Zemstvo nor in agriculture; these are occupations for active men, with which we employ ourselves in a perfunctory fashion, much like ants engaged in hollowing out a clod of earth—work of which the result is neither good nor bad. But what are you doing with your thoughts; how is the inner mechanism working? Is the secret spring trying to show itself, making its presence felt? Has it forgotten how to work? that is the all-important question."

At another time he pays a well-earned tribute to his wife's helpful sympathy. "She is by no means a trifler," he writes, "but is an earnest helpmeet to me." In literary matters he valued above everything the opinions of Fet and of Tourguenieff (notwithstanding his saying of the latter, "the older I grow the less I love him"). Fet, on the other hand, was an intimate and devoted friend, constantly interchanging visits with the Tolstoy family. To him the scenes of *War and Peace* were first unfolded as Tolstoy read them aloud in the quiet evenings, when the children were hushed in sleep.

It was at Fet's house (in 1864) that the violent quarrel took place between Tourguenieff and Tolstoy which nearly culminated in a duel. Many inaccurate accounts of it have been given, but the history of the rupture, as recorded by Fet, may be looked on as trustworthy. It seems that Tourguenieff in rather a boasting spirit was praising his daughter's English governess—how she had desired him to name the precise sum his daughter might spend in charity, and how, at her instigation, the young lady made a practice of mending the clothes of some of the poorest peasants. Tolstoy said brusquely that he thought it was artificial and theatrical, *poseuse*, for a daintily-dressed girl to sit sewing at filthy, evil-smelling garments in the name of charity. Tourguenieff thereupon rose, furious, from the table. "Stop saying such things!" he cried, "or I will force you to silence, with insults if need be." Peace was with difficulty restored by M. and Madame Fet, and this factious pair were despatched on their homeward way by separate conveyances. The letters which subsequently passed between them only served to fan the flame, so that even the amiable Fet was involved in the dispute and for a short time estranged from Tolstoy. Finally, after a lengthy and acrimonious correspondence, the threatened resort to arms was averted through the interposition of friends; but fourteen years were allowed to pass before a reconciliation took place. In 1878 Tolstoy, believing himself to be in a dying state, at length made overtures of peace to his brother author; overtures which Tourguenieff met cordially in the following terms:—

Quarrel with Tourguenieff.

"Dear Leo Nikolaevitch,—I received your letter to-day which you sent to me *poste restante*. I was delighted and much moved by it. With the greatest pleasure I am ready to renew our former friendship and to press your proffered hand. You are quite right in thinking I harbour no feelings of enmity towards you. If they ever did exist, they have long since disappeared, and no remembrance of you now remains save that of a man to whom I am sincerely devoted, and of a writer whose first step it was my great privilege to be one of the earliest to welcome; whose every new work has always aroused in me the greatest interest. I rejoice from my heart that our misunderstanding has come to an end. I hope to be in the province of Orel this summer, and then we shall meet. Till then I send you my best wishes, and once more grasp your hand in friendship."

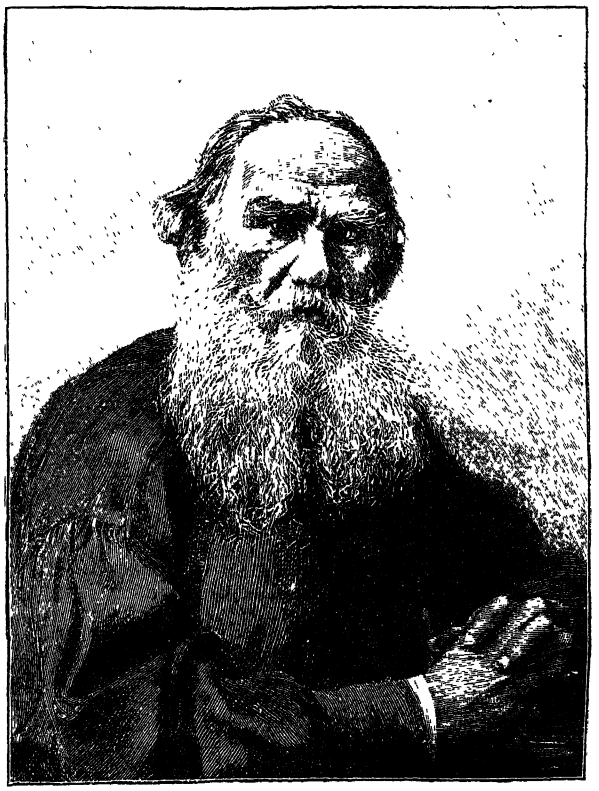
Meanwhile Tolstoy had pursued literary labours with

relentless ardour and with ever-increasing fame. Prince André (the hero of *War and Peace*) and *Anna Karenina* in turn occupied all his thoughts. Several years were given to the perfecting of these remarkable character-paintings. When the publication (1864–69) of *War and Peace* had been succeeded by that of *Anna Karenina*, he set himself to write yet another great novel, dealing with the times of Peter the Great, but after working at it for some months he suddenly abandoned the scheme. The public and private acts of the famous Tsar roused such indignation in Tolstoy's soul that he could not go on with the subject. One of the few excursions made during these years of tranquillity was undertaken in 1866 to the battle-field of Borodino, the scene of the famous fight in 1812. For two days Tolstoy wandered over the plain, investigating and taking notes, and there he drew a plan of the battle, which was afterwards published as a frontispiece to *War and Peace*. At this time, in the height of his powers and success, he confessed—with the unfaltering frankness that marks his utterances—that his creations were dearer to him than any living thing. But the continued pressure of severe nervous and mental strain was bound to affect a man of his calibre; health and spirits gradually sank, so that in 1870 Countess Tolstoy induced him once more to seek the healthful air of Samara, and subject himself to the "*koumiss* cure" in practice there.

At Samara. A strange feature of this "treatment" lay in the avoidance of meal and vegetables, the diet being strictly confined to meat. Tolstoy pitched his tent in the village of Karalieck, where the primitive life among the Bashkir nomads exactly suited his habits and disposition. He had a faculty for making himself at home with peasant folk, and was a great favourite among them. In this district there was a large community of Molochans, a sect whose tenets differ considerably from those of the Orthodox religion of Russia. They acknowledge no guide save the Bible, and reject all the rites and ceremonies of the Greek Church. Their honesty, industry, and temperance made them an example to all the country round, and caused Tolstoy to study them with special interest. So delighted was the count with this visit to Samara, that he shortly afterwards purchased an estate of over 2000 acres in the district. But his pleasure was short-lived, for not long afterwards (1872–73) the crops failed and a serious famine broke out. He thereupon opened a subscription fund for the starving population, and went from village to village taking a quantity of grain with him, and making what provision was possible in the circumstances. He also endeavoured to arouse public sympathy by drawing a dark picture of the condition of things in an article which appeared in the leading newspaper of Moscow. In all that personal devotion could effect he left no stone unturned. His own immunity from the sufferings of the poor filled him with generous remorse. "Here we are," he writes, "seated at table. Crimson radishes, yellow butter, fresh loaves make a pleasant show on the clean cloth. The garden is green and shady, and our young maidens in their muslin frocks are rejoicing in the heat of summer. But outside the evil devil Famine is busy covering the fields with blight."

Tolstoy was now making up for lost time, learning what he had failed to learn at the university. Greek was his great attraction. "Without Greek," he exclaims, "there is no culture." He also became enamoured of the writings of Schopenhauer, and for the greater part of a year (1869) devoted himself to the study of that philosopher. "Never," he says, "have I experienced such spiritual joys." Enthusiastic in everything he takes up, he assures his friends that Schopenhauer is the greatest genius he has met with. He sets himself to translate his works, and tries to enrol Fet as a co-translator. Philosophy at this stage of his life went hand in hand with sport and agricultural interests. He contemplated buying an estate in the province of Penza, but on 21st October 1869 he writes:—

Studies in philosophy.



> "The purchase of the estate in Penza has not come to anything. I have now finished the sixth volume [*War and Peace*], and I hope it will be published on the 1st of November. There are a lot of snipe. I have shot four brace, and to-day found two brace and killed one bird."

After a period of comparative rest and ease, the shadows of war and death once more encompassed Tolstoy. Two of his children died in 1873, and their loss was followed by that of his much-loved aunt, Madame Ergolskaya. "In the death of a near and dear being," he writes, "there is always something novel and unique, something sudden and unlooked-for, however long expected"; and although he is able thus calmly to philosophize, and to say further that death comes easiest to the youngest-born, and they can best be spared, still these bereavements left an enduring sadness. A mental restlessness and uneasiness came over Tolstoy, and also a desire for the exercise of a wider philanthropy. The Russo-Turkish war put the crowning touch to these feelings. God and death, war and the intricacies of life were now the constant subjects of his letters. "You will not believe what joy your last letter has given me," he writes in 1877 to his dear friend Fet. "When you speak of the existence of the Deity, I agree with everything you say, and I would wish to write much, but time fails me and it is difficult in a letter. For the first time you write to me on the Divinity of God. I have been thinking about it for a long time. Don't say that we must not think about it. Not only we must, but we ought. In all ages the best people, the true people, have thought about it." Tolstoy now resumed the study of the Bible, and took special delight in the books of Ecclesiastes and Proverbs. He treats them as a new discovery, and recommends them to his friends as having much in common with the teaching of Schopenhauer! This revived interest in religious questions was accompanied and perhaps deepened by a state of extreme depression. He was not actually ill, but imagined himself to be a dying man. It was then he reconciled himself with Tourguenieff, and in December 1878 we find the latter staying with him on a visit of three days' duration. Tourguenieff writes that he finds him "very silent, but much developed." The count on his side feels the same want of mutual sympathy as of old, and confesses that no real friendship seems possible between them.

Tolstoy now entered on the third phase of his life. He himself thus describes the stages of his mental growth. In the first phase he lived only for his own lusts and pleasures. This came to an end at the age of thirty-four. Then came the interest in the welfare of humanity, which married life cooled and obscured for a while. The striving for the welfare of mankind was mingled with the striving for personal well-being. But the third and highest phase was reached when the service of God became the motive power of his existence. All other aims grew subservient to this, and interest in the merely personal life had begun to disappear. He had passed through every imaginable grade of religious thought. As a child he had gone to church and confession unquestioningly. As a student and young man he had scorned and ridiculed religion. Later in life he became a pious and devoutly Orthodox Greek Churchman, until one day during the Russo-Turkish war he was filled with a spirit of revolt at hearing the priests pray for the destruction of the enemy,

Religious development.

beseeching the Almighty to help them to kill their hundreds and thousands. His whole being recoiled from the un-Christianity of these prayers, and he then and there renounced the Orthodox faith. For three years he had exceeded the priests themselves in the regularity of his attendance. Now he felt there was something vitally amiss, and he flung it all to the winds. Though the final step was sudden, the change in his mind had been gradual, and may be traced throughout his works. The novelist was rapidly being hidden in the philosopher's cloak, to the dismay of literary Europe. So early as 1859 Tourguenieff had exclaimed, "If only Tolstoy would not philosophize, all might yet be well." As we see during the next fifteen years Tolstoy's increasing love of mysticism (taking mysticism to mean the emotional contemplation of the relations of man to the universe), we are constantly reminded of this characteristic. His brilliant contemporaries, Gogol, Dostoievski, and others, had all in different ways been seized in turn by what may be called the fever of religion. Tolstoy was to suffer from it too. Like the flickering of a dying lamp, his imagination again shone out in *The Death of Ivan Ilyitch* and *The Power of Darkness*. Since then, with rare exceptions, his writings have been marred by his ethical reasonings. He was now fifty. While leading a life outwardly calm and peaceful, he had passed through innumerable mental struggles and vicissitudes. Of these he speaks with simple candour in *My Confession*, an autobiographical sketch which appeared in print at intervals between the years 1879 and 1882. Many theories had appealed to him in turn. At one time it was his leading idea that "the object of life should be the happiness of one's family and oneself." This had failed to satisfy him. "I lived by this rule up to a few years ago," he writes. "Then a strange state of despair, a longing came over me. I had moments of doubt and despondency. Life as it were had come to a standstill; I neither knew how to live nor what to do. I wandered about aimlessly, a prey to low spirits. For a time this mood passed away, and I took up the daily duties of life. Then again these misgivings became more frequent and more acute. The same questions were always thrusting themselves on my mind—why and wherefore? and whither?" In the orthodoxy of the Greek Church, with fastings, prayers, and rigid observances of her rites, he vainly sought an answer to his doubts; finally he broke away from a ceremonial which had become empty and lifeless to him, and built up a religion of his own. His mind, so unhinged as to have been almost on the verge of suicide, was calmed by contemplating the dumb patience of the people, "who meekly accept illness and sorrow in the steadfast conviction that all is for the best." Weary of the routine of material prosperity, of the writing of books, of the cultivation of his estates, still more drawn to the study of abstract questions, he exclaims, "How often have I not envied the unlettered peasant his lack of learning!" Impressed with the conviction that the peasant's mental ease was the result of his life of physical toil, Tolstoy tried to adopt the same habits, and for some ten years (dating from about 1880) he renounced the life of his own class as completely as it was possible for him to do. He rose early and went to work in the fields, ploughing, cutting the corn, working for the widow and orphan, and helping them to gather in the crops. He was often to be seen aiding a labourer, carrying his bundle, wheeling his barrow. He also learnt boot and shoe making, and enjoyed being praised for his skill. Thus he laboured late and early, and in these simple physical acts found the best cure for his attacks of despondency. "Simplicity! Simplicity! Simplicity!" Tolstoy seems to repeat the thought of Thoreau in the joy of his new-found peace—

COUNT TOLSTOY.

> "I say, let your affairs be as two or three, and not a hundred or a thousand. Instead of a million count half-a-dozen, and keep your accounts on your thumb nail. In the midst of this chopping sea of civilized life, such are the clouds and storms and quicksands and thousand and one items to be allowed for, that a man has to live, if he would not founder and go to the bottom and not make his port at all, by dead reckoning, and he must be a great calculator, indeed, who succeeds. Simplify, simplify. Instead of three meals a day, if it be necessary eat but one; instead of a hundred dishes, five; and reduce other things in proportion."

On this principle his food and drink, his pleasures and personal indulgences, were curtailed. Meat was given up and replaced by a vegetarian diet. Field sports—equivalents for cruelty and lust of blood—were abandoned, and his gun hidden away to rot and rust. Even tobacco was renounced as luxurious and unhealthy.

But with all his straining towards simplicity, it was in the nature of things impossible for Tolstoy absolutely to lead the life of a peasant. Labour though he might throughout the day, there was his well-appointed house to return to. He could not cut himself off from his wife and children. Friends and acquaintances could not be wholly ignored by the would-be Diogenes. Circumstances in this respect were too strong for his views and wishes. The renunciation was still only a partial one. But as the strain of a great surrender is greatest while it is still incomplete, so Tolstoy felt more and more impelled to emancipate himself from worldly concerns. The break in the long spell of country life which presently occurred only served to deepen this desire. In 1881 his eldest son went to the university, and the two next in seniority soon followed him. It became necessary for the family to be in Moscow a great deal, for the sake of the children's education. The eldest daughter had come out into society, and friends were continually calling, obliging

Tolstoy to sit and talk with them. All the elements of town life were distasteful to him. The artificiality of it; the competition of the merchants and the employers of labour; the curse of inequality—one and all weighed heavily on him. Money was an evil thing in his sight, and he gave up carrying it about with him, or even making use of it. "What makes a man good is having but few wants," he said, and he accordingly set himself to limit his wishes rigidly, and to detach his heart from all treasured objects. The year 1880 was the census year in Russia. The Government, as usual, called for volunteers to help to carry it out. Tolstoy became one of the enumerators, whose duties afforded an excellent opportunity for seeing the conditions under which the poor lived. The misery of it made him often wish to surrender all his property and have nothing more to do with lands and money, but the Government and family circumstances prevented him. In the pamphlet, *What are we to do?* he graphically narrates his census experiences. Again and again he attempted to carry his theories into effect. At last, calling his wife into his room, he explained to her that property and many possessions had become irksome to him. Wealth he now regarded as a sin. He wished to be rid of all personal ownership. In 1888 Tolstoy renounced all claim to his estates; everything was made over to his wife and children, the countess acting as trustee. True, this renunciation made little difference in his manner of life. He lived under the same roof as before, ate at the same table, wrote and read in the same study. The change was mental rather than material. He cared no longer for the growth or improvement of his estates, but gave himself up to ethical questions, and endeavoured day by day to bind himself more closely to the people. He now began to write specially for their benefit a number of simple tales which have been widely read, tales directed mostly against crying evils—the peasants' love of *vodka*, and like themes. He found willing fellow-workers in the firm of Russian publishers known under the name of Posrednik (V. Tchertkoff, and a group of friends). *John the Fool*, which was published in 1886 in the Posrednik series, is generally considered the best of these stories. *The Power of Darkness* (1885) also appeared in this series, and was written with the same object in view. Unfortunately, the popularity of these stories aroused the attention of the Government, and led to many of them being forbidden on account of their Socialistic tendencies.

Renunciation of property.

The terrible famine of 1891–92 added fresh lustre to Tolstoy's name. He and his family worked unceasingly in soup-kitchens and barns, distributing food and clothes. No true leader lacks a following. Every oppressed sect or individual turned instinctively to Tolstoy for sympathy and support, the most important case in point being that of the sect of the Doukhobors. Early in 1891 rumours began to reach headquarters of social and religious excitement fermenting among the inhabitants of the Caucasus, and especially among the Doukhobors (*q.v.*). This people, numbering from fifteen to sixteen thousand, shared their goods and property in common, and made laws of conduct for themselves, based on a simple form of religion unobscured by ceremonies or ritual. In these matters, and especially in refusing to serve as soldiers, they defied the governors of the Caucasian provinces, so that as their numbers and strength of opposition to authority grew formidable, severe measures were put in practice for their suppression. Several of their leaders were exiled, and in 1895 some hundred of them were condemned to be enrolled for three years in the so-called "disciplinary regiment." It was in that year that Tolstoy came in contact with them personally, and became deeply interested in them. He promptly identified himself with the agitation in their favour, and by his endeavours aroused sympathy for them in other countries, especially in England, where the Quakers, with whom they have much in common, espoused their cause. After many rebuffs from the Government, and many unavailing efforts to reach the kindly ear of the Tsar, the persecution of the Doukhobors at length ceased, and they were allowed to emigrate. With the aid of the Quakers and other sympathizers, sufficient funds were collected and a remarkable exodus began. No less than 7500 persons left Russia for Canada. It was in aid of these people that Tolstoy wrote and published *Resurrection*. The attack on the Orthodox Church in this novel was probably the chief cause which led to his formal excommunication by decree dated 22nd February 1901.

The Doukhobors.

His religious views are best given in his own words: "I believe in God, whom I understand to be a Spirit, to be Love itself and the Beginning of all things. I believe that the interpretation of the will of God is most clearly and most comprehensively given in the teachings of the man Christ. But I consider it the greatest blasphemy to think of Christ as God and to worship Him as such. I consider that the true happiness of man consists in fulfilling the will of God, which is that we should love each other, and act towards others as we would they should act towards us. I believe there is but one means by which to nourish the growth of love—Prayer, not public prayer in churches, which is expressly forbidden by Christ (Matt. vi. 5–13), but private prayer, an example of which is given by Christ Himself."

Tolstoy's religion.

Before attempting to define the powers and position of an author, it is best to pass in review the works which have led to his present reputation. Tolstoy the writer is a guide of unusual faithfulness to Tolstoy the man. The gradual evolution of the reformer and preacher out of the brilliant novelist is described in no pages so clearly as in his own. *Childhood* (1852), *Boyhood* (1854), and *Youth* (1855–57)—Tolstoy's first literary efforts—may be regarded as semi-autobiographical studies; if not in detail, at least in the wider sense that all his books contain pictures, more or less accurate, of himself and his own experiences. No plot runs through them; they simply analyse and describe with extraordinary minuteness the feelings of a nervous and morbid boy, a male Marie Bashkirtseff. They are tales rather of the development of the thoughts than of the life of a child, with a pale background of men and events. The distinct charm lies in the sincerity with which this development is represented. We are introduced by the child, Nicholas Irtenyev, to a number of characters one after the other—father, mother, grandmother, tutor, servants, and serfs; and are led by him from the father's study to the morning-room, and so on to the kitchen and the housekeeper's closet; and we catch, as in a magic crystal, the lifelike scenes on his waking—in the schoolroom—at his mother's side. But the apparently unconscious change of the child's mind into that of the youth—his budding thoughts, hopes, fears—form the true drama of the story. To these essays in spiritual autobiography *My Confession* (1879–82) forms a continuation. It has passages of great power and vividness, but at times the morbid brooding over the meaning of life, so frequent in these works, becomes tedious and tiresome. Of the state of mind which Tolstoy calls "nihilism" for want of a better term he gives a faithful picture. This "nihilism" is a desperate, and yet at times merely dreamy, groping for something to satisfy the soul; a fatalistic inertia alternating with spasms of feverish activity.

Tolstoy as a writer.

The following quotation from the *Confession* shows the tangle into which these gropings occasionally led: "All that men sincerely believe in must be true: it may be differently expressed, but it cannot be a lie; and consequently, if it seems to me a lie, that must be because I do not understand it." We can but recall what Goethe said of the fate of the Romantics: "Am wiederkauen sittlicher und religiöser Absurditaten zu ersticken." But in the interim between *Youth* and *My Confession*, a succession of brilliant performances had placed Tolstoy in the front rank of the novelists of the century. *The Cossacks* (1863), written round the theory that culture is an enemy to happiness, was followed by *War and Peace* (1864–69), which has been justly called a Russian epic. Within its pages Tolstoy has marshalled a panoramic array of kings, princes, and nobles, as they lived and moved during the times of the great Napoleonic wars. There are so many figures in

the picture, so much kaleidoscopic colour and movement, that the spectator often finds it difficult to follow the thread of the narrative. The leading characters all belong to the highest Russian society, whose circle—with its inflexible code of laws and customs, and a vitiated moral atmosphere affecting each member of it in a greater or less degree—links them together. The interest centres not so much in any single person as in the groups formed by four leading families of the "grand monde"—the Rostovs, Bezouchovs, Volkonskys, and the Kouragines—all bound together by common aims and interests. The men are eager to make a name and enjoy life; the women seek pleasure in gossip and romance. Peter Bezouchov and Prince André, with natures essentially different, but united by a love of truth, are the exceptions to this rule. Peter Bezouchov is one of Tolstoy's finest characterizations, drawn with a masterly hand. He is the embodiment of all that is good and bad in the Russian temperament. On the one side there is the striving after an ideal and a capacity for self-sacrifice, on the other an absence of firmness and balance. Like Tolstoy himself, he is always in doubt as to what is right and what is wrong, as to the meaning of life and death, and, like him, can find no answer to these riddles. While Peter Bezouchov is a typical Russian, a very Tolstoy, Prince André, if a less striking, is a more lovable personality. Upright and noble-minded, he yet is unable to cast off the chains of custom which have held him from childhood. He too is constantly seeking mental rest and finding none. The love-story of André and Natasha Rostov, which runs through the novel, is a poem in itself. Natasha is almost the only heroine Tolstoy has given us who wins our affections; but even she, after many transitions, sinks to the level of the *Hausfrau*, with no aim beyond the propagation and nurture of the race. There is something strained and abnormal in all the characters in *War and Peace;* but it must be borne in mind that Tolstoy winged his shafts not at men generally, but at that particular section of society to which he himself by birth and association belonged.

"War and Peace."

A long period of silence followed the publication of this novel, during which the world heard little of him. At length in 1873 he issued the first parts of *Anna Karenina*. It is without doubt his greatest production. The area of time and space in it, as in the preceding book, is large, but it has more continuity of action, and the principal characters are kept well in the foreground. It is a study of modern Russian life, in which the normal passivity of unsympathetic conjugal relations is sharply contrasted with the transient omnipotence of passion and deep love. The hero and heroine are Count Wronsky, a young soldier in a crack regiment, and Anna Karenina, the wife of an important official in the political world of St Petersburg. The parts of secondary heroine and hero are filled by Kitty Cherbatzky and her lover and ultimate husband, Levine. The central figure is of course Anna herself, an elegant and fascinating "mondaine." She is honest, frank, and well endowed by nature, and has an innate striving after truth and beauty in art and in life, but her early marriage with Karenina (who is double her age, reserved, and taciturn), while socially advantageous, has dulled and stunted her ideals. Ignorant of the meaning of love, she despises it, and it is not till she meets Wronsky that she realizes to the full the emptiness of her existence. Wronsky, young, handsome, impassioned, recognizing no principle but his own desires, offers her the rich wine of life at a draught. She tastes it, after scant hesitation; and then, flinging away her worldly position, deserting husband and child, she drains it to the dregs, only to find that poison lies in the cup. Anna and Wronsky have no true ideal to cling to. He, as their passion cools, finds the tie irksome and a hindrance to his career. She grieves for her lost and dearly-loved son, and frets as she sees that Wronsky's devotion is waning, recognizing too late that he loved her chiefly for vanity's sake, that they are slipping daily asunder, and growing displeasing to each other. Her past life is closed to her, the future opens like an abyss. The crisis has come, and swiftly obeying the impulse of her despair she seizes on death as her only weapon for wounding Wronsky and cutting the hopeless knot of her life. This pitiful end is led up to step by step with microscopic truth and insight into the springs of human action. In the married life of Kitty and Levine, on the other hand, Tolstoy describes a state of happiness of a material nature—disagreements easily bridged over, and mutual interest in their children and the pleasures of the country. Levine is the Tolstoy of fiction. The improvement and development of his estates, the life of a country squire, fail to satisfy him. The death of his brother, the birth of his child, awaken his mind to the problems of existence, and he is plunged in melancholy. Finally, relief comes to him with the words of a peasant who bids him "live for his soul and for his God." Thereupon Levine exclaims, "I have discovered nothing. I have simply opened my eyes to what I knew already; I have come to the recognition of that power which formerly gave me life and which renews life in me to-day. I am freed from error; I recognize my master." And the novel ends with the effacing of the intellect in a cloud of happy mysticism.

"Anna Karenina."

The *Kreutzer Sonata*, published in 1890, created a profound impression. Many who were previously unacquainted with Tolstoy's work read this story of love, jealousy, and revenge, and were dumbfounded by its boldness. It is a startling advance upon *Family Happiness*, published thirty years earlier. Society generally, and Russian society in particular, is ruthlessly condemned for its views on marriage and its attitude towards the vexed question of the relations between man and woman. It is also a stern indictment of music as a debasing art. Marriage, Tolstoy says, can only be condoned if spiritual sympathy exists, and then only as the means to the continuance of the race; otherwise it is a breach of true morality. The "motive" of the *Sonata* is that the ideal we should strive after is a life where the spiritual penetrates and pervades everything, and where all that is carnal is eliminated. Driven to its logical conclusion, the *Sonata* is the condemnation of marriage. But in the "Sequel" to the *Sonata* Tolstoy adds that great ideals are always unattainable, and affirms that no man can know, whilst yet striving, how nearly he approaches them. He is only conscious of his deviations.

"Kreutzer Sonata."

The views of culture forming the basis of *The Cossacks* are yet further elaborated in *What is Art?* (1898), a sweeping criticism of the philosophy of æsthetics, to which he had devoted fifteen years of thought. The reformer's conclusions condemn the art to which those very conclusions owe their authority. He dismisses as inadequate the theories which define art as the pursuit of beauty, whether beauty be regarded with Shelley and Hegel as an approximation to archetypal perfection, and thus allied to God and goodness, or with Kant as that which gives disinterested pleasure. Tolstoy sets forth his own view that art is a human activity which aims at the transmission of emotion. He proceeds to narrow the definition by demanding that the emotion shall be actually felt, and shall belong to the highest feelings to which men can rise. True art must appeal to the religious perception of the brotherhood of man, and it must find universal response. He asserts that all exclusive art is bad art, and that such subjects as sexual love, patriotism, and religious devotion should be avoided. The theory postulates a universal art which shall ignore universal human nature. Tolstoy's doctrine is indeed a surprising medley of contradictions and arbitrary assumptions. As sincere iconoclasm the book is interesting, but can hardly be constructively helpful to the lover of art.

"What is Art?"

Toluca. See MEXICO (STATE).

Tomaszów Mazowiecki, or TOMASZÓW FABRYCZNY, an industrial town of Russian Poland, in the government and 41 miles N.E. of the town of Piotrków. It has large woollen mills, steam flour-mills and mechanical works, and is rapidly developing. Population (1897), 21,041.

Tompkinsville, formerly a village of Richmond county, New York, U.S.A., and since 1st January 1898 a part of Richmond borough, one of the five boroughs constituting New York City. It is on the eastern shore of Staten Island, just above the Narrows of New York harbour. The population is not separately returned by the census.

Tomsk, a Russian government in western Siberia, extending from the Chinese frontier to about 60° N., with Semipalatinsk on the S.W., Tobolsk on the N.W., and Yeniseisk on the N.E. It has an area of 331,159 square miles, including the Altai region; and its population, which was 1,134,750 in 1882, has rapidly increased, chiefly through immigration, until in 1897 it numbered 1,929,092 (domiciled only), of whom 958,312 were women, and 128,503 lived in towns. The bulk of the population (90 per cent.) is Russian, the remainder being Ostyaks, Mordves and Zyrianes, Tatars (mostly found in the Altai), Teleuts and Telenguts (belonging to the Mongolian stem, also chiefly found in the Altai), and nomad Samoyedes (representing a mixture between the Samoyedes and the Ostyaks, and found along the Ob river and its tributaries). The immigration during the years 1888 to 1896 varied from 13,000 to 34,000 per annum. Now that the Siberian railway has been built, it is on the increase.

Since the opening of a university at Tomsk education has made notable progress, and there were in 1897 1485 primary schools with 33,000 pupils, and 18 secondary or middle schools. Agriculture is the chief occupation of the people, and excellent crops are obtained in the southern portions of the province, especially in the Altai. No less than 4,033,500 acres were under cereal crops in 1900, and the average yield in 1895–99 was 4,702,000 cwt. of rye. 10,684,000 cwt. of wheat, 7,155,000 cwt. of oats, 1.040,000 cwt. of barley—all cereal crops, 24,302,000 cwt.; also 3,363,000 cwt. of potatoes. Kitchen gardening is well developed in the south, and some tobacco is also grown, but of inferior quality. There is an experimental farm, and the different agricultural societies are making considerable efforts to bring improved agricultural implements into more general use. Cattle-breeding is very important, and butter-making in model dairies, partly co-operative, has taken a great extension; butter is already exported from Tomsk to western Europe. There were in the province in 1896 1,747,000 horses, 1,628,000 horned cattle, 2.227,500 sheep, 100,600 goats, and 452,000 pigs. Apiculture is very general, and it is estimated that there are more than 660,000 beehives in the province; the export of honey and wax is considerable. An attempt to acclimatize the mulberry tree has been made at Tomsk University, and it has been found that though no fruit is obtained, the bushes are capable of being used for breeding silkworms. Hunting is common, especially in the Narym region, and the gathering of cedar-nuts is a trade of some importance (about £5000 worth a year). Fishing gives occupation to nearly 5000 persons, and mining to some 9000. The latter is especially developed in the Altai and in the Kuznetsk district, where gold and coal are obtained. Gold was extracted in 1897 to the amount of 2274 kilogrammes, silver 4563 kilogrammes, copper 213 tons, pig iron 1540 tons, iron 1097 tons, coal 22,440 tons, and salt 15,200 tons. Industries are beginning to develop, and there were in 1898 1390 factories, chiefly small, showing aggregate yearly returns of 8,442,000 roubles. The most important establishments are distilleries, breweries, tanneries, match factories, and iron-works. The Siberian railway has its own large carriage works on the Ob. A considerable trade is carried on, especially in grain and animal products, and the sixty-eight annual fairs show returns above 7,000,000 roubles. The inner navigation on the Ob is very active (about 250,000 tons are carried every year), and is maintained by 120 steamers (7750 horse-power) and 380 barges, representing an aggregate tonnage of 274,000 tons. The exterior trade with China is on the increase and Biysk has become an important centre. The government is divided into six districts, the chief towns of which are Tomsk, Barnaul (29,408), Biysk (17,206), Kainsk (5858), Kuznetsk (20,555), and Mariinsk (8300). The villages of Novo-Nikolaevsk (16,000) and Krivoschokovo, both near the spot where the railway crosses the Ob, have grown up with an American rapidity; so also have Tatarskaya, Karachi, Kainsk, Taiga, and Sudjenka, towns on the railway. (P. A. K.)

Tomsk, the capital of the above province, on the Tom river, 27 miles from its junction with the Ob. It is connected by a branch railway 54 miles long with Taiga, on the trans-Siberian railway, and is 1780 miles by rail from Samara. Its population, which was 31,380 in 1884, numbered 52,430 in 1897. It has now a university, a cathedral, a rich library, a number of lyceums for boys and girls, a theological seminary, various schools for the clergy, four professional schools, three public libraries, one of which is free, a society for popular education (established since the foundation of the university and displaying great activity), a number of philanthropic institutions, scientific societies (naturalist, geographical, medical, musical, &c.), and two newspapers. It was believed that when the trans-Siberian railway was built Tomsk would lose its importance as the great entrepôt for the storing of goods for distribution throughout Siberia. The contrary, however, has been the case. A great number of important firms have opened storehouses, and the quantity of goods shipped on the Siberian rivers is steadily increasing. The distilleries, tanneries, candle works, match factories, &c., are insignificant, and show a yearly return of only about one million roubles; nevertheless Tomsk remains a centre for the economical, industrial, and intellectual life of western Siberia. Its activity in this respect will be increased with the extension of the university and the opening of the technical institute, veterinary institute, mining school, and theological academy.

Tonawanda, a village of Erie county, New York, U.S.A., on the east bank of the Niagara river, at the western termination of the Erie Canal, in the western part of the state, at an altitude of 576 feet. Its site is level and its plan irregular. It has considerable manufactures, now in course of development owing to the introduction of power from Niagara Falls. Four railways enter the city—the Erie, the Lehigh Valley, the New York Central and Hudson River, and the Wabash. Population (1880), 3864; (1890), 7145; (1900), 7421, of whom 1834 were foreign-born.

Tonga, or FRIENDLY ISLANDS (so named by Captain Cook, but now universally known by their native name, Tonga), lying in the South Pacific, about 350 miles S.S.W. of Samoa and 250 miles E.S.E. of Fiji. The climate is healthy for Europeans, being dry and cool as compared with that of Samoa and Fiji. A cyclone which devastated Vavau in April 1900 was the most destructive ever recorded in the group, but hurricanes are rare. In 1886 there was a serious volcanic eruption in the outlying island of Niua fo'ou, and at the same time Falcon Reef, normally awash at high water, discharged sufficient scoriæ and pumice to form a new island 50 feet high. In 1898 the island had been washed away, but in 1900 H.M.S. *Porpoise* found that a solid core of black rock had been extruded 6 feet above high water. All the volcanoes in the group were then quiescent. The average rainfall for the year is about 80 inches, the greatest rainfall in one day being 4·56 in 1890. Earthquakes are not infrequent. The people, a branch of the Polynesian stock, are the most progressive and most intellectual in the Pacific Islands, except the Hawaiians. Their path towards political liberty has been thorny. In 1875 King George Tubou, acting on the advice of the Wesleyan missionaries, absolved the natives from the service tenures which were the equivalent for rent for their lands, and granted a "constitution," with a triennial parliament in which an equal number of hereditary chiefs and elected representatives have seats. A cabinet, a privy council, and an elaborate judicial system were established, and the cumbrous machinery was placed in the hands of a "prime minister," a retired Wesleyan missionary, who induced the king to break off his connexion with the Wesleyan body in Sydney, and to set up a state church. Persecution of members of the old church followed, and in 1889 the missionary-premier had to be removed from the group by the High Commissioner. He afterwards returned to initiate a new sect called the "Free Church of England," which for a time created further divisions among the people. There are now five churches in Tonga, the Free Wesleyans (14,000), Wesleyans (2000), Roman Catholics (2731), Seventh Day Adventists (50). A few natives belong nominally to the Anglican Church. King George Tubou died in 1893, at the age of 96, and was succeeded by his great-grandson under the same title. Since the change of rulers the central Government has become perceptibly weaker, but the fear of annexation by one of the Great Powers has hitherto prevented open resistance. The king has a bodyguard of thirty men. The abandonment of the old patriarchal form of government has not proved beneficial to the people, who, having lost respect for their chiefs, now respect no one. Unable to obtain the services of the community for building their houses, they live for the most part in wretched hovels. The population decreased slightly during the decade 1890–1900, though the returns furnished by the native Government show it now to be increasing. Natives in 1890 numbered 19,085; in 1899, 19,081, in addition to 80 Europeans and 260 "others." While under the control

of Europeans the Tongans have shown some aptitude for administration; they fail when left to themselves. They pick up superficial and showy acquirements with astonishing ease, but they seem to be incapable of mastering any subject. They write shorthand, but speak no English; they have a smattering of higher mathematics, yet are ignorant of book-keeping. Their government, effective enough when dealing with natives, breaks down in all departments concerned with Europeans, and becomes the prey of designing traders. Their ambition is to rank as a civilized state, and the flattery lavished on them by their teachers has spoiled them. That they are a law-abiding and easily-governed people is shown by the fact that they pay a poll-tax of nine dollars, besides customs duties of 10 per cent. *ad valorem*.

Copra, bananas, and oranges are the principal exports; the export of copra might be quadrupled were the islands systematically planted with cocoanut trees, but since every tax-payer holds his land at the will of the Government, there is no fixity of tenure to encourage improvements. The imports and exports fluctuate considerably, as the following table shows:—

Year.	Imports.			Exports.		
	£	s	d.	£	s.	d.
1888	50,186	7	5	68,337	3	8
1890	29,560	3	8	45,492	6	2
1895	87,240	15	4	113,279	6	4
1899	73,314	17	9	71,315	17	5

No returns of revenue and expenditure are furnished by the Government, but the estimates provide for an annual expenditure of about £24,000, and there are neither debts nor a balance in the treasury. English, German, and American coinage is current, accounts being kept in dollars reckoned at four shillings. The wisdom of the late king in refusing to alienate an acre of land except upon lease has resulted in Tonga having been the last native state in the Pacific to lose its independence. In May 1900 the group became a British Protectorate under the native flag, the appointment of the consul and agent being transferred to the Government of New Zealand. There is a good code of law, drafted upon the model of the Indian Penal Code.

Tongking (in French, *Tonquin* or *Tonkin*), the northern division of the kingdom of Annam, forming an integral part of French Indo-China, extending 250 miles from north to south between 20° and 23° 20′ N., and 400 miles east to west between 102° and 108° E. The combined territories of Tongking and Annam form the "kingdom or empire of Annam." Actually, however, the protectorate of Tongking approaches nearer to direct administration than that of Annam proper, where the conditions of the protectorate are more closely observed. It is the court of Hué which appoints and recalls, subject to the approval of the governor-general, native officials, whose salaries are paid by the court. Formerly the king of Annam was represented in Tongking by a viceroy (*kinh-luoc*). Since 1897 this post has been abolished, and the Annamese officials are directly under the control of the Resident-General, who until 1891 was the chief personage of Indo-China. Cochin-China, however, held first rank for wealth and prosperity; but Tongking, with its population of about 12,000,000 and its situation on the southern frontier of China, must acquire great importance in the future. France is putting forth here her strongest effort towards colonization. The railway line from Hanoi to the Chinese frontier, *viâ* Phu-Lang-Thuong and Langson, will terminate at the Canton river. The great bridge, about ½ mile long, across the Red River at Hanoi has been completed. The Red River railway, which is to run to Yunnan, has been laid as far as Viétry, passing through Sontai. The lines from Hanoi to Haiphong and from Hanoi to Ninh-binh (to be prolonged to Hué) are under construction, and other lines are projected, including one from Tourane to Kwang-tri and Hué, and another between Hué and Saigon. Roads have been opened, and are maintained by the provinces through which they run; for example, those between Annam and Laos, lower Laos more especially. Important public works have been carried out, the docks at Haiphong enlarged, and canals deepened and opened. The imports of Tongking in 1900 were valued at £2,552,000. The local budget for 1901 was estimated to balance at £4,197,950 (revenue and expenditure).

Local Administration.—Local administration on a communal basis exists. The institution of the mandarinate remains intact. The vacancies are filled on a most democratic system, by means of selection. The primary school, in which the pupils learn only Chinese writing and the precepts of Confucius, stands at the base of this system. Then succeeds a half-yearly examination, by means of which are selected those eligible for the course of higher education given at the capital of the province in a school under the direction of a *doc-hoi*, or inspector of studies. Finally a great triennial competition decides the elections. The candidate whose work is notified as *très bien* is admitted to the examinations of the *dinh-thi*—which qualifies for the title of doctor and the holding of the highest offices. The note *bien* against a candidate gives him a second-class certificate entitling him to nomination as *phu*, prefect, or *huyen*, sub-prefect, as vacancies occur. The education of a mandarin includes local history, cognizance of the administrative rites, customs, laws, and prescriptions of the country, the ethics of Confucius, the rules of good breeding, the ceremonial of official and social life, and the practical acquirements necessary to the conduct of public or private business. Annamese learning goes no farther. It includes no scientific idea, no knowledge of the natural sciences, and is characterized by the most absolute ignorance of even the most rudimentary instruction conveyed in a European education. The complications of Chinese writing greatly hamper education. The Annamese mandarin must be acquainted with Chinese, since he writes in Chinese characters. But the character being ideographic, the words which express them are dissimilar in the two languages, and official text is read in Chinese by a Chinese, in Annamese by an Annamese. The very intricacy of these institutions conduces to their persistence. Chinese writing remains the only one in practical use. In other matters the mandarins have resigned themselves to the French régime. For several years, apart from the commercial and industrial movement which has so greatly developed in Tongking (and which includes the manufacture of matches, glass, and furniture, the spinning of cotton and silk, mother-of-pearl inlaying, &c.), a considerable agricultural movement has arisen. Plantations of coffee, cocoa, cotton, mulberry, &c., are making rapid progress. The chief towns, Hanoi, Haiphong, and Ninh-binh, have increased in population and extended their bounds. (See HANOI and HAIPHONG.)

The changes in Annam are in no sense as important, though Hué has increased. The total population is estimated at over 6,000,000, but there are very few Europeans. The port of Tourane, however, has become the centre of an important commercial movement and the town (a municipality) has a population of 100 French, 200 Chinese, and 4000 natives. Coal is worked in the district. The king of Annam, Prince Bua-Lan, was born in 1879 and proclaimed emperor under the title of Than-Thai on 31st January 1889, after the death of the emperor Ding-Khank three days before. Very active and open-minded, he has greatly modified the old Court customs and rendered himself accessible—whereas the king of former times was only to be seen from afar, in ceremonial ritual. He even visited the governor-general at Saigon in December 1897, and the Saigonese were privileged to behold the emperor of Annam riding on a bicycle. The local budget of Annam since the creation of a budget-general of Indo-China is somewhat straitened. It was estimated for 1901 at 2,081,416 piastres, receipts and expenditure. (See also COCHIN-CHINA and INDO-CHINA.) (J. M. A. DE L.)

Tonk, a native state of India, in the Rajputana Agency. It consists of six isolated tracts, some of which are under the Central India Agency. Area in Rajputana,

1415 square miles. Population (1881), 170,179; (1891), 198,934, showing an increase of 17 per cent.; average density, 141 persons per square mile. Population in Central India (1881), 167,850; (1891), 181,135. Population of both tracts (1901), 273,035. The gross revenue in 1896–97 amounted to Rs.17,01,237, of which Rs.3,10,000 was derived from loans. Of the expenditure, Rs.97,903 was directly devoted to famine relief, and Rs.39,000 to public works. No tribute is payable.

There were 13 schools, with 857 pupils. The chief, whose title is Nawab, is a Mahommedan of Afghan descent. The founder of the family was Amir Khan, the notorious Pindari leader at the beginning of the 19th century, who received the present territory on submitting to the British in 1817. The state is now well administered, the settlement of the land revenue and public works being each under a British official. The minister, Sahibzada Obeidullah Khan, C.S.I., was deputed on political duty to Peshawar during the Tirah campaign of 1897. A railway is now being constructed, with the help of a loan from Gwalior, in the outlying division of Chabra, on which 3740 persons obtained labour during the famine of 1896–97; and feeder roads are being made to railway stations in other parts of the state. Distress was again caused by drought in 1899–1900. The town of Tonk is situated 1462 feet above the sea, midway between Jaipur and Bundi, near the right bank of the river Banas. Population (1881), 40,726; (1891), 46,069; (1901), 38,641. It is surrounded by a wall, with a mud fort. It has a high school, the Walter female hospital, under a lady superintendent, and a hospital for males.

Tonnage.—The mode of ascertaining the tonnage of merchant ships is settled by the Merchant Shipping Acts. But before explaining the method by which this is computed, it is well to remark that there are several tonnages employed in different connexions. *Displacement tonnage* is that which is invariably used in respect of war-ships, and is the actual weight of water displaced by the vessel whose tonnage is being dealt with. Men-of-war are designed to carry all their weights, including coal, guns, ammunition, stores, and water in tanks and in boilers, at a certain draught, and the tonnage attributed to them is the weight of water which at that designed draught they actually displace. This displacement tonnage is therefore a total made up of the actual weight of the ship's fabric and that of everything that is on board of her. It can be found by ascertaining the exact cubic space occupied by the part of her body which is immersed (including her rudder, propellers, and external shafting) at the draught under consideration in cubic feet, and dividing this by 35, since 35 cubic feet of sea water weigh one ton. Of course there is nothing to prevent displacement tonnage from being used in describing the size of merchant ships, and indeed in regard to the performances of fast steamships on trial it is usual to give their draught on the occasion when they are tested, and to state what was their actual displacement under these trial conditions. But it is obvious, from what has been said as to the components which go to make up the displacement at load draught, that this tonnage must, in respect of any individual ship, be the greatest figure which can be quoted in regard to her size. It is usual for dues to be assessed against merchant vessels in respect of their *registered tonnage*. This must therefore be fixed by authority, and at present vessels are measured by the officer of customs according to the rules laid down in the second schedule to the Merchant Shipping Act, 1894. As will be seen from the explanation of the method adopted, this is a somewhat arbitrary process, and even the gross registered tonnage affords little indication of the actual size of the ship, whilst the under-deck and net tonnages are still less in accord with the extreme dimensions.

As to *length for tonnage*, the measurements start with the tonnage deck, which in vessels with less than three decks is the upper, and in vessels of three or more decks is the second from below. The length for tonnage is measured in a straight line along this deck from the inside of the inner plank at the bow to the inside of the inner plank at the stern, making allowance for the rake, if any, which the midship bow and stern timbers may have in the actual deck. When this is measured it is apparent into which of five classes the ship's tonnage-length places her. If she be under 50 feet in length she falls into the first class, while if she be over 225 feet in length she falls into the fifth class, the remaining three classes being intermediate to these. Vessels of the first class are measured as in four equal sections, and vessels of the larger class as in twelve equal sections, according to their length. Then at each of the points of division so marked off *transverse areas* are taken. This is done by measuring the depth in feet from a point at a distance of one-third of the round of the beam below the tonnage deck to the upper side of the floor timbers. Where the vessel has a ceiling and no water-ballast tanks at the point of measurement, $2\frac{1}{2}$ inches is allowed for ceiling. But where there are such tanks the measurement is taken from the top of the tank and no allowance is made for ceiling, whether there in fact be any or not. If the midship depth so found exceeds 16 feet, each depth is divided into six equal parts, and the horizontal breadths are measured at each point of division and also at the upper and lower points of the depth, extending each measurement to the average thickness of that part of the ceiling which is between the points of measurement. They are then numbered from above, and the second, fourth, and sixth multiplied by four, whilst the third and fifth are multiplied by two. The products are then added together. To the sum are added the first and the seventh breadths. This total having been multiplied by one-third, the common interval between the breadths, the resultant is the transverse area. The transverse areas so obtained at each point of the vessel's length are numbered from the bow aft. Omitting the first and last, the second and every even area so obtained are multiplied by four, whilst the third and every odd area are multiplied by two. These products are added together, as are also those of the first and last areas if they yield anything, and the figure thus reached is multiplied by one-third of the common interval between the areas. This product is reckoned as the *cubical capacity of the ship* in feet. When divided by 100 the result is the *registered under-deck tonnage* of the ship—subject to the additions and deductions ordered by the Act. Directions of a kind similar to those already set out are given whereby the tonnage in the space enclosed between the tonnage and upper decks may be ascertained, and also for the measuring of any break, poop, or other permanent closed-in space on the upper deck available for stores, and the sum of the capacity of these must be added to the under-deck tonnage to arrive at the *gross registered tonnage*. But an express proviso is enacted that no addition shall be made in respect of any building erected for the shelter of deck passengers and approved by the Board of Trade. In the process of arriving at the *net tonnage* the main deduction allowed from the gross tonnage is that of machinery space in steamships. The method of measurement here is similar to that by which the under-deck tonnage is reached. Where the engines and boilers are fitted in separate compartments, each compartment is measured separately, as is the screw shaft tunnel in the case of steamships propelled by screws. The tonnage of these spaces is reckoned, not from the tonnage deck, but from the crown of the space, whilst if it has previously been reckoned in the gross tonnage, there may be an allowance for the space above the crown, if enclosed for

the machinery or for the admission of light and air. Allowances are only made in respect of any machinery space if it be devoted solely to machinery or to light and air. It must not be used for cargo purposes or for cabins. Further, by the Act itself in the case of paddle steamships, where the machinery space is above 20 per cent. and under 30 per cent. of the gross tonnage, it is allowed to be reckoned as 37 per cent. of such gross tonnage; whilst similarly, in the case of screw steamships, where such machinery space is over 13 per cent. and under 20 per cent. of the gross tonnage, it is allowed to be reckoned as 32 per cent. Further deductions are also made in respect of space used solely for the accommodation of the master and the crew, and for the chart-room and signal-room, as well as for the wheel-house and chain cable locker and for the donkey-engine and boiler, if connected with the main pumps of the ship, and in sailing vessels for the sail locker. The space in the double bottom and in the water-ballast tanks, if these be not available for the carriage of fuel stores or cargo, is also deducted if it has been reckoned in the gross tonnage in the first instance.

From the rules above laid down it follows that it is possible for vessels, if built with a full midship section, to have a gross registered tonnage considerably below what the actual cubical capacity of the ship would give, whilst in the case of steam tugs of high power it is not unprecedented, owing to the large allowances for machinery and crew spaces, for a vessel to have a registered net tonnage of *nil*.

Suez Canal dues being charged on what is practically the registered tonnage (though all deductions permitted by the British Board of Trade are not accepted), it is usual, at all events in the British navy, for warships to be measured for what would be their registered tonnage if they were merchant ships, so that in case they may wish to pass through the Canal a scale of payment may be easily reached. But such tonnage is never spoken of in considering their size relative to other vessels.

Two other tonnages are also made use of in connexion with merchant ships, especially when specifications for vessels are being made. The first of these is *measurement capacity*. This is found by measuring out the true cubic capacity of the holds, whereby it is found what amount of light measurement goods can be carried. The second is *deadweight capacity*. This is generally given as excluding what is carried in the coal bunkers, and it is therefore the amount of deadweight which can be carried on the holds at load draught when the vessel is fully charged with coals and stores. (B. W. G.)

Tonnay-Charente. See ROCHEFORT.

Tönsberg, a fortified seaport town of Norway, county of Jarlsberg and Laurvik, situated on a bay on the south coast, near the entrance to Christiania Fjord, 72 miles by rail south by west of Christiania. It is one of the most ancient towns in Norway. It is now the headquarters of a sealing and whaling fleet (100 to 120 vessels of an aggregate of 10,000 tons), which employs approximately 2000 men. The principal industries are refineries for preparing whale and seal oil, and saw-mills. There is a trade of the yearly value of about £300,000. Tönsberg possesses a mercantile fleet of close upon 224,000 tons (over 150 vessels). Population (1885), 7034; (1891), 7215; (1900), 8620.

Toole, John Lawrence (1832– ——), English actor, was born in London, 12th March 1832. His strong leanings towards the stage led him to abandon a commercial career when he was twenty, and to make his first public appearance at a benefit performance at the Haymarket in July 1852. In this he was so successful that he obtained an engagement at the Queen's Theatre, Dublin, where he became popular. After other engagements at Belfast, Edinburgh, and Glasgow, he appeared in London, in 1854, at the St James's Theatre, in "low comedy" characters. His reputation grew rapidly, and when Webster undertook the management of the Adelphi in 1858, Toole was engaged as his leading comedian. It was about this time that he first met Henry Irving, and began a lifelong friendship with him. Some five years at the Adelphi were followed by engagements at the Queen's Theatre (where the company included Charles Wyndham, John Clayton, Henrietta Hodson, and Henry Irving) and the Gaiety. In 1874 Toole undertook an American tour with considerable success, and reappeared at the Gaiety in 1875. In 1879 he became manager of the Folly Theatre, which he subsequently re-christened (in 1882) Toole's Theatre, and managed it until severe ill-health compelled him to retire from the stage in the autumn of 1895. In 1890 he made a most successful tour through the Australian colonies. Besides a remarkable fund of drollery, exploited to the full in such parts as Paul Pry, Spriggins in *Ici On Parle Français*, or "Chawles," Toole's powers of acting always included a considerable command of pathos, as he showed in characters such as Caleb Plummer, Michael Garner in *Dearer than Life*, or Uncle Dick in *Uncle Dick's Darling;* while those who saw him in *Paw Clawdian* and *Stagedora* will have a delightful recollection of his talent for travesty. His last public appearance was made on 28th September 1895, at his own theatre.

Toowoomba, a town of Queensland, Australia, in the county of Aubigny, 76 miles by rail west by north of Ipswich. It is the centre of population for the pastoral and agricultural district of Darling Downs, which is occupied by a desirable class of settlers. A town hall, school of arts, theatre, and library were erected in 1900 at a cost of £10,000, and waterworks have been constructed. Vineyards are cultivated in the suburbs by a German colony numbering about 1000, and large quantities of wine are made. Altitude, 1960 feet. Mean temperature, year, 61° F.; January, 71·6°; July, 48·2°; rainfall, 45·63 inches. Population (1891), 7007; (1900), 9137.

Topeka, a city of Kansas, U.S.A., capital of Shawnee county and of the state, on the Kansas river, in the eastern part of the state, at an altitude of 886 feet. The city is regularly laid out on a fairly level site, is divided into six wards, has water-supply and sewerage systems, and its business streets are paved, mainly with brick and asphalt. It contains many fine buildings, among them the United States Government building, the capitol, the court-house, and several fine business blocks. There are five railways—the Atchison, Topeka and Santa Fé (which has offices and workshops here); the Chicago, Rock Island, and Pacific; the Leavenworth and Topeka; the Missouri Pacific; and the Union Pacific—which give the city a large traffic. In 1900 there were 399 manufacturing establishments, with a capital of $3,891,531. They employed 3758 hands, and the product had a value of $9,977,605. The chief industry is flour-milling, the product of which was $2,188,034. The assessed valuation of real and personal property was in 1900 $11,728,525, indicating a very low rate of assessment. The net debt was $922,040, and the rate of taxation was $46·00 per $1000. Topeka is the seat of Washburn College, a Congregational institution opened in 1865, which in 1899 had a faculty numbering 18 and

was attended by 228 students, 86 of whom were women. Population (1890), 31,007; (1900), 33,608, of whom 3201 were foreign-born and 4807 negroes.

Topelius, Zakris [or ZACHARIAS] (1818–1898), after the death of Runeberg by far the most prominent writer of Finland, was born at Kuddnäs, near Nykarleby, on the 14th of January 1818. He was the son of a doctor of the same name, who was distinguished as the earliest collector of Finnish folk-songs. Topelius became a student at Helsingfors in 1833, and remained connected with that university for the rest of his life, being made professor in 1863 and receiving in succession all the academic distinctions open to him. Quite early in his career, by the side of his constant tutorial and professional work, he began to distinguish himself as a lyrical poet, with the three successive volumes of his *Heather Blossoms* (1845–54). The earliest of his historical romances was *The Duchess of Finland*, published in 1850. He was active in journalism also, and was editor-in-chief of the *Helsingfors Gazette* from 1841 to 1860. In 1878 Topelius was allowed to withdraw from his professorial duties, which he began to feel irksome, but this did not sever his connexion with the university; it gave him, however, more leisure for his abundant and various literary enterprises. Of all the multifarious writings of Topelius, in prose and verse, that which has enjoyed the greatest popularity is his *Tales of a Barber-Surgeon*, episodes of historical fiction from the days of Gustavus II. Adolphus to those of Gustavus III., treated in the manner of Sir Walter Scott; the five volumes of this work appeared at intervals between 1853 and 1867. Topelius attempted the drama also, with most success in his tragedy of *Regina von Emmeritz* (1854). Topelius was not an exquisite, but a fresh, cheerful, and wholesome writer. He aimed, with eminent but perhaps pathetic success, at the cultivation of a strong passion of patriotism in Finland, and he is to be thought happy in that he did not live to witness the oppression of the noble and long-suffering nation which he had roused by his writings. He died on the 13th of March 1898 at Helsingfors. Among his many claims on the attention of Finlanders it must be added that Topelius was an exceptionally happy writer for children. His abundant poetry is graceful and patriotic, but does not offer any features of great originality.

(E. G.)

Topete, Juan Bauptista (1821–1885), Spanish naval commander and politician, was born in Mexico, 24th May 1821. His father and grandfather were also Spanish admirals. He entered the navy at the age of seventeen, cut out a Carlist vessel in 1839, became a midshipman at twenty-two, obtained the cross of naval merit for saving the life of a sailor in 1841, and became a lieutenant in 1845. He served on the West Indian station for three years, and was engaged in repressing the slave trade before he was promoted frigate captain in 1857. He was chief of staff to the fleet during the Morocco war, 1859, after which he got the crosses of San Fernando and San Hermenegildo. Having been appointed chief of the Carrara arsenal at Cadiz, he was elected deputy and joined the Union Liberal of O'Donnell and Serrano. He was sent out to the Pacific in command of the frigate *Blanca*, and was present at the bombardment of Valparaiso and Callao, where he was badly wounded, and in other engagements of the war between Chile and Peru. On his return to Spain, Topete was made port captain at Cadiz, which put him into a position to take the lead of the conspiracy in the fleet against the Bourbon monarchy. He sent the steamer *Buenaventura* to the Canary Isles for Serrano and the other exiles; and when Prim and Sagasta arrived from Gibraltar, the whole fleet under the influence of Topete took such an attitude that the people, garrison, and authorities of Cadiz followed suit. From that day Topete took part in all the acts of the Revolutionary Government, signed the proclamations, accepted the post of marine minister, was elected a member of the Cortes of 1869, supported the pretensions of Montpensier, opposed the election of Amadeus, sat in several cabinets of that king's reign, was prosecuted by the federal republic of 1873, and again took charge of the marine under Serrano in 1874. After the Restoration Topete for some years held aloof, but finally accepted the presidency of a naval board in 1877, and sat in the Senate as a life peer until his death on 29th October 1885 at Madrid. (A. E. H.)

Torda, a corporate town of Hungary, capital of the county of Torda-Aranyos, near the river Aranyos, 16 miles south-east of Kolozsvár. As a salt-producing district it was known to the Romans. It has still important salt mines and baths. It has a large public hospital, an old Unitarian church, an asylum supported by the Franciscans, and a large manufactory of cellulose. In its vicinity is the rocky formation known under the name of "Cleft of Torda," which crosses the calcareous mountain for 2 miles, presenting many romantic steep rocks and deep caves. Population (1891), 11,084; (1901), 12,117.

Toreno, Queipo de Llano y Gayoso de, COUNT (1840–1890), Spanish politician, was born in Madrid in 1840, and was the son of the Count de Toreno, who distinguished himself in the independence war against Napoleon, and afterwards as a historian, orator, minister, and statesman during the reigns of Ferdinand VII. and Isabella II. Young Toreno was educated at the Madrid Institute and University, entered Parliament in 1864 as a Moderado, and sat in all the Cortes of Queen Isabella's reign as a deputy for his ancestral province, Asturias. Loyal to the Bourbons all through the revolution, he nevertheless became a deputy in the Cortes of 1871–73, and founded an Alphonsist paper, *El Tiempo*, in 1873. When the Restoration took place, its first cabinet made Count de Toreno mayor of the capital, and in 1875 minister of public works, in which capacity he improved the public libraries, museums, academies, and archives, and caused many important works to be published, including the *Cartas de Indias*. In 1879 he became minister for foreign affairs, in 1880 president of the House of Deputies, in 1884 again governor of Madrid, and in 1885 again president of the House of Deputies. During the reign of Alphonso XII. and the first years of the regency of Queen Christina, Count de Toreno was one of the most prominent Conservative leaders, and was often consulted by the Crown. He died on 31st January 1890. He was a patron of the Turf, and established a racecourse in Madrid, where the first races took place in the reign of Alphonso XII. (A. E. H.)

Torgau, a town of Prussia, province of Saxony, 48 miles by rail east by north of Halle, on the left bank of the Elbe, here crossed by two iron bridges (one a railway bridge). The fortifications were dismantled in 1889. The town hall contains a collection of Saxon antiquities. In the vicinity is the royal stud farm of Graditz. Population (1885), 10,988; (1900), 11,811.

Toro, town of Spain, in the province and diocese of Zamora, on the right bank of the river Douro, 35 miles west by south of Valladolid. It has a station on the railway from Medina de Campo to Zamora. It has excellent and well-attended lay and ecclesiastical schools. There is a fine bridge of twenty-two arches across the Douro. The town is a picturesque assemblage of decaying palaces,

convents, narrow streets, public buildings, in part repaired in the 18th and 19th centuries. The cathedral church or abbey of Santa Maria la Mayor is considered older than, and quite as remarkable as, that of Zamora. It dates from the reigns of Alphonso VII. and Fernando el Santo. Toro has several fine parish churches and convents, palatial residences of the dukes of Alcañices, Fonsecas, Albas, and especially of the marquis of Santa Cruz, the last famous because the Cortes of 1371, 1442, 1505, that made Toro and its code of laws celebrated, were held there. Toro is first mentioned in documents of the 10th century, and its chequered history is intimately associated with that of the mediæval monarchies of Spain. Population (1897), 8421.

Törökszentmiklós, a large market town, situated on the great Alfold (plain), in the county of Jász-Nagy-Kun-Szolnok, Hungary, 60 miles south-west of Debreczen. On the extensive communal territory—81,695 acres—are produced immense quantities of wheat and other cereals. There is a large brick factory, a manufactory of ploughs, a steam-mill, and a considerable nunnery. Population (1891), 18,772; (1901), 21,881.

Toronto, the capital of the province of Ontario, and the second largest city in Canada, situated on the bay of the same name on the north shore of Lake Ontario, in 43° 39′ 25″ N. and 79° 23′ 39″ W. It is, next to Montreal, the principal railway centre in the Dominion, and has direct communication with all points of importance in British North America and the northern United States by way of the main lines and the branches (seven in number) of the Grand Trunk and Canadian Pacific railways. An electric street railway, with a track of 87 miles within the city limits, affords rapid and easy communication with all parts of the city, and, by connecting lines and extensions, with the neighbouring towns. During the season of navigation several lines of steamers run between Toronto and the principal ports on the Great Lakes and the St Lawrence. It is the seat of the provincial government, and contains the official residence of the lieutenant-governor, the parliament and departmental building, courts of law, offices of the department of education, and Toronto University. The new parliament and departmental building is situated in the centre of a finely-wooded park of upwards of 30 acres. It is in the Neo-Greek style, with the central portion, containing the legislative chamber, standing forward, bold and massive. The city hall and court-house, completed in 1900 at a cost of upwards of $2,500,000, is one of the finest civic buildings in North America. It is in the Romanesque style, and has a total length of 290 feet and a depth of 275 feet. It accommodates all the civic, county, police court, high court, and school board officials. Toronto is the centre of the wholesale trade of Ontario, and the seat of many flourishing industries, including extensive iron foundries, rolling mills, breweries, distillery, agricultural implement works—the largest employing 1500 men—stove, shoe, carpet, bicycle, rubber, and musical instrument factories, shipbuilding, &c.

The city occupies an area of 16·2 square miles, exclusive of the harbour and the island of the same name. It has 260 miles of streets, 233 miles of sewers, and 260 miles of water-mains; the water-supply, drawn through a conduit from an intake in deep water in Lake Ontario, is pumped by engines with a capacity to treat 42,000,000 gallons per day to a large reservoir in the northern part of the city. In 1902 there were 207 places of worship, in addition to upwards of 50 buildings and rooms used as missions; there were 59 public schools with 682 teachers, including 126 on the kindergarten staff, attended by 34,863 pupils, and annual expenditure $539,910; also 21 separate Roman Catholic schools, with 103 teachers and 5227 pupils. For secondary education there were 3 collegiate institutes, with 1400 pupils. The city contains the head offices of 9 banks—the Toronto, Commerce, Imperial, Dominion, Nova Scotia, Ontario, Standard, Sovereign, and Traders—with an aggregate paid-up capital of more than $22,000,000; of 37 loan companies, with nearly $21,000,000 of paid-up capital; and of the principal trust and insurance companies doing business in the province. The exports for 1894 were $3,984,462; 1900, $9,506,911; imports for 1894, $17,731,843; 1900, $31,787,053; duty paid in 1900, $5,363,816; bank clearings, 1892, $326,564,322; 1901, $625,228,306; gross assessment, 1902, $157,915,397; exemptions, $23,949,850; net assessment, $133,965,547; taxation, $2,612,328. The population in 1881 was 86,415; in 1883 the suburb of Yorkville was annexed, and subsequently Leslieville, Seaton, Brockton, and Parkdale were brought within the city limits; in 1891 it had increased to 181,220, and in 1901 to 208,040. The city returns four members to the Dominion House of Commons, and four to the provincial legislature. It is the seat of an Anglican bishop and a Roman Catholic archbishop. (J. Wh*.)

Torpedo.—In 1805 Robert Fulton demonstrated a new method of destroying ships by exploding a large charge of gunpowder against the hull under water. No doubt then remained as to the effectiveness of this form of attack when successfully applied; it was the difficulty of getting the torpedo, as it was called, to the required position which for many years retarded its progress as a practical weapon of naval warfare. Attempts were first made to bring the explosive in contact with the vessel by allowing it to drift down to her by the action of tide or current, and afterwards to fix it against her from some form of diving boat, but successive failures led to its restriction for a considerable period to the submarine mine, in which the explosive is stationary and takes effect only when the ship itself moves over or strikes the charge. Used in this way, it is an excellent deterrent to hostile warships forcing a harbour.

Spar or Outrigger Torpedo.—The limitations attached to the employment of submarine mines, except for coast defence, revived the idea of taking the torpedo to the ship instead of waiting for the latter to gain some exact point which she might very possibly avoid. This first took practical shape in the spar or outrigger torpedo. If the boat using it was not discovered and disabled while approaching, the chances were favourable to success and escape afterwards. Against a vigilant enemy it was doubtless a forlorn hope, but to brave men the venture offered considerable attractions.

Frequent use of this spar or outrigger torpedo was made during the American Civil War. A notable instance was the destruction of the Confederate ironclad *Albemarle* at the end of October 1864. On this mission Lieutenant Cushing took a steam launch equipped with an outrigger torpedo up the Roanoke river, in which lay the *Albemarle*. On arriving at the ship Cushing found her surrounded by logs, but pushing his boat over them, he immersed the spar and exploded his charge in contact with the *Albemarle* under a heavy fire. Ship and launch sank together, but the gallant officer jumped overboard, swam away, and escaped. Submerged boats were also used for similar service, but usually went to the bottom with their crews. During the war between France and China in 1884 the *Yang Woo* was attacked and destroyed by an outrigger torpedo.

Loconotive Torpedoes.—Though the spar torpedo had scored some successes, it was mainly because the means of defence against it at that time were inefficient. The ship trusted solely to her heavy gun and rifle fire to repel the attack. The noise, smoke, and difficulty of hitting a small object at night with a piece that could probably be discharged but once before the boat arrived, while rifle bullets would not stop its advance, favoured the attack. When a number of small guns and electric lights were added to a ship's equipment, success with an outrigger torpedo became nearly, if not entirely, impossible Attention was then turned in the direction of giving motion to the torpedo, and steering it to the required

point by electric wires worked from the shore or from another vessel; or, dispensing with any such connexion, of devising a torpedo which would travel under water in a given direction by means of self-contained motive power and machinery. Of the former type are the Lay, Sims-Edison, and Brennan torpedoes. The first two—electrically steered by a wire which trails behind the torpedo—have insufficient speed to be of much practical value, and hence are little used. The Brennan, since its adoption by the British Government for the defence of harbours and channels, has been developed and improved, especially in speed, which is now over twenty knots. Hence its superiority over other forms of controlled torpedo. It has the defect of all the species, that of possessing a very limited effective radius—much less than the range of modern guns—which consequently confines its use to narrow waters.

Uncontrolled Torpedoes (the Howell).—The objection of naval officers to have any form of torpedo connected by wire to their ship during an action, impeding her free movement, liable to get entangled in her propellers, and perhaps exploding where not desired—disadvantages which led them to discard the Harvey towing torpedo some years ago—has hitherto prevented any navy from adopting a controlled torpedo for its sea-going fleet. The last quarter of the 19th century saw, however, great advances in the equipment of ships with locomotive torpedoes of the uncontrolled type. The Howell may be briefly described as one of American origin, and has been placed in the armament of some of the warships of the United States: it has also a special feature of some interest. In this—as in all uncontrolled torpedoes—there is no attempt to steer it after entering the water, but the same direction is preserved throughout the run, allowance being made for the movement of the object at which it is directed. Motive power is provided in the Howell by causing a heavy steel fly-wheel inside the torpedo to revolve with great velocity previous to discharging the torpedo. This is effected by a small special engine outside operating on the axle. When sufficiently spun up, the axle of the fly-wheel is connected with the propeller shafts and screws which drive the torpedo, so that on entering the water it is driven ahead and continues its course until the power stored up in the fly-wheel is exhausted. The speed, therefore, is continually diminishing, but special mechanism has been devised to enable a uniform rate of progress to be maintained. A controlling apparatus keeps the torpedo from diving or coming to the surface, thus preserving a fixed depth throughout the run. Now when a torpedo is discharged into the sea from a ship in motion, it has a tendency to deflect owing to the action of the passing water. The angle of deflection will vary according to the speed of the ship, and is also affected by other causes, such as the position in the ship from which the torpedo is discharged, and its own angle with the line of keel. Hence arise inaccuracies of shooting; but these do not occur with this torpedo, for the motion of the fly-wheel, acting as a gyroscope—the principle of which applied to the Whitehead torpedo is described later—keeps this torpedo on a straight course. This advantage, combined with simplicity in construction, induced the American naval authorities at one time to contemplate equipping their fleet with this torpedo, for they had not, up to within a few years ago, adopted any locomotive torpedo. A great improvement in the torpedo devised by Mr Whitehead led them, however, definitely to prefer the latter, and to discontinue the further development of the Howell system.

Whitehead Torpedo.—Almost every year chronicles some advance in this wonderful piece of mechanism. The outward form is now somewhat different from that originally adopted. In place of a sharply-pointed head—believed at one time to be necessary for speed—the foremost compartment is now made much fuller, which not only adds to the speed, but allows of double the amount of explosive being carried with the same length and diameter of torpedo. All are now made with this bluff head or nose. This modification, with increased efficiency in the Brotherhood three-cylinder air engine, has enabled a speed of 30 knots for a short range to be attained. This is with a torpedo of 14 inches diameter. For a longer range a larger weapon must be employed capable of carrying a greater supply of air. To obtain this, torpedoes of 18 inches diameter, involving increased length and weight, have for some time been constructed, and have taken the place of the smaller torpedo in the equipment of warships. This advance in dimensions has not only given a faster and steadier torpedo, but enabled such a heavy charge of gun-cotton to be carried that its explosion against any portion of a ship would inevitably either sink

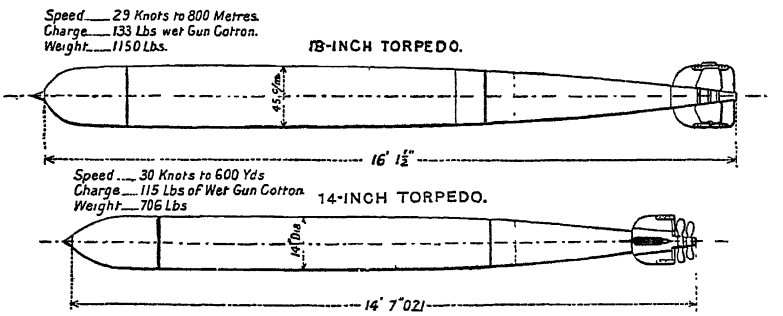

FIG. 1.—Diagrams of 14 and 18 inch Torpedoes.

or disable her. The dimensions, shape, &c., of the present 14 and 18 inch torpedoes are shown in Fig. 1. The defect of the Whitehead torpedo hitherto had been that a very limited range was imposed by the uncertainty of its course under water. The speed of the ship from which it was discharged, the angle with the keel at which it entered the water, and the varying velocity of impulse, tended to error of flight, such error being magnified the farther the path of the torpedo was prolonged. Hence 600 yards was considered the limit of distance within which the torpedo should be discharged at sea against an object from a ship in motion.

In these circumstances, though improvements in the manufacture of steel and engines allowed of torpedoes of far longer range being made (the fastest torpedo up to 1898 having a speed of 29 knots for 800 yards), it was of no advantage to make them, as they could not be depended upon to run in a straight line from a stationary point for more than 800 yards, while from a ship in motion good practice could only be ensured at a reduced range. It was obvious, therefore, that to increase the effective range of the torpedo, these errors of direction must be overcome by some automatic steering arrangement. Several inventors have turned their attention to the subject since 1885, nearly all of whom proposed to utilize the principle of the gyroscope for the purpose. The first which gave any satisfactory results was an apparatus devised by Mr Ludwig Obry—an engineer in Austria—and tried by the Italian Government about 1896. These trials demonstrated the feasibility of accurately and

automatically steering a torpedo in a direct line by this means. Messrs Whitehead and Co. of Fiume then acquired the invention, and after exhaustive experiments produced the apparatus which is now fitted to every torpedo made. It is based on the principle that a body revolving on a free axis tends to preserve its plane of rotation. A gyroscope with plane of rotation parallel to the vertical axis of the torpedo will have an angular motion if the torpedo is diverted from its original course. This angular motion is employed to actuate the steering mechanism by operating an air motor connected with the rudders, and keeping the torpedo in the line of discharge. The apparatus consists of a fly-wheel caused to rotate by a spring, the barrel on which the latter is wound having a segmental wheel which gears into a toothed pinion spindle of the fly-wheel. Owing to the diameter of the segment being much greater than the pinion, a rapid rotatory motion is imparted. The spring is wound up by a key from outside the torpedo, and kept in tension until the projectile is discharged, when the spring is released by the air lever being thrown back, which admits air to the engine; the gyroscope is then freed and set in motion with its plane in the plane of the vertical axis of the torpedo as it was in the launching tube.

Assuming now that the course of the torpedo is diverted by any cause, its axis will move or perform a certain angular motion with regard to the plane of the fly-wheel, which will have the same result as if we consider the conditions reversed, *i.e.*, as if the plane of rotation of the fly-wheel were altered and that of the axis of the torpedo remained the same. The axis of the fly-wheel performs a relative angular motion which it imparts to a crank actuating a servo-motor worked by compressed air, and connected with the rudders of the torpedo, moving them in the opposite direction to that in which the torpedo was diverted from its original course. Thus all inaccuracies of flight due to errors of adjustment, miscalculation of deflection, or even damage to some part, are eliminated. As long as the gyroscope is in good order the torpedo is bound to run in the line it was pointing when the fly-wheel was started. But the gyroscope can do more. By suitable adjustment the torpedo can be made to turn to any given angle from the direction of discharge, and then run in a straight line. For instance, when discharged from a tube fixed right ahead, the torpedo can be made, by means of the gyroscope, to travel in a new direction on either side; or supposing it be desired to fire ahead from a broadside tube which does not traverse sufficiently in that direction, the object can be attained by means of this apparatus. It is placed in the after body of the torpedo, as indicated in Fig. 2.

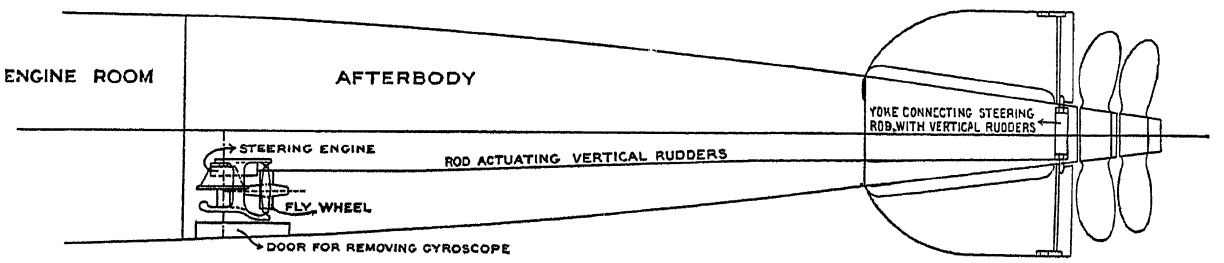

FIG. 2.—Arrangement of Gyroscope in Torpedo.

The efficiency of the Whitehead torpedo has thus been enormously increased, and more accurate practice can now be made at 2000 yards than was formerly possible at 800 yards. This adds considerably to the chances of torpedo-boats attacking ships, even in daytime, at sea or at anchor, and will render further protection necessary against this weapon. Against a ship in motion there is still, however, the calculation as to her speed, and the distance she will travel before the torpedo reaches her. Should this be miscalculated, an increased range for torpedoes will magnify the error. For instance, a 30-knot torpedo will travel 1000 yards in a minute. If aimed at a ship on the beam assumed to be steaming 15 knots an hour, to reach her when 1000 yards distant the torpedo must be discharged at a point 500 yards ahead of her. But if the ship is actually steaming 12 knots, she will have travelled only 400 yards in the minute, and the torpedo will be 100 yards in advance of her. If discharged at a range of 500 yards, such a miscalculation causes an error of only 50 yards or 150 feet. But if the object is 300 feet long, and her centre was taken as the target, her bow would be just at the spot the torpedo would reach in thirty seconds. It would seem, therefore, that increased velocity of torpedo is necessary before the full advantages of the gyroscope can be realized. To attain this, higher pressures of air are sought, and experiments are being carried out with nickel-steel air-chambers, by which, without increasing their weight, they can safely stand a greater working pressure. Longer-range torpedoes are, however, being adopted by most nations. The following dimensions of torpedoes made by Messrs Whitehead for Japan will show what has been done in this direction:—

Length	21 feet 4 inches.
Diameter	17·7 inches.
Weight complete	1968 lb.
Weight of explosive	198 lb.
Pressure of air	2250 lb on square inch.
Speed for 2000 metres (2187 yards)	28 knots.
Speed for 1000 metres (1094 yards)	31 knots.

Torpedo Carriages and Discharge.—As no gun which is inefficiently mounted can give good results, so the best torpedo is valueless without a good carriage or system of discharge. In the early days of the Whitehead, discredit came upon it because the importance of this was not sufficiently realized; and an erratic course under water was in nine cases out of ten due to a crude method of discharge. A delicate piece of mechanism was dropped into the water from a height of several feet, and naturally suffered internal derangement. Gun-ports were then used for the purpose, but now a special orifice is made, to which the torpedo carriage is fitted with a ball-and-socket joint—forming a water-tight aperture—so that this carriage or tube may be only 2 or 3 feet above the water-line. The ball-and-socket joint enables it also to have a considerable angle of training. Originally the torpedo was pushed out by a rod acted upon by compressed air, in which case the carriage was a simple frame. The rod, pressing against the tail with some force, was apt to damage or disarrange the rudders, so the air-gun took the place of rod impulse. Here the torpedo fits closely in a tube or cylinder with an opening at the rear made air-tight when closed. At the

desired moment compressed air is admitted to the rear part of the cylinder and blows the torpedo out. Gunpowder then superseded air for this operation; and now this has given place to a small charge of cordite, which does not leave any deposit on the inside of the cylinder. There is a double risk in the use of locomotive torpedoes from above water. (1) The charge may be exploded by hostile fire. Though mainly consisting of damp gun-cotton, which is not readily ignited, the dry primer and detonator may be struck, which would lead to a disastrous explosion. (2) The air-chamber is also a source of danger. As it contains air compressed to a high degree of tension, experiments have shown that if struck by a small shell it may burst with great violence; and as it offers a considerable mark, this is not an improbable event in an action. An instance of the danger of above-water torpedo tubes occurred in the Spanish–American war at the battle of Santiago. A shell entered the *Almirante Oquendo* and struck a 14-inch torpedo in the tube. The charge detonated, causing a fearful explosion and practically wrecking that part of the vessel. The development of moderate-sized quick-firing guns has increased this risk. Hence we find the use of above-water torpedo tubes diminishing, and in time this method of discharge will probably be employed only in special torpedo craft and such vessels as afford armour defence to positions where these weapons are located.

Submerged Discharge.—The risk attached to having loaded torpedoes above the water-line—independently of the fact that to get the best result they should start in the element to which they belong—has given great impetus to the system of submerged discharge. From the earliest days of the weapon this has been employed to some extent. But it was principally in the direction of right-ahead fire, by having an orifice in the stem of the ship under water, to which a torpedo tube was connected. The tactical idea was thus to supplement attack with the ram, so that if the vessel endeavouring to ram saw that the object would

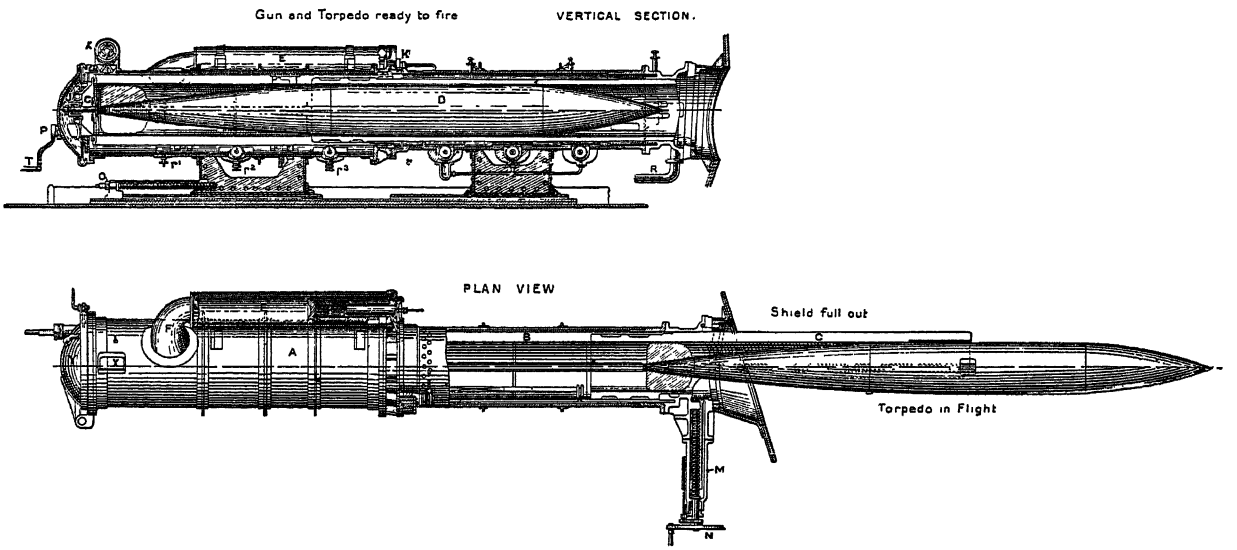

FIG. 3.—Broadside submerged 18-inch Torpedo Tube.

evade this attack, she could project a torpedo ahead, which, travelling faster than the vessel, might as effectually accomplish the required service. The stem orifice had a watertight cover, which was removed on the torpedo being placed in the tube and the inner door closed; then, sufficient impulse being imparted to eject the torpedo, and its machinery being set in motion at the same time, it darted forward towards the enemy. There is, however, some risk of the ship using a torpedo in this manner striking it before the missile has gathered the necessary impetus from its propellers to take it clear of the vessel. The system, moreover, has the disadvantage of weakening the ram, the construction of which should be of immense strength. There is the further liability of ramming with a torpedo in the bow tube, which would be as disastrous to friend as foe. This method of submerged discharge has therefore given place to ejecting the torpedo from the broadside. Considerable difficulty attached to getting the torpedo clear of the ship from this position without injury, especially when the vessel was proceeding at speed. The natural tendency of the passing water acting on the head of the torpedo as it emerged was to give a violent wrench and crush the rear end before that portion could clear the aperture. To prevent this the torpedo must be held rigid in the line of projection until the tail is clear of the ship. This is thus effected. Besides the tube with aperture in side of the ship under water, fitted with sluice-valve, all broadside submerged discharge apparatus possess the following features: A shield is pushed out from the ship's side. In this shield there are grooves of some form. Guides on the torpedoes fit and run in these grooves. When discharged the torpedo is thus supported against the streams of passing water, and guided so that its axis continues in the line of projection until the tail is clear of the side, the shield being of such length that this occurs at the same time that the guides on the torpedo leave the grooves in the shield. An apparatus on this principle has been fitted to a number of ships of the British navy, and gives good results at high rates of speed. It has the defect that the shield must be run out previous to the torpedo being discharged, and brought back afterwards, thus involving three separate operations, each performed by compressed air.

In the broadside submerged discharge, designed, constructed, and supplied to many foreign navies by Messrs Armstrong of the Elswick works, the three operations are combined in one. There is an outer tube as before, but it contains an inner tube carrying the torpedo. Fixed to this tube, and prolonging it, is the shield fitted with grooves. Both tubes have a door at the rear—made air-tight when closed—by which the torpedo is entered. A charge of cordite is used for ejection instead of compressed air, the gas from which entering the outer cylinder first forces the inner tube out, and then by means of a valve in the door of the inner tube passes in and blows out

water and torpedo together, the shield supporting the latter until the tail is clear of the ship. By this time the cordite gas has expanded and cooled so as to relieve the pressure in rear; this causes the pressure of the water outside to push the shield and tube into the ship again, so that practically the whole operation is one motion.

Fig. 3 will further explain this apparatus. A is the outer tube; B the inner tube; C the shield; D torpedo; E explosion chamber for cordite charge placed at K; F pipe for gas to pass into outer tube; G and Y doors of inner and outer tube; J the valve which opens automatically when inner tube arrives at position shown in Fig. 2; T and P appliance for running the tube in and out by hand when desired; O arrangement for bringing whole apparatus back for repair, &c.; M and N sluice-valve and handle; R, r^1, r^2, r^3, for draining tubes before torpedo is put in; X indicator showing position of inner tube.

Torpedoes have been discharged from this apparatus with successful result from a ship steaming at 17½ knots.

The advantage of cordite over compressed air for impulse is that it requires no attention: when a charge is placed in the explosion chamber, and a torpedo is in the tube, all is in readiness for firing when desired, without further attention in the torpedo-room. The cordite is fired by electricity from the conning-tower; the officer, therefore, having ascertained that all is ready below, has only to press a button when the object is in the required position. Automatic indications are given in the conning-tower when the sluice-valve is opened and when all is in readiness for firing.

This method of discharging torpedoes from the broadside under water eliminates the principal danger of the system, which required the shield to be put into position beforehand. It was then liable to be struck and distorted by passing wreckage without the fact being apparent to those in the ship. On the discharge of a torpedo its course might thus be arrested, or possibly the charge be prematurely exploded in dangerous proximity to its own ship. There was a risk of getting the shield out too soon, and thereby exposing it unduly to injury, or leaving the operation until too late. The tendency of naval equipment being towards complication, any readjustment which makes for simplicity cannot be otherwise than beneficial, and this feature is especially desirable in all matters connected with the use of torpedoes.

The compartment containing the broadside submerged apparatus usually extends across the ship, so as to contain a tube for each side. In the largest ships it is now customary to have two compartments—one forward and the other aft—for this part of the armament, with a pair of tubes in each; while above-water tubes are being given up where interior space will admit of a submerged discharge.

Use in War.—It is difficult to say what place the Whitehead torpedo will take in the next great naval war, and whether it is destined to fulfil those expectations which the expenditure allotted everywhere to this branch would seem to warrant. This generation believes it has found in the torpedo a most potent weapon with which the biggest vessels may be sunk, or rendered harmless, besides possessing the further great advantage that it can be taken into action on small and inexpensive constructions. Hence the great development of the torpedo-boat all over the world. Since the locomotive torpedo was adopted as a weapon of naval warfare, however, it has scored successes only when used in connexion with craft specially constructed for its use. Though the armament of all battleships and cruisers is not considered complete without an installation of Whitehead torpedoes, there is no instance of either suffering injury from one of their own class employing this weapon in recent wars. At the battle of Yalu, between the Chinese and Japanese fleets, torpedoes were discharged by the former, but none took effect. The Japanese trusted solely to gun-fire. In the war between Spain and the United States the inferiority of Admiral Cervera's squadron to that under Admiral Sampson might at the battle of Santiago have been to some extent counterbalanced by a skilful and vigorous use of torpedoes. If, instead of striving only to escape, a bold dash had been made for the American ships, the Spanish cruisers rapidly approaching end on to the foe, enveloped in the smoke of their own guns, should—some at least—have got within torpedo range without fatal injury. Closing each other at a speed of 10 knots only, they would cover an interval of 6000 yards in 9 minutes—a short time in which to disable a ship by gun-fire under such conditions. But Cervera elected to offer a passive resistance only, and while suffering destruction wrought no material injury upon his opponents. On the other hand, there have been several instances of large warships being sunk by locomotive torpedoes discharged from small craft. During the Chilian revolutionary war of 1891, a battleship, the *Blanco Encalada*, of 3500 tons, was attacked in Caldera Bay by two torpedo vessels—the *Lynch* and *Condell*—of 750 tons. They entered the bay at dawn, the *Condell* leading. This vessel fired three torpedoes which missed the ironclad; then the *Lynch*, after one ineffective shot, discharged a second torpedo, which struck the *Blanco* on the side nearly amidships. The latter had opened fire with little result, and sank soon afterwards. A similar incident occurred in 1894, when the Brazilian ironclad *Aquidaban* was sunk in Catherina Bay by the *Sampaio*—a torpedo vessel of 500 tons. She entered the bay at night, and first discharged her bow torpedo at the ironclad, which missed; she then fired a broadside torpedo, which struck and exploded against the bow of the *Aquidaban*. It caused a great shock on board, throwing an officer on the bridge into the water. The vessel sank soon afterwards, and the *Sampaio* escaped uninjured.

After the defeat of the Chinese at sea, their remaining ships took refuge in the harbour of Wei-hai-wei. Here they were blockaded by the Japanese fleet, which, having a number of torpedo-boats, made several determined attacks upon the ships inside. After one or two attempts, foiled by the obstructions placed by the Chinese to bar the passage, the Japanese boats succeeded in torpedoing several ships, and thus expedited the reduction of the place.

Effect upon Naval Tactics; Blockade.—It has often been assumed that steam and the torpedo-boat will in future render blockade impossible as it was carried out in the old wars; that, no longer dependent upon the wind to allow egress from the blockaded port, a vessel using steam can emerge when she chooses, while fear of torpedo attack will deter a blockading squadron from keeping such watch as to foil the attempt. As regards the power conferred by steam, it will be no less advantageous to a blockading squadron, enabling it to maintain its position, whereas sailing ships were often driven by gales to leave their station and seek a port. This gave opportunities for the blockaded vessels to escape. As regards torpedo-boats, they would no doubt be a danger to a blockading squadron unprovided with a means of defence against these craft. Such defence consists in an adequate number of small vessels interposing an in-shore squadron between the port and the main body outside. Thus they perform the two-fold service of watching the enemy's movements within and frustrating a torpedo attack.

The battleships of a squadron adequately provided in this respect would not require to remain close to a port; but, having a chain of communication with the advanced flotilla, its guard would be no less effective. As an instance of blockade under modern conditions, we have that of Admiral Sampson upon Santiago—a guard more rigidly maintained than any in the old wars. So little was he deterred by the knowledge that Admiral Cervera had two torpedo vessels in his force, that he drew his squadron closer in at night, when an attack might be expected, actually illuminating the entrance of the harbour with his electric search-lights, so that no craft could come out unperceived. No attempt was made to dislodge him from that position, and we may perhaps assume that blockade, if required in any scheme of naval strategy, will be carried out, whatever the weapons of warfare.

As regards the effect of torpedoes upon tactics at sea, and in general, as well as single ship, actions, they must operate against close range and employment of the ram. If it is recognized that a vessel within 800 yards—the effective radius of the torpedo—is liable to a fatal blow, she will endeavour in ordinary circumstances to keep outside that distance and rely upon gun-fire. The exception would be where she is overmatched in that respect, and hence might endeavour to restore the balance by the use of torpedoes. In a fleet action the danger of missing the foe and hitting a friend would restrict the discharge of torpedoes; and this risk increases as formations disappear. But the torpedo must be conceded a tactical superiority over the ram for the following reasons. A vessel to use the latter must come within torpedo range, while her adversary may successfully apply torpedoes without placing herself in any danger of being rammed. The ram can only be used in one direction, and a small miscalculation may cause disaster. If a vessel has more than one position from which torpedoes can be discharged, she is not confined as regards attack to a single bearing or direction.

In action we may consider the speed of the torpedo as double that of the ship, and since against a moving object allowance must be made for the space traversed while ram or torpedo is travelling towards it, the faster weapon is less affected in its chance of successful impact by change of direction and speed of the object at the last moment. Lastly, with machinery disabled a ship is powerless to use the ram, but can avert a ram attack with her torpedoes. The movements of squadrons or single ships c... entering an action are not likely to be influenced by any contemplated immediate use of torpedoes, for the gun must remain the primary weapon, at any rate at the first onset. Commanders would hardly risk being crushed by gun-fire before getting within torpedo range. Having faith in the efficiency of their ordnance and the gunnery skill of their crew, they would first manœuvre to bring these into play. Tactics for torpedo attack in such circumstances have not therefore been laid down, and it is only necessary to consider the positions which are advantageous for the use of this weapon, and, conversely, what should be avoided when a vessel, finding herself overmatched in gunnery, seeks to redress the balance with torpedoes.

Size of Target.—This, with a ship, varies in length as the torpedo approaches end on to the vessel, or at angle to the line of keel; the greatest being when the path of both forms a right angle. Hence the object is to place your ship where it presents the former condition to the enemy, while he affords the larger target. It must be remembered that, owing to the comparatively slow velocity of the torpedo, it must be aimed not directly at a ship in motion—like a shot from a gun—but at a point ahead which the ship will reach after the torpedo has traversed the intervening distance. Thus speed of object has to be estimated, and hence the importance of adding to the velocity of the torpedo and getting a broadside shot so as to reduce as much as possible errors of calculation. The great increase of the dimensions of warships, especially in length, which now has reached and exceeded 400 feet, adds to the chances of a successful hit with torpedoes, and will doubtless tend to diminish a desire in future naval tactics to close inside torpedo range for the purpose of ramming.

Range.—Though the effective range of a torpedo is fixed at 800 yards, it does not follow that ships must be within that distance of each other before this weapon comes into play. At certain bearings the object will be considerably outside this distance at the moment of discharge; but if approaching, and her course remain unaltered, she will reach a point within 800 yards of the spot from which the torpedo started. In the interval her enemy will also have traversed a certain distance, so that the two may never come within 1000 yards of each other. It thus follows, as stated, that a ship cannot ram without liability to torpedo attack, whereas it is possible to disable or sink with torpedo without risk of being rammed.

Taking range and size of target together, the most advantageous position is to be on the bow of the enemy while he bears abaft your beam. Thus situated, he is exposed to your broadside and quarter discharges, while by working the helm so as to turn your stern to him you diminish his target and increase the distance his bow torpedo has to run before it can overtake you. Thus a high speed of ship enables her to attain the most advantageous position, and renders more difficult the counter attack with the same weapon.

Finally, by improvements in construction and methods of discharge the torpedo has recovered the place it was rapidly losing a few years ago. As armour receives increased resisting power to above-water projectiles, and gets on a level again with the gun, more attention will be given to under-water attack, against which no adequate protection has yet been devised. Thus we shall probably find the torpedo taking a very prominent place in any future war between the great maritime Powers.

(S. M. E.-W.)

Torquay, a municipal borough (1892) and watering-place in the Torquay parliamentary division of Devonshire, England, on the north side of Tor Bay, 215 miles west-south-west of London by rail. A commission of the peace was granted to the borough in 1893. The harbour has been extended by the corporation at a cost of £90,000. The drainage has been efficiently carried out at a cost of £70,000, the water-supply improved at a cost of upwards of £150,000, and electric light introduced (1898) by the corporation. Modern erections are a church and the Princess pier and groyne. The hospital has been enlarged. Area, 1465 acres. Population (1891), 25,534; (1901), 33,625.

Torre Annunziata, a town of the province of Naples, Campania, Italy, on the east side of the Bay of Naples, and at the south foot of Mount Vesuvius, 14 miles south-east of Naples by rail. It has a royal arms factory and other iron-works, considerable manufacture of macaroni, breeding of silkworms, and some fishing and shipping. The harbour is protected by moles, and in 1897 was cleared by 1585 vessels of 194,889 tons. Population (1881), 20,829; (1900), about 26,000.

Torre del Greco, a town of the province of Naples, Campania, Italy, on the east shore of the Gulf of Naples, and at the south-west foot of Mount Vesuvius, 8

miles south-east of Naples by rail. It has shipbuilding yards and lava quarries. The inhabitants play a prominent part in the coral fishing off the African and Sicilian coasts, and coral is worked in the town, the workers being partly trained in a technical school. There is also fishing for tunny, sardines, and oysters. Further, hemp is woven and wine made. Population (1881), 21,588; (1900), about 25,000.

Torredonjimeno, a town of Spain, province of Jaen, to the north of Martos, on the river Salado de Porcuna, on the railway from Puente Jenil to Linares. It has fine squares, broad streets, a large parish church, town hall, several convents, and modern schools. The neighbourhood produces good wine, oils, wheat, and fruit. Population (1887), 9399; (1897), 10,370.

Torrens, Sir Robert Richard (1814–1884), British colonial statesman, was born at Cork, Ireland, in 1814, and educated at Trinity College, Dublin. He went to South Australia in 1840, and was appointed collector of customs. He was in this capacity an official member of the first Legislative Council, and in 1852 filled the position of Treasurer and Registrar-General. When responsible government was established he was elected as a representative for Adelaide and became a member of the first Ministry. In 1857 he introduced his famous Real Property Act, which he contended would render the transfer of land as simple in method as the transfer of vessels. The principle of the Act consists of conveyance by registration and certificate instead of deeds. The system was rapidly adopted in the other colonies and elsewhere, and was expounded by the author during a visit to the United Kingdom in 1862–64. After finally leaving South Australia, Sir R. R. Torrens represented Cambridge in the House of Commons from 1868 to 1874. In 1872 he was knighted in recognition of the benefits attending the operation of his Real Property Act wherever it had been introduced. He was the author of works on the effect of the gold discoveries on the currency, and other subjects. He died 31st August 1884.

Torrens, William Torrens M'Cullagh (1813–1894), English politician and social reformer, son of James M'Cullagh (whose wife's maiden name, Torrens, he assumed in 1863), was born near Dublin, 13th October 1813. He went to the bar, and in 1835 became an active member of the special commission on Irish poor-relief, which resulted in the extension of the workhouse system in Ireland in 1838. His work, which involved travelling all over the country, started him on the path of useful social reform, which he followed up by doing much to encourage the establishment of mechanics' institutes and other modes of helping popular education. In the 'forties he joined the Anti-Corn-Law League, and in 1846 published his *Industrial History of Free Nations*. In 1847 he was elected to Parliament for Dundalk, and sat till 1852. In 1857 he was elected as a Liberal for Yarmouth, and from 1865 to 1885 he represented Finsbury. Torrens was a well-known man in political life, and devoted himself mainly to social questions in Parliament. It was an amendment of his to the Education Bill of 1870 which established the London School Board, and his Artisans' Dwellings Bill in 1868 was an important step in the direction of the clearing away of slums by local authorities: in many other ways, too, he acted as a true philanthropist. He published several books, and his *Twenty Years in Parliament* (1893) and *History of Cabinets* (1894) contain useful material. He died in London, 25th April 1894.

Torres Novas, a town of Portugal, district of Santarem, 19 miles N.N.E. of Santarem. It has manufactures of cottons, linens, jute, paper, leather, and spirits. It was founded probably by Greeks, and was successively in the power of the Romans, Goths, and Arabs, from whom it was conquered in 1148 by Affonso Henriquez. Population (1890), 9256; (1900), 10,738.

Torres Vedras, a town of Portugal, district of Lisbon, 36 miles N.N.W. of Lisbon. Here were the noted fortifications known as the "lines of Torres Vedras," constructed by Lord Wellington in 1810. Here in 1846 the troops of General Saldanha defeated those of the Count de Bomfim, and seized the castle and town. The town possesses hot sulphur baths. Population (1890), 6022; (1900), 6891.

Torrevieja, a town of Spain, province of Alicante, on the southern coast, with railway to Albatera Catral, on the Alicante–Murcia line. Population (1887), 7724; (1897), 7833. The district is famous for its salt beds, which constitute a Government monopoly. The industries are chiefly fisheries, and the making of everything connected with navigation. The roadstead affords safe anchorage for vessels of all sizes. There is an active trade in fruit and agricultural products. Great quantities of salt are produced from several lagoons and smaller pans, the Laguna Grande alone yielding more than one hundred thousand tons a year.

Torrington, a town and borough of Litchfield county, Connecticut, U.S.A., in the north-western part of the state, with a large rural population. The borough is on the Naugatuck river, and on a branch of the New York, New Haven, and Hartford Railroad. The river furnishes good water-power, which has been utilized in varied manufactures. The town was incorporated in 1740, the borough in 1887. John Brown, the noted Abolitionist, was born in Torrington, 9th May 1800. Population of the town (1880), 3327; (1890), 6048; (1900), 12,453; of the borough (1890), 4283; (1900), 8360, of whom 2565 were foreign-born.

Torrington, Great, a municipal borough, railway station, and market town, Devonshire, England, in the South Molton parliamentary division of the county, 7 miles south-south-east of Bideford, on the Torridge. It is finely situated on a hill 300 feet high, and the river is here crossed by three bridges. A cattle market was erected in 1893, and a cottage hospital in 1897. The town received incorporation charters from Mary, James I., and James II., but all the borough records were destroyed by fire in 1724. There is a manufacture of silk gloves. Population (1891), 3436; (1901), 3241.

Tortosa, a town of Spain, province of Tarragona, on the Ebro, with a station on the coast railway from Valencia to Tarragona. The surrounding country produces oil, wheat, wine, fruit, and vegetables. No place in Spain for centuries has been so often seriously flooded. Many of the streets have been entirely rebuilt, and on the opposite bank of the Ebro a new suburb has sprung up, with modern buildings, squares, and better-paved streets. The fortifications are still standing, but are obsolete, the citadel being used as barracks and hospital. Population (1887), 25,192; (1897), 23,793.

Torts.—Tort is, in the law of England and the United States, the technical name of a civil wrong, *i.e.*, the breach of a duty imposed by law, by which breach some person becomes entitled to sue for damages. A tort must, on the one hand, be an act which violates a general duty. The rule which it breaks must be one made by the law, not,

as in the case of a mere breach of contract, a rule which the law protects because the parties have made it for themselves. On the other hand, a tort is essentially the source of a private right of action. An offence which is punishable, but for which no one can bring a civil action, is not a tort. It is quite possible for one and the same act to be a tort and a breach of contract, or a tort and a crime; it is even possible in one class of cases for the plaintiff to have the option—for purposes of procedural advantage—of treating a real tort as a fictitious contract; but there is no necessary or general connexion. Again, it is not the case that pecuniary damages are always or necessarily the only remedy for a tort; but the right to bring an action in common law jurisdiction, as distinct from equity, matrimonial, or admiralty jurisdiction, with the consequent right to damages, is invariably present where a tort has been committed.

This technical use of the French word *tort* (which at one time was nearly becoming a synonym of *wrong* in literary English) is not very ancient, and anything like systematic treatment of the subject as a whole is very modern. Since about the middle of the 19th century there has been a current assumption that all civil causes of action must be founded on either contract or tort; but there is no historical foundation for this doctrine, though modified forms of the action of trespass did in practice largely supplant other more archaic forms of action by reason of their greater convenience.

The general scope of the law of torts has never been formulated by authority, the law having in fact been developed by a series of disconnected experiments with the various forms of action which seemed from time to time to promise the widest and most useful remedies. A short historical summary will be found in the article under this heading in the ninth edition of this work. But there is no doubt that the duties enforced by the English law of torts are broadly those which the Roman institutional writers summed up in the precept *Alterum non laedere*. Every member of a civilized commonwealth is entitled to require of others a certain amount of respect for his person, reputation, and property, and a certain amount of care and caution when they go about undertakings attended with risk to their neighbours. The precise amount of responsibility can be determined only by full consideration in each class of cases. It is important to observe, however, that a law of responsibility confined to a man's own personal acts and defaults would be of next to no practical use under the conditions of modern society. What makes the law of torts really effective, especially with regard to redress for harm suffered by negligence, is the universal rule of law that every one is answerable for the acts and defaults of his servants (that is, all persons acting under his direction and taking their orders from him or some one representing him) in the course of their employment. The person actually in fault is not the less answerable, but the remedy against him is very commonly not worth pursuing. But for this rule corporations could not be liable for any negligence of their servants, however disastrous to innocent persons, except so far as it might happen to constitute a breach of some express undertaking. We have spoken of the rule as universal, but, in the case of one servant of the same employer being injured by the default of another, an unfortunate aberration of the courts, which started about two generations ago from small beginnings, was pushed to extreme results, and led to great hardship. A partial remedy was applied in 1880 by the Employers' Liability Act; and in 1897 a much bolder step was taken by the Workmen's Compensation Act. But, as the common law and the two Acts (which proceed on entirely different principles) cover different fields, with a good deal of overlapping, and the Acts are full of complicated provisoes and exceptions, and contain very special provisions as to procedure, the improvement in substantial justice has been bought, so far, at the price of great confusion in the form of the law, and considerable difficulty in ascertaining what it is in any but the most obvious cases. The Workmen's Compensation Act includes cases of pure accident, where there is no fault at all, or none that can be proved, and therefore goes beyond the reasons of liability with which the law of torts has to do. In fact, it establishes a kind of compulsory insurance, which can be justified only on wider grounds of policy.

Employers' liability.

There are kinds of cases, on the other hand, in which the law, without aid from legislation, has imposed on occupiers and other persons in analogous positions a duty stricter than that of being answerable for themselves and their servants. Duties of this kind have been called "duties of insuring safety." Generally they extend to having the building, structure, or works in such order, having regard to the nature of the case, as not to create any danger to persons lawfully frequenting, using, or passing by them, which the exercise of reasonable care and skill could have avoided; but in some cases of "extra-hazardous" risk, even proof of all possible diligence—according to English authority, which is not unanimously accepted in America—will not suffice. There has lately been a notable tendency to extend these principles to the duties incurred towards the public by local authorities who undertake public works. Positive duties created by statute are on a similar footing, so far as the breach of them is capable of giving rise to any private right of action.

The classification of actionable wrongs is perplexing, not because it is difficult to find a scheme of division, but because it is easier to find many than to adhere to any one of them. We may start either from the character of the defendant's act or omission, with regard to his knowledge, intention, and otherwise; or from the character of the harm suffered by the plaintiff. Whichever of these we take as the primary line of distinction, the results can seldom be worked out without calling in the other. Taking first the defendant's position, the widest governing principle is that, apart from various recognized grounds of immunity, a man is answerable for the "natural and probable" consequences of his acts; *i.e.*, such consequences as a reasonable man in his place should have foreseen as probable. Still more is he answerable for what he did actually foresee and intend. Knowledge of particular facts may be necessary to make particular kinds of conduct wrongful. Such is the rule in the case of fraud and other allied wrongs, including what is rather unhappily called "slander of title," and what is coming to be known as "unfair competition" in the matter of trade names and descriptions, short of actual piracy of trade-marks. But where an absolute right to security for one's person, reputation, or goods is interfered with, neither knowledge nor specific intention need be proved. In these cases we trespass altogether at our peril. It is in general the habit of the law to judge acts by their apparent tendency, and not by the actor's feelings or desires. I cannot excuse myself by good motives for infringing another man's rights, whatever other grounds of excuse may be available; and it is now settled conversely, though after much doubt, and not without considerable dissent, that an act not otherwise unlawful is not, as a rule, made unlawful by being done from an evil motive. This rule was known some time ago to apply to the exercise of rights of property, and such speculative doubt as remained has

lately been removed. Since the decision of the House of Lords in the leading case of *Allen* v. *Flood* (1898, A. C. 1), we know that it applies to the exercise of all common rights. The exceptions are very few, and must be explained by exceptional reasons. Indeed, only two are known to the present writer—malicious prosecution, and the misuse of a "privileged occasion" which would justify the communication of defamatory matter if made in good faith. In each case the wrong lies in the deliberate perversion of a right or privilege allowed for the public good, though the precise extent of the analogy is not certain at present.[1] It must be remembered, however, that the presence or absence of personal ill-will, and the behaviour of the parties generally, may have an important effect, when liability is proved or admitted, in mitigating or aggravating the amount of damages awarded by juries and allowed by the court to be reasonable. It may likewise be noted, by way of caution, that some problems of criminal law, with which we are not here concerned, require more subtle consideration. However, it is hardly ever safe to assume that the bounds of civil and criminal liability will be found coextensive. Perhaps we may go so far as to say that a man is neither civilly nor criminally liable for a mere omission (not being disobedience to a lawful command which he was bound to obey), unless he has in some way assumed a special duty of doing the act omitted.

We have already had to mention the existence of grounds of immunity for acts that would otherwise be wrongful. Such grounds there must be if the law is to be enforced and justice administered at all, and if the business of life is to be carried on with any freedom. Roughly speaking, we find in these cases one of the following conditions. Either the defendant was executing a lawful authority; or he was justified by extraordinary necessity; or he was doing something permitted by legislation for reasons of superior utility, though it may produce damage to others, and either with or without special provisions for compensating damage; or he was exercising a common right in matters open to free use and competition; or the plaintiff had, by consent or otherwise, disabled himself from having any grievance. Pure accident will hardly seem to any one who is not a lawyer to be a special ground of exemption, the question being rather how it could ever be supposed to be a ground of liability. But it was supposed so by many lawyers down to recent times; the reason lying in a history of archaic ideas too long to be traced here. Exercise of common rights is the category where most difficulty arises. Here, in fact, the point at which a man's freedom is limited by his neighbour's has to be fixed by a sense of policy not capable of formal demonstration. As Chief Justice Holmes of Massachusetts has said, we allow unlimited trade competition (so long as it is without fraud) though we know that many traders must suffer, and some may be ruined by it, because we hold that free competition is worth more to society than it costs. A state with different economic foundations might have a different law on this as on many other points. This freedom extends not only to the exercise of one's calling, but to choosing with whom and under what conditions one will exercise it. Also the law will not inquire with what motives a common right is exercised; and this applies to the ordinary rights of an owner in the use of his property as well as to the right of every man to carry on his business.[2] Owners and occupiers of immovable property are bound, indeed, to respect one another's convenience within certain limits. The maxim or precept *Sic utere tuo ut alienum non laedas* does not mean that I must not use my land in any way which can possibly diminish the profit or amenity of my neighbour's. That would be false. It is a warning that both his rights and mine extend beyond being free from actual unlawful entry, and that if either of us takes too literally the more popular but even less accurate maxim, "Every man may do as he will with his own," he will find that there is such a head of the law as Nuisance.

From the point of view of the plaintiff, as regards the kind of damage suffered by him, actionable wrongs may be divided into four groups. We have some of a strictly personal kind; some which affect ownership and rights analogous to ownership; some which extend to the safety, convenience, and profit of life generally—in short, to a man's estate in the widest sense; and some which may, according to circumstances, result in damage to person, property, or estate, any or all of them. Personal wrongs touching a man's body or honour are assault, false imprisonment, seduction or "enticing away" of members of his family. Wrongs to property are trespass to land or goods, "conversion" of goods (*i.e.*, wrongful assumption of dominion over them), disturbance of easements and other individual rights in property not amounting to exclusive possession. Trespass is essentially a wrong to possession; but with the aid of actions "on the case" the ground is practically covered. Then there are infringements of incorporeal rights which, though not the subject of trespass proper, are exclusive rights of enjoyment and have many incidents of ownership. Actions, in some cases expressly given by statute, lie for the piracy of copyright, patents, and trade marks. Wrongs to a man's estate in the larger sense above noted are defamation (not a strictly personal wrong, because according to English common law the temporal damage, not the insult, is, rightly or wrongly, made the ground of action); deceit, so-called "slander of title" and fraudulent trade competition, which are really varieties of deceit; malicious prosecution; and nuisance, which, though most important as affecting the enjoyment of property, is not considered in that relation only. Finally, we have the results of negligence and omission to perform special duties regarding the safety of one's neighbours or customers, or the public, which may affect person, property, or estate generally.

The law of wrongs is made to do a great deal of work which, in a system less dependent on historical conditions, we should expect to find done by the law of property. The law of negligence, with the refined discussions of the

[1] It was until lately supposed that an action by a party to a contract against a third person for procuring the other party to break his contract was within the same class, *i.e.*, that malice must be proved. But since *Allen* v. *Flood*, and the later decision of the House of Lords in *Quinn* v. *Leathem* (1901, A. C. 495), this view seems untenable. The ground of action is the intentional violation of an existing legal right.

[2] The rule that a man's motives for exercising his common rights are not examinable involves the consequence that advising or procuring another, who is a free agent, to do an act of this kind can, *a fortiori*, not be an actionable wrong at the suit of a third person who is damnified by the act, and that whatever the adviser's motives may be. This appears to be included in the decision of the House of Lords in *Allen* v. *Flood*. So far as we can learn, that decision, though not binding in any American court, is in fact likely to be approved and followed in most American jurisdictions. It is otherwise where a system of coercion is exercised on a man's workmen or customers in order to injure him in his business. The extension of immunity to such conduct would destroy the value of the common right which the law protects: *Quinn* v. *Leathem*. The coercion need not be physical, and the wrong as a whole may be made up of acts none of which taken alone would be a cause of action. In this point there is nothing novel, for it is so in almost every case of nuisance. Conspiracy is naturally a frequent element in such cases, but it does not appear to be necessary; if it were, millionaires and corporations might exceed the bounds of lawful competition with impunity whenever they were strong enough. The reasons given in *Quinn* v. *Leathem* are many and various, but the decision is quite consistent with *Allen* v. *Flood*.

test and measure of liability which it has introduced, is wholly modern; and the same may be said of the present working law of nuisance, though the term is of respectable antiquity. Most recent of all is the rubric of "unfair competition," which is fast acquiring great importance.

It will be observed that the English law of torts answers approximately in its purpose and contents to the Roman law of obligations *ex delicto* and *quasi ex delicto*. When we have allowed for the peculiar treatment of rights of property in the common law, and remembered that, according to one plausible theory, the Roman law of Possession itself is closely connected in its origin with the law of delicts, we shall find the correspondence at least as close as might be expected *à priori*. Nor is the correspondence to be explained by borrowing, for this branch of the common law seems to owe less to the classical Roman or mediæval Canon law than any other. Some few misunderstood Roman maxims have done considerable harm in detail, but the principles have been worked out in all but complete independence.

A list of modern books and monographs will be found at the end of the article on "Torts" by the present writer in the *Encyclopædia of the Laws of England*, vol. xii. p. 195. (Pollock's *Law of Torts* has reached a sixth edition, 1901.) He is not aware that anything new and important has been published on the subject since the date, September 1898, down to which that volume was revised. (F. Po)

Toru. See Uganda.

Totana, a town of Spain, province of Murcia, to the S.W. of Murcia, on the river Sangonera, with a station on the line from Murcia to Lorca. The surrounding country is mountainous to the north and level to the south, generally fertile, and producing wheat, almonds, olives, oranges, and other fruit. The town consists of two parts, styled Barrios de Sevilla and Triana, and has a fine square, large town hall, parish church with three naves (Santiago Apostle). Water is brought in for the fountains by an aqueduct 7 miles long from the Sierra de Espuña to a large reservoir in Jaspe, and a canal has been made from the Sangonera to the beach at Mazarron. Population (1887), 11,021; (1897), 11,634.

Totnes, a municipal borough, railway station, and market town, Devonshire, England, in the Totnes parliamentary division of the county, on the river Dart, 23 miles south by west of Exeter. It is connected with the suburb of Bridgetown by a stone bridge. From 1295 to 1867 (when it was disfranchised) the borough sent two members to Parliament. The church of St Mary's (Early Perpendicular) is a fine one, with a peal of eight bells. It was reopened after restoration in 1889. A cottage hospital was built in 1901. The town was originally walled and entered by four gates; only the east and north remain. Bridgetown is now included in the municipal borough. Population (1891), 4113; (1901), 4034.

Totonicapan, chief town of a department of the same name, Guatemala, Central America. It is beautifully situated amidst luxuriant gardens on the same high plateau as Quezaltenango, from which it is some 12 miles distant to the north-east. It is inhabited mainly by Quiche Indians, employed chiefly in the making of cloth, furniture, pottery ware, and wooden musical instruments. There are hot mineral springs in the neighbourhood. Population, 25,000.

Tottenham, a suburb of London, in the Tottenham parliamentary division of Middlesex, 6 miles north of Liverpool Street by rail. A Roman Catholic church has been built, and Bruce Castle, an Elizabethan mansion, became public property in 1892, with its grounds of 20 acres. The Alexandra Palace is partly in this parish and partly in that of Muswell Hill. Population of the urban district (subdivided in 1888 into two districts, Tottenham and Wood Green) (1891), 71,343; (1901), 102,519.

Tottenville, formerly a village in Richmond county, New York, U.S.A., and since 1st January 1898 a part of Richmond borough, one of the five boroughs constituting New York City. It is near the south end of Staten Island, at the terminus of the Staten Island Railway. The population is not separately returned by the census.

Touch. See Physiology: *Special Senses*.

Toul, chief town of arrondissement, department of Meurthe-et-Moselle, France, 14 miles west of Nancy, on the railway from Paris to Strasbourg. On the north side of the Marne and Rhine canal is the artillery park. In the garden behind the Hotel de Ville is a statue of "France recueillie" by Maindron (1874). At Bellevue, ½ mile north-west of the town, are large pottery works. The manufacture of embroidery is a local industry. Toul is now the centre of a vast entrenched camp. The hills surrounding the town are crowned with forts, constantly being strengthened, of which the highest is that of St Michel (1400 feet), whilst a series of forts, extending in echelon along the ridge bordering the Meuse, connects the fortifications with those of Verdun. Port traffic on the Canal de l'Est and Marne and Rhine amounted in 1900 to 251,561 tons. Population (1891), 8233; (1901), 9026.

Toulon, seaport and first-class fortress and torpedo station of France, department of Var, capital of the arrondissement of Toulon, on the Mediterranean, 42 miles east-south-east of Marseilles. It is the most important port in connexion with the French national military marine. It is frequently visited by foreign naval squadrons, and made the scene of friendly demonstrations not without political significance. The federation monument in commemoration of the centenary of the French Revolution was erected in 1890 in the Place de la Liberté, the finest in the new town. In 1883–87 a handsome Renaissance building was erected to accommodate the picture gallery and the town library. The principal industries, apart from the arsenal, are shipbuilding, fishing, lace-making, and wine-growing. Toulon possesses an observatory and a botanical garden. The Missiessy wet dock was added in 1889 to the naval arsenal. In 1899, 379 vessels of 162,707 tons entered, and 376 of 160,708 tons cleared. Population (1886), 53,941; (1901), 101,172. (See Dockyards: *French*.)

Toulouse, chief town of the department of Haute-Garonne, on the Garonne, 443 miles from Paris by rail. In respect of population it is the sixth town of France, and is the actual metropolis of this southern district, if judged by its historic and commercial importance. The Canal du Midi (between Bordeaux and Cette) has ceased to belong to the Southern Railways Company, and the shipping trade should receive a great impetus by reason of the consequent reduction in the tariffs. The monuments, in which the town is so rich, are restored and kept in repair. A colonnade and front were added to Notre Dame de la Daurade between 1890 and 1895, and at the back of the Capitole a façade has been built in place of the old, incongruous buildings, of which only the keep (now the depository of the archives) has been retained. The magnificent Hôtel d'Assézat has been bequeathed to the learned societies of Toulouse, which took possession of it in 1896; and the learned societies of all France, which for years had convened their annual sittings at Paris, held their congress in this building in 1899. The surplus

treasures of the rich Museum of Antiquities have been bestowed on the Musée St Raymond, in which are various archæological, numismatic, and ethnological collections. The faculties of science, literature, law, and medicine, combined with pharmacy, were constituted a university in the year 1896. Population (1886), 123,040; (1901), 147,696.

Tourcoing, a town in the arrondissement of Lille, department of Nord, France, 2 miles north-west of Roubaix and 7½ miles north-east by north of Lille. A branch canal (1893) connects with the Roubaix canal. The town has extended in all directions, and many churches and public buildings have been erected, including an important school of industries and the Hôtel de Ville, an elegant structure in the Renaissance style, containing a museum of painting and sculpture. An abundant water-supply has been introduced. The industrial and commercial expansion has been very rapid, and Tourcoing now ranks as one of the foremost manufacturing centres of France. In 1897 there were 12 combing establishments employing 4800 persons; 58 spinning and twisting factories, with 580,000 spindles, employing 6460 persons, and producing 40,000,000 lb of yarn; 15 cotton spinning and twisting factories, with 540,000 spindles worked by 4200 persons, and producing 27,000,000 lb of yarn. In the weaving departments 4000 machine and 1000 hand looms turn out woollen and mixed woollen and cotton fabrics to the value of £1,400,000 every year, while the production of drapery, swan-skins, and jerseys is valued at £960,000 more. The making of velvet pile carpets has also greatly expanded, and the annual value of the output of that and allied industries now exceeds £500,000. Imports amounted in 1900 to £2,992,000, and exports to £5,164,000. The principal imports in 1898 were wool, forming 48 per cent., and flax, yarn, and hemp, together making up 20 per cent. of the total. Of the exports, combed wool, &c., accounted for nearly 70 per cent., while yarn, tissues, rags, and flax together made up nearly 16 per cent. of the total. Population (1891), 47,253; (1901), 78,233.

Tournai, a town of Belgium, in the province of Hainaut, 30 miles north-west of Mons, with a station at the junction of lines from Brussels to Lille (France) and from Mons to Courtrai. The Scheldt divides the town into two portions. Its manufacture of carpets is of ancient origin, but has declined in importance. Other industries include the manufacture of woollen and cotton goods, linen bleaching, and distilling. The public buildings are numerous and interesting. Population (1890), 34,442; (1900), 35,004.

Tours, chief town of the department of Indre-et-Loire, France, 145 miles south-west of Paris, on the railway from Paris to Bordeaux. The basilica erected over the tomb of St Martin was discovered as the result of excavations undertaken in 1860. Statues of Balzac (1889) and General Meusnier (1888) have been added to the public monuments. The printing works now give employment to only 800 persons, but have storage accommodation for 7 millions of books. Steel works, works for the manufacture of machinery and implements, iron foundries, and chemical works have become important industrial features. Population (1891), 54,283; (1901), 58,409.

Towanda, a borough of Pennsylvania, U.S.A., capital of Bradford county, on the North Branch of the Susquehanna river, and on the Lehigh Valley and the Barclay railways, in the north-eastern part of the state, at an altitude of 720 feet. It is in a lumber and farming region, and has planing-mills, furniture factories, and foundries. Population (1890), 4169; (1900), 4663, of whom 322 were foreign-born.

Townsville, a town, Queensland, Australia, on Cleveland Bay, about 870 miles north-west of Brisbane, in the county of Elphinstone. It has several handsome public buildings, including the Supreme Court and new custom-house. An excellent water-supply has been established. The tidal harbour is enclosed by stone breakwaters. Large vessels enter, and load frozen meat direct from the refrigerator cars. The port is an outlet for a wide area of pastoral country and for several goldfields, and has regular communication with all ports north and south by lines of steamers. The exports in 1899 were valued at over £3,000,000. The immigration barracks on Ross Island have accommodation for 500 persons. The railway station is the terminus of the Northern line, which extends 236 miles to Hughenden. Population (1891), 8564; (1901), 12,717.

Trade, Balance of. See BALANCE OF TRADE.

Trade Marks.—This subject may conveniently be considered under the following heads: I. British Trade Marks before the Registration Acts, 1883–88; II. Trade Marks under the Registration Acts, 1883–88; III. "Passing off" and trade name; IV. Merchandise Marks; V. International and Imperial Arrangements; VI. Foreign and Colonial Trade Mark Laws.

I. *Before the Registration Acts.*—A trade mark may be defined as a symbol, consisting in general of a picture, a label, or a word or words, applied or attached to a trader's goods for the purpose of distinguishing them from the similar goods of other traders, and of identifying them as his goods, or those of his successors in the business in which they are produced or put forward for sale. A trade mark differs both from a patent and from a copyright in its legal character. In the case of a trade mark the property and the right to protection are in the device or symbol which is invented and adopted to designate the goods to be sold, and not in the article which is manufactured and sold. The article is open to the whole world to manufacture and sell, and all that the owner of the trade mark is entitled to prevent is such a use of his mark by other traders as will suggest that goods which are not his actually are so. On the other hand, patent-right and copyright protect the substance of the articles; and any unauthorized manufacture of it in the former case, or reproduction of it in the latter, while the protection lasts, is prohibited. The grounds, however, on which trade marks, patent-right, and copyright obtain legal recognition, though they are to a certain extent dissimilar, have a common element. Patent-right and copyright rest upon the view that the results of the original labour of the inventor and the author ought, as a matter alike of justice and of public policy, to be secured against piracy; while, as regards the proprietor of a trade mark, the question of originality, so long as the mark is sufficiently distinctive really to identify his goods (and, for purposes of registration, to satisfy the Trade Marks Acts) does not arise. But into the law of trade marks as well as into that of patents or copyright the element enters of a man's right to have the profit derivable from his own property guaranteed to him. "No man," said Lord Justice James in the case of the *Singer Manufacturing Co.* v. *Loog* (1880), defining in language that has become classic the foundation on which the law relating to trade marks rests, "is entitled to present his goods as being the goods of another man, and no man is permitted to use any mark, sign, or symbol, device or means, whereby,

without making a direct false representation himself to a purchaser from him, he enables such purchaser to tell a lie or to make a false representation to somebody else who is the ultimate customer." The existing law in the United Kingdom cannot be properly appreciated unless the subject is approached in the first instance from the historical side. English trade mark law practically commences with the first years of the 19th century. The use of trade marks was indeed of far earlier date, for in 1742 we find Lord Hardwicke declaring that "every particular trader had some particular mark or stamp." But in the very case in which Lord Hardwicke made that statement (*Blanchard* v. *Hill*) he refused to protect the "Great Mogul" stamp on cards, being apparently under the influence of the notion that the legal recognition of trade marks would involve the creation of a new species of monopoly; and with regard to a case decided in the reign of James I. (*Southern* v. *How*), in which a clothier had applied the mark of another clothier to his own inferior goods, the reports leave it doubtful whether the action was brought by the owner of the mark, or by a defrauded customer, in which latter event it would be merely an ordinary action for deceit. But although the actual law of trade marks cannot be traced farther back than the beginning of the 19th century, Lord Eldon repeatedly granted injunctions to restrain one trader from fraudulently "passing off" his goods as those of another, and thus laid a foundation on which the present law has been built up. The stages through which its development passed possess considerable interest, and may be described quite briefly. The first reported case—apart from the doubtful one in the time of James I. above referred to—in which the infringement of a trade mark (a label on blacking) was restrained by the Court of Chancery was *Day* v. *Day* in 1816. In 1824 the common law courts, in the case of *Sykes* v. *Sykes*, established the right of the owner of an infringed trade mark to damages. In 1833 it was held by the Court of King's Bench that it was not necessary for the plaintiff in an infringement action to prove that the defendant's goods were inferior to his, or that he had suffered special damage by the infringement. Later this became a rule of equity as well as of law. On another point, however, the practice of the courts of common law and equity diverged for a time. It was decided by Lord Cottenham in 1838, in the leading case of *Millington* v. *Fox*, that an injunction to restrain the infringement of a trade mark could be obtained, even although the defendant had acted without fraudulent intent. On the common law side, on the other hand, fraud was an essential ingredient in the cause of action, and remained so till the fusion of law and equity by the Judicature Acts.

The effect of Lord Cottenham's decision in the case of *Millington* v. *Fox* clearly was to recognize a right of property in trade marks, and the action for infringement became a familiar species of litigation. Under the then existing law, however, the plaintiff in such actions generally found himself in a very disadvantageous and unsatisfactory position. The basis of his action was the reputed association between his trade mark and his goods. This association the defendant—often a person of no means—would deny, and it had to be proved as a fact by witnesses at a cost which there was little hope of his recovering. Moreover, even if the trade mark proprietor secured a judgment in his favour, it carried with it no immunity from the obligation of again establishing his right to the mark against any subsequent infringer who chose to dispute it. Thus—to take an interesting and pertinent illustration given in Kerly on *Trade Marks* (p. 6)—the case of *Rodgers* v. *Nowill* lasted five years and cost the plaintiff £2211, without giving him in the end any security that he might not have to incur equal delay and expense in proving his title to the exclusive use of the trade mark in proceeding against other defendants. To complete this statement of the shortcomings of the law before the Merchandise Marks Act, 1862, it should be noted that the infringement of trade marks—except in cases where the seller of spuriously marked goods cheated the buyer—was not a criminal offence. The remedies needed obviously were the establishment of a system of registration of trade marks, which would simplify the proof of a plaintiff's title, and the creation of a criminal law of false marking. The first step in the accomplishment of the latter object was taken by the Merchandise Marks Act, 1862, while provision was first made for the registration of trade marks by the Trade Marks Registration Act, 1875. That statute made registration in the register of trade marks which it established *primâ facie* evidence of the right of the registered proprietor to the exclusive use of the trade mark in connexion with goods of the class for which it was registered and used, and enacted that it should after the expiration of five years be conclusive proof of such right, provided that the proprietor of the mark remained the owner of the goodwill of the business in which it was used. The Act also provided that a person should not be entitled to institute any proceeding to prevent the infringement of trade mark until it was registered, or (a later statutory modification) until, in the case of a mark in use before the passing of the Act of 1875, registration of the mark as a trade mark had been refused. The Trade Marks Registration Act of 1875 was a considerable success, but no provision was made under it for the registration of words unless they either were old marks, or were registered in combination with one or more of the "essential particulars" prescribed by the Act, such as a distinctive device, heading, mark, label, or ticket. The Trade Marks Act, 1883, remedied this defect, besides altering the law in other important respects; and the law and practice in regard to trade marks are now embodied in that statute, in an amending Act passed in 1888, on the recommendation of a committee presided over by Lord Herschell, and in rules made by the Board of Trade in 1890, 1897, and 1898. Further reference may be made, in regard to the subject of trade marks before the Registration Acts, 1883–88, to an admirable introductory chapter in Kerly on *Trade Marks*, pp. 1–10, and also to the report of the Merchandise Marks Committee, 1862, and the annual reports of the Commissioners and the Comptroller-General of Patents from 1876 to 1884 (2nd Report).

II. *Under the Acts.*—The Register of Trade Marks is kept at the Patent Office, Southampton Buildings, London, and is under the charge of the Comptroller-General of Patents, Designs, and Trade Marks, who is appointed by and acts under the superintendence of the Board of Trade, and has a deputy—the Registrar of Trade Marks. A copy of the entries relating to cotton goods is kept at Manchester; and there is a branch registry at Sheffield containing the marks for metal goods ("Sheffield marks") registered by residents in or within six miles of Hallamshire. The care of this register is vested in the Cutlers' Company, who are substituted for the Comptroller as to registration of "Sheffield marks," but subject to his veto, and subject also to an appeal from him to the courts. The Trade Marks Acts, 1883–88, do not affect the definition of a trade mark at common law, as it has been explained in the preceding portion of this article. A trade mark must still be a distinctive symbol, and it must also be so applied or attached to goods and "go to market" with them that the customer is led by the use of it to connect the goods with the proprietor

Definition.

of the mark. But re-enacting and enlarging the provisions of the Act of 1875, they lay down "essential particulars," of one at least of which a trade mark must consist, in order to entitle its owner to the benefits of registration. These "essential particulars" are as follows:—(*a*) A name of an individual or firm printed, impressed, or woven in some particular and distinctive manner. The name must be in the nominative case. Thus it has been held that the word "Pirie's" in "Pirie's Parchment Bank" did not come within this clause, and ordinary printing type is not printing in a "particular" or "distinctive" manner; (*b*) a written signature, or copy of a written signature of the individual or firm applying for registration—the signature must be the one *bonâ fide* used in business by the individual or firm, and not a fanciful or descriptive name; (*c*) a device, mark, brand, heading, label, or ticket, which is "distinctive," *i.e.*, capable both of identifying the goods as those of the trade mark proprietor, and also of distinguishing them from those of other traders (which are even new to the trade); (*d*) an invented word or invented words; and (*e*) a word or words having no reference to the character or quality of the goods, and not being a geographical name. The registration of "word marks" was first provided for by the Trade Marks Act, 1883. In that statute, however, clause (*d*) read "a fancy word or words not in common use." The expression "fancy word" gave rise to considerable difference of opinion. It was interpreted by the Court of Appeal as equivalent to "obviously meaningless as applied to the article in question," or "obviously non-descriptive." In accordance with this interpretation, the words "gem" for guns, "melrose" for a hair restorer, "electric" for velveteen, and "washerine" for a soap, were all held not to be registrable. On the recommendation, however, in 1887, of a committee appointed by the Board of Trade, and presided over by Lord Herschell, the expression "invented word" was substituted for "fancy word" by the Trade Marks Act, 1888. An invented word need not be wholly meaningless, nor is it disqualified because words may have suggested it. Thus "mazawattee" was held to be an "invented word," although the latter part of it was a Cingalese term meaning "estate," and there were estates in Ceylon having names ending with "wattee," from which tea came; and in a leading case on the construction of the clauses under consideration (*Eastman Co.'s Trade Mark*, 1898, 15 Rep. Pat. Cas. 476), the word "solio" was held to be registrable as a trade mark for photographic printing paper under both clauses, although it was objected that "solio" was equivalent to "sunio." Clauses (*d*) and (*e*), it should be noted, are independent: the former deals with newly-coined words, the latter with the existing words of the English language, or of other languages likely to be known to the public. A word which is really "invented" may be registered, whether it is descriptive or not.

Fancy words.

There may be added to any one or more of the "essential particulars" above enumerated any letters, words, or figures, or a combination of these. But the right to the exclusive use of the added matter must be disclaimed. A man is not required, however, to disclaim his own name, or trade name, or that of his place of business, if the name appears in the mark. In the case of what are called "old marks," viz., those used before the Trade Marks Registration Act, 1875, there may also be added to the mark any device, mark, brand, head, label, or ticket, which, although *primâ facie* distinctive, is really common to the trade.

Even if a trade mark satisfies the statutory conditions as to "essential particulars," it may still under certain circumstances be refused registration by the Comptroller-General. Two or more persons are not allowed, unless the court directs, to be registered as proprietors of the same trade mark with respect to the same description of goods; if it appears that three or more traders are entitled to an old mark for the same description, the mark is treated as common to the trade. Moreover, except by the direction of the court, the Comptroller must not register a mark having such resemblance to one already registered as to be calculated to deceive. The Trade Marks Acts contain elaborate divisions of goods into different classes. But the question whether particular goods are of the same description is not determined solely by reference to the statutory classification. "The true test," says Kerly (*Trade Marks*, p. 181), "would seem to be supplied by the question, Are the two sets of goods so commonly dealt in by the same trader that his customers, knowing his mark in connexion with one set, and seeing it upon the others, would be likely to suppose that it was used upon them also to indicate that they were his goods?" Wine and spirits, beer, and even an aperient drink and baking powder, have been held to be "goods of the same description." The expression "calculated to deceive" has been considered by the courts in very many cases. It is not merely nor chiefly the retailer or dealer that has to be kept in view when the question of the likelihood of deception is under consideration. The courts have regard also, and mainly, to the ultimate purchaser whom the trade mark may reach, and careless or unwary persons are considered as well as those who are careful and intelligent. The judge's eye is the ultimate test as to the degree of resemblance that is calculated to deceive, although expert evidence on the point is admissible.

Registration of a trade mark is equivalent to public user of the mark. It is *primâ facie* evidence, and after five years is conclusive evidence, of the registered proprietor's right to the exclusive use of the mark for the goods for which it is registered, so long as the mark remains on the register (for the court has power, on the application of any person aggrieved by the entry of a mark on the register, to order its removal), provided that the proprietor is the owner of the goodwill of the business in the goods upon which the mark is used. Moreover, it is a condition precedent to an action for the infringement of a trade mark that the plaintiff should be the registered proprietor of the mark at the time when the action comes on for hearing. This last provision does not apply to an action for "passing-off" (see *infra*).

The right to a trade mark is determined if the mark ceases to be distinctive and becomes *publici juris;* if it is separated from the goodwill (a trade mark can only be assigned with the goodwill); if the mark is applied by the trader to spurious goods (as where boxes of cigarettes were so labelled, in conformity with an alleged custom of the trade, as to indicate that they were Russian manufacture, which was not the fact; or when the mark is abandoned (temporary disuse, however, is not abandonment unless the mark has in the meantime become associated with the goods of another trader); or where, as in the "linoleum" case, it has become the name of the goods, and so merely descriptive; or after fourteen years where the trade mark fees have not been paid.

Trade mark rights may be protected and enforced by an action for infringement, which may be brought in the Chancery or King's Bench Division; or, in the case of marks registered upon application at the Manchester office, in the Palatine Chancery Court of Lancashire; or, where not more than £50 damages is claimed, in the county court. As above mentioned, the court has power to rectify the Register of Trade Marks on the application of any person "aggrieved" by any entry in or omission from it; and a mark may be removed even after five years'

registration. The court may, on the application of the registered proprietor of a trade mark, give him leave to alter or add to it (*e.g.*, a firm on becoming a limited company has been allowed to add the word "limited" to its name upon a registered mark), but no alteration will be permitted in regard to any "essential particular." An appeal lies from the refusal, or, where an application is unsuccessfully opposed, from the allowance of registration of a trade mark by the Comptroller-General, to the Board of Trade, which may and frequently does refer the question to the court. The work of the trade mark branch of the Patent Office has not increased at all in proportion to that of the patent branch, and indeed, as regards the number of registrations, shows a tendency to decrease (see article PATENTS). The number of applications for trade marks in 1884 was 7104, and the number of marks registered 4523. In 1899 the corresponding figures were 8918 and 3771.

III. *"Passing-off" and Trade Name.*—A trader has generally numerous other symbols, which he uses as *indicia* of his goods, besides his trade mark, *e.g.*, the name or title under which he himself trades, the name under which his goods are known and sold, badges of property which are termed "trade name," and the distinctive "get-up" of the goods as they appear in the market. These symbols enjoy the protection of the law, under certain conditions, equally with trade marks. No trader is entitled to "pass-off" his goods as those of another, and if he infringes this rule he is liable to an action for an injunction and damages. Even if the "passing-off" is done innocently it will be restrained (*Millington* v. *Fox*, 1838, 3 Mylne and Craig, 338). Although the first purchaser is not deceived, still if the article delivered to him bears words or marks such that it is "calculated to deceive" a purchaser from him, the use of them is illegal. To this general rule there are several exceptions:—(1) No monopoly is allowed in names that are merely descriptive. But words which *primâ facie* are descriptive, such as "camel-hair belting," for belting made of camel-hair (*Reddaway* v. *Banham*, 1896, App. Cas. 199), or "Stone Ales" for ales brewed at Stone (*Montgomery* v. *Thompson*, 1891, App. Cas. 217), may be shown to have acquired by long use "a secondary distinctive meaning," and, in fact, to mean the goods of a particular trader. And where a defendant is not selling the genuine goods indicated by the name, as where the composition of the goods is a secret, even if the name might otherwise be taken as merely that of the goods, he cannot rely on the defence that the name is descriptive (*Birmingham Vinegar Co.* v. *Powell*, 1897, App. Cas. the "Yorkshire Relish Case"). (2) A trader cannot be prevented from trading under his own name, if he is using it honestly, even though from its similarity to the name of another trader it may injure the business of the latter (*Burgess* v. *Burgess*, 1853, 3 De Gex, M. and G. 896; *Turton* v. *Turton*, 1889, 42 Ch. D. 128). But if a trader's own name has, before he entered the trade, become the trade name of some other person's goods, he might probably not be allowed to use it without taking steps to prevent deception. It is provided by the Companies Act, 1862, that no company shall be registered under a name identical with that by which a subsisting company is already registered, or so nearly resembling it as to be calculated to deceive, unless the subsisting company is in process of being wound up and consents to such registration; and provision is also made for a change of the name of any company which, through inadvertence or otherwise, is registered under a name coming within the statutory prohibition. It is to be observed (cf. Buckley, *Companies Acts*, 7th ed. p. 28) that (*a*) the Companies Act applies only to the case of taking the name of a subsisting company already registered, and not to a case where a new company proposes to register in the name of, or in a name closely resembling, the name of an old-established company, which is not registered, or of a firm or individual trader; (*b*) that as soon as the new company is registered the Act ceases to apply; and (*c*) that the Act forbids registration irrespectively of the question whether the business proposed to be carried on by the new company is the same as that of the subsisting company or not. But the provisions of the Companies Act on this subject are merely supplemental to the common law, and, accordingly, an injunction will be granted to restrain a company from carrying on the same trade as that of another company under a name so nearly resembling the name of that company as to be calculated to deceive, whether it has been registered or not, and, in the latter event, to restrain the infringing company from applying for registration of the name. A new company will not be allowed to take the whole name of a subsisting company, even although that name is of a descriptive character (*Manchester Brewery Co. Ltd.* v. *North Cheshire and Manchester Brewery Co. Ltd.*, 1899, App. Cas. 83).

The purchaser of the goodwill of a business has the right to use the trade name under which the business is known, and to restrain others from using it, or using such imitations of it as may mislead the public. But he is not entitled by the use of the trade name to make the vendor liable, under the doctrine of "holding out," for debts of the business incurred after the sale. And if the vendor of the goodwill gave his name to the business, he cannot (in the absence of any restrictive condition in the agreement for sale) be prevented from beginning to trade in his own name again, unless it be shown that in so doing he is attempting to deceive the public into the belief that he is still the owner of the old business. It may be noted that the right to be protected against "passing-off" is restricted to goods of the same description as those upon which the trader uses the "get-up," &c., imitated.

IV. *Merchandise Marks.*—As has already been seen, the first attempt to make the falsification of trade marks a criminal offence was initiated by the Merchandise Marks Act, 1862. But that statute possessed numerous and serious defects. Although it provided that the forgery of a trade mark with intent to defraud, and the false application of a trade mark to goods with the like intent, should be misdemeanours, it left the burden of establishing the fraudulent intent upon the prosecutor. It contained no provision for summary prosecutions. And it did not provide for the seizure of falsely-marked goods on importation from abroad. It was to the existence of this last defect that the enactment of a more satisfactory measure was due. The International Convention for the Protection of Industrial Property, to which Great Britain acceded in 1884, contained a provision that all goods illegally bearing a trade mark or trade name may be seized on importation into those states of the union where the mark or name has a right to legal protection, and that the seizure shall be effected at the request of either the proper public department or of the interested party, pursuant to the internal legislation of each country. The law had to be amended in order to carry out this article in the Convention, and the Merchandise Marks Act, 1887, was passed to carry out this object and generally to make better provision for the protection of merchandise. It was subsequently amended in 1891. The effect of the provisions of these statutes may be briefly stated. Any person is guilty of an offence, punishable on indictment or summary conviction, by fine or imprisonment, who does any of the five following acts, unless he proves as regards the first four

of them that he acted without intent to defraud (there is a special defence to No. v. which is noted below):—(i.) forges any trade mark, or makes, disposes of, or has in his possession for such purpose any die or instrument; (ii.) falsely applies any trade mark or a colourable imitation of any trade mark to goods; (iii.) applies any false trade description to goods: "trade description" is defined as any descriptive statement or other indication as to the measurement, quantity (not *quality*, it should be observed), or weight, place, or mode of production, or the material of the goods, or as to their being subject to an existing patent, privilege, or copyright; conventional or customary descriptions lawfully in use in August 1887 to indicate that the goods are of a particular class or method of manufacture are allowed to be continued; but if they contain the name of a place and are calculated to mislead as to the real place of production, the name of the latter must be added; (iv.) causes any of the above offences to be committed; (v.) sells or exposes for sale, or has in his possession for sale, trade, or manufacture, any goods or things to which any forged trade mark or false trade description is applied, or any trade mark or colourable imitation of a trade mark is falsely applied, unless *the defendant* proves that, having taken all reasonable precautions, he had no ground to suspect the genuineness of the mark, &c., and also that on demand he gave to the prosecutor all the information in his power as to the person from whom he obtained the goods, &c., or proves that he otherwise acted innocently.

Trade description.

There is power to forfeit the things found on a prosecution for any of these offences, although no one is convicted. If the offender is indicted (it is in his option to be tried in this way) the punishment is fine and imprisonment, the latter not to exceed two years. On summary conviction the punishment is not to exceed, for a first offence, four months' imprisonment, with or without hard labour, and a fine of £20; and for any subsequent offence six months' imprisonment and a fine of £50. The importation is forbidden of goods by means of or in relation to which an offence against the Acts has been committed, and also of all goods of foreign manufacture bearing any name or trade name being or purporting to be that of a manufacturer or trader within the country, unless it be accompanied by a definite indication of the country where the goods were made or produced. There are also special provisions with regard to the marking of watch-cases. The Commissioners of Customs have power to make general orders for carrying out the Merchandise Marks Acts, and a number of such regulations have been issued. Under the Sale of Food and Drugs Act, 1899, the importation, except in containers showing their character, of margarine, margarine cheese, adulterated or impoverished butter, or condensed, separated, or skimmed milk, is penalized, and it is provided that the Commissioners of Customs, in accordance with directions given by the Treasury after consultation with the Board of Agriculture, shall take such samples of consignments of imported articles of food as may be necessary for the enforcement of the law.

V. *International and Imperial.*—By the International Convention (see PATENTS) for the Protection of Industrial Property, which was signed at Paris in 1883, the signatory states, a list of which is given below, agreed that the subjects or citizens of each state should, in all the other states, enjoy as regards trade marks and trade names the advantages that their respective laws then granted, or should thereafter grant, to their own subjects or citizens. So far as Great Britain is concerned, the only provision that has been made for carrying out this convention is contained in § 103 of the Trade Marks Act, 1883. The effect of that section is to confer on an applicant for the protection of a trade mark in one of the other contracting states a priority over other applicants for registration in the United Kingdom during the space of four months. The section does not, however, exempt the applicant from the conditions and formalities incumbent on ordinary applicants for registration in Great Britain; nor does the fact that the foreign application has been successful of itself give the applicant a right to have his mark accepted for registration. Under the Convention of Madrid, 1891 (to which, however, Great Britain has not acceded), a trade mark may be registered as the result of a single application in the countries of all the signatory Powers.

The following is a list of the Orders in Council that have been issued applying the provisions of the Trade Marks Act, 1883, § 103, to foreign countries:—

Foreign State.	Date of Order in Council.
Belgium	June 26, 1884.
Brazil	June 26, 1884.
Denmark (including the Faroë Islands)	November 20, 1894.
Dominican Republic	October 21, 1890.
Ecuador	May 16, 1893.
France	June 26, 1884.
Greece	October 15, 1894.
Italy	June 26, 1884.
Japan	October 7, 1899.
Mexico	May 28, 1889.
Netherlands	June 26, 1884.
(East Indian Colonies)	November 17, 1888.
(Curaçoa and Surinam)	May 17, 1890.
Paraguay	September 24, 1886.
Portugal	June 26, 1884.
Rumania	August 5, 1892.
Servia	June 26, 1884.
Spain	June 26, 1884.
Sweden and Norway	July 9, 1885.
Switzerland	June 26, 1884.
Tunis	June 26, 1884.
United States	July 12, 1887.
Uruguay	September 24, 1886.

In the following foreign countries penalties have been imposed under the Foreign Jurisdiction Act on British subjects committing offences against the Trade Marks Acts, 1883–88, and the Orders in Council thereunder—Africa, East Africa, Morocco, Persia, Persian Coast, Zanzibar.

By § 104 of the Trade Marks Act, 1883, the Sovereign is empowered by Order in Council to apply the provisions of § 103, above mentioned, with such variations or additions as may seem fit, to any British possession. The following is a list of the Orders in Council that have been issued:—

British Possessions.	Date of Order in Council.
New Zealand	February 8, 1890.
Queensland	September 17, 1885.
Tasmania	April 30, 1894.
West Australia	May 11, 1895.

It should be added that the protection of the Merchandise Marks Act, 1887, extends to any trade mark which, either with or without registration, is protected by law in any British possession or foreign state to which the provisions of § 103 of the Act of 1883 are, under Order in Council, for the time being applicable.

A foreigner suing in the United Kingdom for infringement of a trade mark or for "passing-off" is in the same position as a subject.

VI. *Foreign and Colonial.*—It is impossible within the limits of this article to attempt a survey of the laws of

foreign countries or of the colonies. Valuable information with regard to the former will be found in the *Transactions* of the International Association for the Protection of Industrial Property, London, vol. i., 1897, pp. 185 ("International Registration"), 245 ("Indications of Origin"), 259 ("Unfair Competition"); vol. ii., 1898, pp. 214 ("Unfair Competition"), 250 ("Industrial Property Department"), 445 ("Descriptive Marks"). The British colonies generally follow the model of the English Trade Marks Acts. The Hong Kong Ordinance, No. 14 of 1898, is a typical instance of this. In the Isle of Man in 1898 a Merchandise Marks Act was passed which proceeds on the lines of the English Act of 1887, and contains an additional section imposing penalties on any person who falsely represents that any goods are made by a person holding a royal warrant, or for the service of the Sovereign or any of the royal family, or any Government department. There is a similar provision in § 105 of the Patents Act, 1883.

AUTHORITIES.—SEBASTIAN. *Trade Marks*, 4th ed. London, 1899 (in this work the American cases are fully dealt with).—KERLY. *Trade Marks*. London, 1894.—CARTMELL'S *Digest*. London, 1876-92.—SEBASTIAN. *Digest*. London (cases down to 1879).—GRAY. *Merchandise Marks Act*. London, 1888.—SAFFORD. *Merchandise Marks*. London, 1893.—The Reports of the Departmental Committee of 1887, and of the Select Committees of the House of Commons appointed in 1887 and 1890 to consider the law with regard to merchandise marks and false marks, and the annual Reports of the Comptroller-General, throw great light on both the history and the practical working of the law. (A. W. R.)

TRADE ORGANIZATION.

THE development of commercial organization which attended the growth of trade and industry during the 19th century has assumed two distinct phases. In the first, we see the creation of associations of persons engaged in trade and industry for the purpose of protecting their interests and of facilitating and fostering commercial relations. In the second, governments elaborate departmental organizations for the supervision of commercial matters, establish offices for the dissemination of commercial information, and utilize their consular services as means of commercial intelligence and influence.

The associations belonging to the first category may be divided into three classes:—

(*a*) Those which are themselves engaged in trade, like ordinary joint-stock companies, or which result from the combination of firms or individuals in the same or connected trades, for the purpose of facilitating or restricting production, limiting competition, regulating prices, &c.—in a word, of working to their common benefit by the union of their property, knowledge, and energies, such as co-operative societies and trusts.

(*b*) Those which, without engaging in trade, aim at providing facilities for the transaction of commercial or financial operations. They chiefly take the form of exchanges, bourses, public sale rooms, &c., such as the Baltic, Lloyd's, the Stock Exchange, the Corn and Coal Exchanges, the Commercial Sale Rooms, and impose upon their subscribers or members rules for the transaction of business which, in certain cases, apply not only to business transacted upon their premises, but also regulate the manner of transacting business generally.

(*c*) Non-trading bodies, in the nature of public institutions, whose objects are to protect the interests of trade; to advise, and if necessary to bring the weight of combined influence to bear upon governments and parliaments in commercial matters; to facilitate the obtaining of commercial information; to secure diplomatic intervention for the upholding of national rights in international trade; and, to a certain extent, to be to trade and traders, under the economic conditions of modern life, what the gilds and crafts and livery companies of former ages were to the merchants and craftsmen of their day.

This article is limited to commercial associations of the last class, and an attempt has been made to show how they arose, the rules which govern them, their sources of income, and the nature and extent of the services which they render to commerce. The systems in force in the United Kingdom and in the British colonies and India, in the United States, in France, Germany, Belgium, Austria-Hungary, Spain, Portugal, Russia, and Japan are the subjects of separate sections, in which will also be found a summary of the steps taken by governments to deal with the requirements of trade by the establishment of Ministries of Commerce, Official Commercial Information Bureaus, Commercial Museums, Consultative Committees, &c. In view of the interest attaching to consular action in trade matters, special attention has been paid to the instructions given to consuls on the subject.

When, at the close of the 18th century and early in the 19th, the power of the old trade gilds and corporations of merchants had been broken by the almost universal proclamation of the liberty of trade and industry, and by the abolition of compulsory apprenticeship, both governments and commercial men soon realized that the ancient societies would not follow the commercial evolution, and that new organizations must be created to meet new requirements. Two systems were evolved, which, from their prototypes, are known as the British and the French systems. In the former, trade organizations were left to develop themselves in their own way, and in whatever directions they might think fit, without any official interference. In the latter, on the contrary, the Government constituted itself the creator of trade organizations, which it incorporated into the administrative system of the country, and to which it gave an official status as an integral part of the machinery of the state. The former have grown chiefly into associations for the promotion and defence of commercial interests, whilst the latter have mainly become sources of commercial information and means of action at the disposal of the Government. While organizations on the British system are, as regards the Government, purely advisory bodies whose opinion might or might not be asked in connexion with commercial matters, and whose duties are limited to the services which they are in a position to render to their members and to commerce generally, organizations on the French system not only must be consulted, in certain specified cases, by the Government, especially in connexion with the drafting of commercial legislation and of regulations affecting trade, but they have also administrative duties to perform, such as the control of public commercial institutions, of testing, standardizing, and conditioning establishments, port and dock works, &c. The former associations are self-supporting, their chief source of income being the annual subscriptions received from members. The latter are provided for out of the rates, and sometimes by government or municipal subsidies. The British system obtains in the United Kingdom and the British colonies, in the United States, and in Belgium, while the French has been adopted in most Continental countries, and in Japan.

British and French systems.

Both systems have advantages, but both have also

great drawbacks. The chief advantages of self-supporting associations, unfettered by official trammels, are that they are free to act as they deem best in the interests of the commercial community, and, if necessary, to bring pressure upon the Government and upon Parliament; that the expression of their views is not coloured by the natural inclination to support the acts of an administration of which they form part; that they can freely join hands with other associations in the advocacy of a common cause; and that they are at liberty, in all cases and at all times, to place their views before the Government. On the other hand, the fact that they have to depend almost exclusively upon the subscriptions of their members often cripples them in their work, as in many places the membership is not sufficient to allow them to develop as they should, and in consequence they are unable to render the services which are expected from them; their library is incomplete, their offices and staff are not in keeping with their character. Moreover, self-supporting associations have a strong tendency to overlook that they are public bodies, with consequent public duties: they naturally want to limit their services to their subscribers, and this gives rise to the taunt of the outsider that they represent nobody but themselves, and that they have no claim to be regarded as public institutions. Great difficulty is experienced in making them truly representative, and their efficiency is not unfrequently impaired by local jealousies. The fact that a particular firm or individual has become a member is often enough to prevent others from joining, and to make them look upon the institution as a mere organization of busybodies.

The Continental system avoids the latter drawbacks. Trade organizations, as a rule, merely consist of a Board the members of which, limited in number, are periodically elected by the general body of commercial tax-payers. Serious guarantees are thus afforded for securing representative organizations. These Boards have an official status, their members take rank after the magistrates in public functions, membership of them confers a standing, and is considered as a public recognition of commercial position and credit. Election to them is in consequence highly coveted. Expenses being borne by the rates, there is no difficulty in providing proper offices, staffs, and libraries, and in maintaining the dignity and in carrying on the work of these associations in a manner suited to their position and to their objects. But, on the other hand, Government control does not go without grave disadvantages. Organizations on the Continental system are, as a rule, so much under the hand of the State that they cannot always be trusted to express fully the views of their constituents, and even if they do express these views, they are powerless to take action to secure their enforcement. Their duties are carefully defined by law, and they have practically no initiative in commercial matters. As they lack the incentive given to associations under the British system by the necessity of continually increasing the number of their subscribers, they are apt to run in a groove, to limit themselves to what they are strictly bound to do, to ignore questions which are difficult or dangerous to deal with, and to confine themselves to matters of purely local interest.

I. Great Britain and Colonies.

A. *Commercial Associations.*

In the United Kingdom, commercial associations arose with the growth of trade, without any assistance from the State and free from all Government restriction or control. The first in point of date were the "Commercial Societies" which were formed, chiefly during the last quarter of the 18th century, in Birmingham, Exeter, Halifax, Leeds, Liverpool, and Manchester, and which exercised a not unimportant influence upon commercial developments at the close of the 18th and in the early years of the 19th centuries. The modern associations which superseded these societies divided themselves into four classes, viz. :—

(*a*) Chambers of Commerce and Associations which aim at becoming representative of general commercial interests;

(*b*) Associations or Institutes which represent particular trades or branches of trades;

(*c*) Trade Protection Societies, which look after the interests of retail as well as wholesale traders, and undertake to supply them with information as to the standing and credit of firms, expose swindlers, collect debts, &c.; and

(*d*) Non-representative associations rendering general commercial services.

All the representative associations are on the same plan, being composed of members who pay a yearly subscription, and as a rule elect a governing body entrusted with the management of the affairs of the society. In some cases the governing body is not elected, but co-opts members to fill vacancies, whilst in others it is partly elected and partly co-opted. This body decides upon applications for membership of the association, which is only granted after inquiries, and when applicants have been duly proposed and seconded, and notice of their applications given.

a) Chambers of Commerce and General Associations.—Most of the Chambers of Commerce in the United Kingdom were formed during the latter half of the 19th century, although a few were in existence much earlier. The oldest British Chamber is the Jersey Chamber, which dates from 1768. The Glasgow Chamber was founded in 1783. Dublin followed in 1785, Edinburgh in 1786, Manchester in 1794, Belfast in 1796, Birmingham in 1813, Newcastle-upon-Tyne in 1818, Liverpool in 1851, Sheffield in 1857, &c. The London Chamber was the last of the Chambers of importance to be established: it dates only from 1881. There are in the United Kingdom 113 Chambers of Commerce, of which ten are in Scotland and ten in Ireland. Some of the older chambers, notably the Glasgow Chamber, have been granted the status of a "body corporate and politic" by Royal Charters, which empowered them to acquire, hold, and dispose of property, and to sue and be sued in a corporate capacity, gave them a corporate seal, embodied the regulations adopted for the internal management of the Chamber, and ordained "that they and their successors in all time coming shall have perpetual succession for the purpose of better and more efficiently administering, directing, ordaining, and constituting in all matters and things" pertaining to the said Chambers and their funds. The obtainment of corporate capacity was rendered easier by the Companies Acts which have been enacted since 1862, and the practice of granting charters to Chambers of Commerce and similar associations was abandoned. Being non-trading bodies, and no part of their income being at any time payable, either directly or indirectly, to the members by way of dividend, bonus, or otherwise, Chambers of Commerce could obtain the Board of Trade licence for incorporation as companies limited by guarantee without the addition of the word "limited." Some twenty chambers, including those in London, Liverpool, Sheffield, Aberdeen, &c., availed themselves of this facility, and are known as Incorporated Chambers of Commerce. Their objects and regulations are embodied in the Memorandum and Articles of Association, and alterations can be made therein in accordance with the provisions of company law. In Chartered Chambers, the rules, which are recited in the charter, cannot be amended except by a supplementary charter, which is a cumbrous and expensive proceeding. The vast majority of Chambers of Commerce, however, did not take the trouble to seek incorporation, and in law are governed by the rules regulating ordinary partnerships, under which the members are personally liable for the debts of the Association.

The London Chamber.

The London Chamber of Commerce, which boasts over 4000 members, is one of the most representative associations of its kind, and the organization adopted has been very effective in securing this. The Chamber has been divided into trade sections, of which there are at present forty-four, and members specify the sections to which they desire to belong. Each section has a separate organization, and is presided over by a chairman elected by itself, who may be helped by an elected committee, if found advisable. The general council of the Chamber confirms the election of chairmen of sections, and no action can be taken by the Chamber on the recommendation of a section unless the council has authorized such action. The result

is that, whilst general interests are safeguarded, particular trade interests are given opportunities of pressing themselves upon the attention of the general body. Questions are also sifted without needless loss of time, as they are in the first place submitted to those who are especially interested in them and especially competent to deal with them, and it is only upon their recommendation that the council is requested to take action. The Chamber has also placed itself in connexion with a number of mercantile associations which, whilst preserving their separate organizations and their independence of action, have found it advantageous to work in conjunction with it, either for general or for particular purposes, and to have a voice in its council. They are twenty-nine in number, the most important of which are the Institute of Bankers, the Institute of Chartered Accountants, the Society of Accountants and Auditors, the General Ship Owners' Society, the General Produce Brokers' Association, the Federation of Grocers' Associations of the United Kingdom, the West India Committee, the Corn Trade Association, the United Planters' Association of Southern India, &c. The general council is composed of 115 members, as follows: four *ex officio*, viz., the Lord Mayor, the Governor of the Bank of England, and the two members of Parliament for the City; two nominated, one by the committee of Lloyd's and the other by the Board of Elder Brethren at Trinity House; twenty-nine elected by the Mercantile Associations working in conjunction with the Chamber; the forty-four chairmen of trade sections; and thirty-six representing the general body of members of the Chamber. The latter are the successors of the original council which took charge of the Chamber at its foundation: they are not elected, but their number is kept up by co-optation as vacancies occur. Various attempts have been made by members of the Chamber to introduce the principle of election to the council, but so far unsuccessfully. An executive committee of the council transacts the general business of the Chamber. Individual members pay an entrance fee of £2, 2s. and an annual subscription of £1, 1s., and may compound for life membership by a single payment of £17, 17s.; firms or companies pay an entrance fee of £2, 2s. and an annual subscription of £2, 2s., and cannot compound. The yearly income of the Chamber is about £7000, and a reserve fund of £2000 has been invested.

Particular reference should also be made to the Liverpool Chamber, which, as regards division into trade sections and co-operation with independent associations, works on similar lines to those of the London Chamber. The African trade section of the Liverpool Chamber has been prominent in connexion with African questions, and since its foundation in 1884 has been the leading voice in all matters relating to West Africa; and its action with reference to health and sanitation questions on the West Coast, and to the establishment of the School of Tropical Medicine, has been effective and beneficent. It also was chiefly instrumental in bringing about the reform of the management of the Niger territory by the Chartered Company, and has been the chief recommendatory power in the making of roads and railways and in the provision of shipping facilities in those regions.

The Liverpool Chamber.

The Manchester Chamber of Commerce is known as the champion of free trade, as the principal exponent of the doctrines of the Manchester school, and as the opponent not only of all attempts to introduce protective customs duties, but of any preferential arrangement in favour of the Colonies which would differentiate between the treatment of colonial goods and that of foreign goods. The Chamber may be said to have inherited its policy from the Anti-Corn Laws Agitation, and from the memorable *rôle* which it played from 1838 onwards in the free-trade campaign. Its action in connexion with factory legislation has also been important. It is more of an economic body than any other Chamber of Commerce in the United Kingdom.

The Manchester Chamber.

Other Chambers of Commerce follow more or less closely the organization explained in connexion with the London Chamber, with the exception that, as a rule, their governing body is elected. Subscriptions are on about the same scale everywhere, viz., ranging from £1, 1s. to £2, 2s. per annum. The Glasgow Chamber has a £5, 5s. subscription.

The Association of Chambers of Commerce of the United Kingdom, which was formed in 1860, contributed much to give Chambers of Commerce as a whole a national importance and a standing which enabled them in course of time to become representative of the general commercial interests of the country, as distinguished from local interests. This Association, like the Chambers themselves, was of course purely voluntary, and at the time of its foundation only sixteen Chambers decided to join it. It was some time before the oldest and most important Chambers became members, as they were rather afraid of having their liberty of action tampered with, and of being compelled by the votes of other Chambers to countenance decisions of which they did not approve. But these fears proved to be groundless, and the only Chamber of importance which is still keeping aloof is the Glasgow Chamber. The Manchester Chamber joined in 1900. In 1902, 96 out of the 113 Chambers in the United Kingdom were members. The management is in the hands of a council composed of a president, two vice-presidents, a treasurer, two honorary secretaries, and twenty-five representatives of constituent Chambers, who are elected by ballot every year at the general meeting of the association. In the proceedings of the Association, Chambers with less than 100 members have one vote; those having from 100 to 250 members, two votes; from 250 to 600, three votes; over 600 and not exceeding 1000, four votes; over 1000, one additional vote per additional 500; but no Chamber can have more than six votes. The Association is kept up by an annual subscription from the constituent Chambers, which is based upon the number of members of each Chamber, and ranges from £8 for Chambers having less than 100 members to £32 for Chambers having up to 1000, and £8 additional for each further 500 members. Its income from subscriptions amounts to about £1000 per annum, and its budget from all sources to about £1500. It was incorporated under the Companies Acts in 1875, and its chief objects are stated to be:—To afford Chambers of Commerce opportunities of discussing matters of common interest and of deciding upon joint action in relation thereto; to act as intermediary between the constituent Chambers and the Government in matters in regard to which the intervention of the Association is requested; to petition Parliament, and to promote or oppose Bills affecting commercial, manufacturing, and shipping interests, &c. It has been instrumental in passing many useful Acts of Parliament, and in otherwise influencing legislation upon commercial topics. The general meetings, which are held annually in March, in London, and at which delegates are present from all parts of the country, have come to be considered as a kind of parliament of trade, and representatives of the Board of Trade, the General Post Office, and the Foreign and Colonial Offices are generally in attendance. Special meetings take place in September, and are held in provincial towns on the invitation of the local Chamber. During the Exhibition of 1900 the special meeting for that year took place in Paris, on the invitation of the British Chamber of Commerce in that city, which is a member of the Association. The reception which was accorded to the visitors by the French Government and by the Chambers of Commerce of Paris and Calais, as well as the fact of the visit to France of such a representative body of British commercial men at a time when the relations between the two countries were not thought to be at their best, had a most beneficent effect both in France and in England, and opened up a vista of possibilities concerning the influence of Chambers of Commerce in international relations which had not hitherto received sufficient attention.

Association of Chambers of Commerce.

The Association has limited its work to the United Kingdom, and has not taken advantage of the commercial development of the Colonies to afford colonial interests an opportunity of voicing their needs in the metropolis. To supply this need the London Chamber of Commerce organized Congresses of Chambers of Commerce of the Empire, of which up to 1902 four had taken place, viz., in 1886, 1892, 1896, and 1900. These Congresses, to which all Chambers of Commerce in the United Kingdom and in the Colonies and India were invited to send delegates resident in their district, enabled British commercial men, as well as the representatives of the Government who were invited to attend, to become acquainted with the views and needs of the outlying parts of the empire, by coming into actual contact with the colonial delegates, and discussing with them matters of common interest. Further extension was given to the movement by the decision to hold some of these congresses in the colonies, the first being at Montreal in 1903.

Congresses of Chambers of Commerce of the Empire.

The home organization of Chambers of Commerce is supplemented by a few British Chambers which have been established in foreign countries. These institutions are self-supporting, and not, as seems often to be thought, branches of or subsidized or controlled by home Chambers. The British Chamber of Commerce in Paris, which is the oldest of them, dates from 1873, and was originally established by British merchants in Paris for the defence of their own trade interests. Its scope soon extended, however, and it admitted to membership British firms trading with France although not resident in France, and in course of time became representative of general British commercial interests in the French markets. It advises British firms with regard to the interpretation and application of French commercial and customs laws and regulations; takes up their cases with the French Customs authorities when difficulties arise; gives information as to the standing of French houses; and defends British and colonial interests generally in France. It is kept up solely by the subscriptions of its members, those resident in Paris paying £4, and those resident abroad £2, per annum. The scanty support which the home trade has given to such institutions has prevented their growth in foreign countries, and whilst the French have thirty-eight Chambers looking after their interests abroad, British Chambers are to be found only in Paris, Nice, Alexandria, Cairo, and Constantinople. In Brussels, an Anglo-

British Chambers abroad.

American Chamber jointly represents British and American interests. The following countries are represented in London by Chambers of Commerce, viz., Austria-Hungary, Belgium, France, Italy, the Netherlands, and Spain. The Italian Chamber is the only one which has sought incorporation under the Companies Acts, and is also the only one which is a member of the Association of Chambers of Commerce of the United Kingdom. The United States are represented in England by the American Chamber of Commerce in Liverpool (see p. 396). The foreign Chambers in London have joined in forming an Association of Foreign Chambers of Commerce which does, to a certain extent, for them what the Association of Chambers of Commerce of the United Kingdom does for the home Chambers.

Foreign Chambers in England.

Commercial organization in the Colonies is very much on the same footing as it is in the United Kingdom. The most representative associations are the Chambers of Commerce, whose constitution and functions are similar to those of the British Chambers. In *Canada* the Chambers, which are also sometimes called Boards of Trade, after the American custom, are about sixty in number, the most important being the Montreal and Toronto Boards of Trade and the Quebec Chamber of Commerce. The Canadian Chambers have no association, but hold periodical conferences. There is, in addition, the Canadian Manufacturers' Association, with headquarters in Toronto and branches in all the provinces, which incorporates all the associations of manufacturers in the Dominion. Its meetings, which are held annually in various cities, are frequently attended by ministers and representatives of Government departments. The *Australian* Chambers of Commerce, which number about thirty, have joined into an association called the General Council of the Chambers of Commerce of the Commonwealth of Australia. The Australian Chambers are generally considered to represent the interests of importers and of general merchants, and to incline as a rule towards a free-trade policy. Their influence is counterbalanced by that of the Chambers of Manufactures, the most important of which are those of Adelaide, Melbourne, and Perth, to which must be added the National Agricultural and Industrial Association of Queensland, whose headquarters are at Brisbane. The Chambers of Manufactures have been very active in the promotion of technical and commercial education, and have founded valuable libraries and museums, of which those at Adelaide are said to be the best organized. In *New Zealand* there are some fifteen Chambers of Commerce. At a conference held in 1902 they practically decided to form an association after the Australian model. In *South Africa*, Cape Town, Kimberley, Port Elizabeth, Johannesburg, Pretoria, Durban, and Bulawayo have important Chambers. The South African Chambers are joined in a Federation of Chambers of Commerce of South Africa. In the *West Indies* the Jamaica and the Trinidad Chambers are the most important. The *Indian* Chambers of Commerce, which are not federated, are for the most part very important and influential bodies, which the Government of India often consults. The Bombay and Madras Chambers, and the Bengal Chamber at Calcutta, have a predominant voice in the organization of Indian trade, notably in the settlement of the regulations of the cotton trade, and the first and last are intimately connected with the administration of the ports of Bombay and Calcutta. There are Chambers at Rangoon and Karachi. The Colombo Chamber represents Ceylon trade; there is a Chamber at Singapore for the Straits Settlements; one at Hong Kong; one in Shanghai; one in Mauritius; one at Valetta, for Malta; one at Gibraltar; one in Georgetown, for British Guiana; and four in West Africa, viz., at Cape Coast, Accra, Sierra Leone, and Lagos.

Colonial Chambers.

With the exception of Australia none of the Colonies was in 1902 represented in London by Chambers of Commerce proper, and the Australian Chamber had only lately been established. The West India Committee and the Ceylon Association look after the commercial interests of their respective countries, whilst the United Empire Trade League, the British Empire League, and the Imperial Trade Defence League endeavour to promote inter-Imperial trade.

(*b*) *Associations representing Particular Trades.*—Associations representing particular trades are almost innumerable. Chambers of Shipping and Shipowners' Associations occupy the foremost place among them, for shipping is of such moment in the economic life of the empire that, although more representative of a particular interest than of the general commercial interests of the country, they have attained a position of influence which no other body limited to one particular trade has succeeded in obtaining. The London General Shipowners' Society, the Liverpool Shipowners' Association, the North of England Shipowners' and Steamship-Owners' Associations may be mentioned as representative. In shipping centres of secondary importance the shipping interests are taken charge of by the local Chamber of Commerce, which styles itself Chamber of Commerce and Shipping; this is the case in Bristol, Grimsby, Hull, Ipswich, and Cork. The various Chambers of Shipping and Shipowners' Associations joined forces in 1878 in order to establish the Chamber of Shipping of the United Kingdom, which does for them what the Association of Chambers of Commerce does for Chambers of Commerce. It is divided into two sections, viz., the Shipowners' Parliamentary Committee, which watches all public Bills affecting British merchant shipping and looks after shipping interests in Parliament, and the Documentary Committee, which deals with charter-parties, bills of lading, berth notes, and other maritime documents, settles forms to be used, &c. The development of the mining industry led to the foundation some years ago of the London Chamber of Mines, which serves as an intermediary between mining interests on the one hand and the British commercial and financial public and the Government and Parliament on the other. This Chamber was supplemented in 1897 by the London Chamber of Rhodesia, whose membership is restricted to companies interested in the territories of the British South Africa Company, and having a working capital exceeding £20,000. It acts as the London correspondent of the Incorporated Chamber of Mines of Rhodesia, and defends and promotes Rhodesian land and mining interests. The Chambers of Mines are of colonial origin. In Australia they are to be found in Melbourne, Charters Towers, Perth, Coolgardie, and Kalgoorlie; in South Africa, at Cape Town, Kimberley, Johannesburg, and Bulawayo; and in Canada the Central Canada Chamber of Mines looks after mining interests. The Iron and Steel Institute affords a means of communication between members of the iron and steel trades, and its general meeting is an event of importance. This meeting is sometimes held abroad on the invitation of foreign associations, when technical papers are read, and discussions take place concerning especially processes and improvements connected with the manufacture of iron and steel. One-fourth of the members of the Institute are foreigners. Of the associations of firms connected with the iron trade, the British Iron Trade Association is one of the most powerful. The nature of the other associations is sufficiently indicated by their titles, and we cannot do more than give the names of very few of them. In addition to those mentioned in connexion with the London Chamber of Commerce, there are the Cotton Association, the Drapers' Chamber of Trade, the Fish Trade Association, the Sugar Refiners' Committee, various tea planters' associations, the Oil Seed Association, the Petroleum Defence Committee, the Mansion House Association on Railway and Canal Traffic, &c., &c. Almost every trade has an association of its own, one of the most recently established being the Society of Motor Manufacturers and Traders, 1902. In addition to these, there are in almost every town of importance organizations known as Traders' or Tradesmen's Associations, which look after the interests of the retail trades. A number of these associations joined in 1897 to form a central organization called the National Chamber of Trade, which has its headquarters at Hull, and comprises fifty Traders' Associations and some 300 individual members. The National Chamber federates, whenever possible, the various Traders' Associations in a town in a Chamber of Trade for the town, which is afterwards incorporated in the National Chamber.

(*c*) *Trade Protection Societies.*—These seem to be, on the whole, more ancient bodies than Chambers of Commerce. In the early part of the 19th century they were already strongly organized, especially in the West Riding of Yorkshire. Outside of that district the Dublin Society was the most important. In 1902 they numbered 115 throughout the United Kingdom.

The Manchester Guardian Society, which dates from 1826, occupies a position of special prominence in the Midlands, and may be taken as the model of such associations. Its objects are—the making of private inquiries as to the respectability and credit of traders; the detection and exposure of swindlers; the collection of debts; the winding-up of insolvent estates; the issue of notices of bills of sale, judgments, bankruptcies, &c.; and generally the improvement of laws and regulations affecting trade. The Society charges an ordinary subscription of only 10s. per annum, which entitles members to all privileges, and to be supplied with confidential information as to the standing of firms at the rate of 6d. each for the first fifty inquiries in each year, and 1s. each for inquiries above that number. The collection of debts is done without commission and for fees on a moderate scale: for debts under £20, 1s.; above £20 and not exceeding £50, 1s. 6d.; and above £50, 2s. The Society has over 6000 members, and its usefulness may be gauged by the fact that it answers an average of 40,000 credit inquiries, represents members in over 300 bankruptcies, arrangements with creditors and liquidations, and is entrusted with the collection of debts amounting to about £150,000 every year.

Manchester Guardian Society.

Trade Protection Societies formed themselves, as early as 1848, into an Association, with offices at Nottingham, which was at first an Association of Secretaries, but in 1865, when it included seventeen societies, was transformed into an Association of Societies. The number of affiliated bodies in 1902 was 82, their membership varying from 6000 in the largest to 25 in the smallest. The Association issues a quarterly journal called *The Trade Protection Journal*.

Association of Trade Protection Societies.

(*d*) *Non-Representative Organizations.*—Apart from representative institutions, certain organizations have grown up which have proved of great value to the commercial community, owing to the means of information which they have placed at its disposal. It is sometimes difficult to draw the line between private businesses and those which, whilst remaining private corporations, perform duties and render services which in other countries are performed and rendered by public bodies.

Commercial Intelligence Bureau, Limited.

The most noteworthy of these is the Commercial Intelligence Bureau, Limited, which was established in 1900 through the efforts of Mr Henry Sell, for the purpose of rendering to British manufacturers and merchants services similar to those which the Philadelphia Commercial Museum was rendering to American commercial men in placing them in relation with likely foreign customers of standing in their own trade. This Bureau is, it is true, in the nature of a private concern, conducted on ordinary business lines, and distributing dividends to its shareholders, but the public importance of the work which it is doing and the efficient state it has reached render it advisable to explain its method, which is still but imperfectly understood by the public. Its work is limited to the compilation and supplying of Index File Cabinets, which place before manufacturers and merchants seeking facilities in export a list of trustworthy foreign buyers in particular lines, and *vice versâ* supply foreign buyers with lists of British manufacturers. These Cabinets—each of which is devoted to a particular trade or branch of trade, as the case may be—are filled with cards, arranged alphabetically from the names of the firms inscribed on them, and giving, besides name and address, branches, and London office if any, date of establishment, amount of capital, class of business, and if buyers a detailed and accurate list of the goods bought, and if manufacturers the list of goods manufactured and supplied. Each Cabinet is also provided with an index classification by countries and one by articles bought or sold. The Bureau is not an agency to obtain information as to the standing and credit of firms, but it guarantees that only firms of recognized good standing are allowed to figure in its Cabinets, and the statements on each card are checked by the firm interested before the card is put into circulation. Thirty trades, each with its own subdivisions, are included in the collection of Cabinets. Cabinets are supplied to subscribers and kept up to date for an annual subscription which varies in accordance with the importance of the trade, but generally ranges from £5, 5s. to £10, 10s. In addition to this, the Bureau keeps collections of its Cabinets in public places of resort of merchants abroad, such as Bourses and Exchanges, Chambers of Commerce, British Consulates, &c., where they can easily be consulted by foreigners desirous to do business with the United Kingdom. This is in imitation of the practice inaugurated by the Philadelphia Commercial Museum. The Bureau has opened a similar establishment in Paris, to do for French trade what it does for British trade.

B. *State Departmental Organizations.*

Although the British Government allowed commercial organizations within its jurisdiction to grow independently of official control, it does not follow that it took no interest in the protection and promotion of British trade and the dissemination of commercial intelligence. As long ago as the reign of Charles II., the body which is now the British equivalent of what is known in most countries as the Ministry of Commerce, viz., the Board of Trade, was established. In addition to this, other Government departments, such as the Foreign and the Colonial Offices, within whose purview commercial matters often came, took a fairly active interest in them. The commercial jurisdiction of the Board of Trade does not extend beyond the limits of the United Kingdom, but the Foreign Office, through the negotiation of commercial treaties and by means of the consular body, came into touch with the larger interests of international trade. It was frequently appealed to, both by private firms and by Chambers of Commerce and other associations, to undertake the defence of British trade abroad against injurious action of foreign governments and administrations. With the development of the Colonies, the Colonial and India Offices also found themselves called upon to act, to a certain extent, as guardians of commercial rights and channels for the dissemination of commercial intelligence. They have now departments specially entrusted with commercial affairs, but it is only within recent years that their commercial work has become systematized, and that efforts have been made to render it really effective in view of the magnitude of the interests involved.

So long as Great Britain enjoyed unquestioned commercial supremacy, things were allowed to go on without serious attempts being made to improve the means of official action proportionately with the extension of international trade. But when competition, especially German and American, began to displace British goods from foreign markets, and when the British trader began to realize that his supremacy was threatened, he noticed the efforts which were being made by foreign governments for the promotion of trade, and he came to the conclusion that the British Government was not doing anything for him. This was of course an exaggeration, but it was perhaps necessary that the outcry should be exaggerated in order to impress upon the home Government the necessity of improving its methods with the requirements of the times.

Consular service.

Complaints were especially loud against the consuls, who were accused of systematically disregarding commercial interests, whilst their American, German, French, and Belgian colleagues did not consider it below their dignity to take advantage of their position in order to promote the trade of the country they represented. British Consular Reports were also unfavourably compared with those issued by foreign consuls, notably the American, and the mode of their publication, which, at one time, consisted in waiting for all the reports to come in in order to publish them in one or two big volumes, was condemned as rendering the information they contained practically of no value when it reached the public. The result was that, in 1886, when Lord Rosebery was Secretary of State for Foreign Affairs, he instructed the Under-Secretary of State, Mr Bryce, to carry out, in view of the action of Chambers of Commerce, an extensive inquiry into the question of consular action in international trade, with the object of facilitating the dissemination of commercial intelligence, and of giving British consuls detailed instructions with regard to their duties in commercial matters and to the help to be given by them to British merchants. In consequence of Mr Bryce's recommendations, instructions were issued to the consular service which, for the completeness and fairness with which they deal with the subject, can hardly be equalled by anything that has been published in foreign countries, and which have frequently been quoted by foreign representatives in England as models which might advantageously be followed (see Parliamentary Paper, Commercial, No. 16, 1886). The preparation of Consular Reports, however, continued to be most unfavourably criticized, and frequent instructions were issued by the Foreign Office in regard to them, notably in 1888, 1889, 1891, and 1893. In 1895, Lord Kimberley issued a further circular, embodying the recommendations of Chambers of Commerce with regard to the kind of information to be given in Consular Reports, and the manner in which it should be set forth. The whole question was raised again in 1896, when, as the result of lengthy communications between the Foreign Office on the one hand and the Association of Chambers of Commerce and the London Chamber on the other, and under the incentive of the action which had just been taken by Mr Chamberlain as Secretary for the Colonies (see below), fresh instructions were sent to British consuls, reiterating with especial emphasis Lord Rosebery's instructions of 1886, and urging them to be particularly careful, not only in the preparation of their reports, but in reporting without delay, and even by telegraph, if advisable, matters which might be of interest to the British commercial community, and in giving to British traders and their agents all the help and information in their power (Parliamentary Paper, Commercial, No. 5, 1897).

From a perusal of these instructions, it is plain that if the British consular body does not render commercial services equal to those rendered by the representatives of certain other nationalities, the fault does not lie in the instructions furnished to them. If the best of instructions have been ineffectual, the reason is that sufficient care has not always been exercised in the selection of British consuls, and that the following practices, among others, have too often been indulged in, viz., appointments through influence, and without regard to qualifications; non-insistence upon commercial knowledge of a real and serious nature; frequent selection of men who have been brought up in circles out of touch or sympathy with commercial aims and commercial men, and who consider it below their dignity to have anything to do with trade matters; appointment of foreigners; too frequent appointment of unpaid trading consuls, who cannot always afford the necessary time or bring the necessary impartiality to the discharge of their functions; and distribution of appointments without due regard to

commercial importance of districts, inland manufacturing centres being too often sacrificed to unimportant seaport towns.

The consular service has of late years been supplemented by the appointment of commercial attachés, who in 1902 were seven in number, viz., one in Paris, for France, Belgium, and Switzerland; one in Berlin, for Germany, Denmark, Holland, and Sweden and Norway; one in Madrid, for Spain and Portugal; one in Constantinople, for European and Asiatic Turkey and Bulgaria; one in St Petersburg, for Russia and Siberia; one in Vienna, for Austria-Hungary, Italy, and Greece; and one at Shanghai, for China and Japan. No other country, with the exception of Russia, seems to have similar commercial representatives. The posts are of comparatively recent creation, the first commercial attaché having been the late Sir Joseph Crowe, who was appointed to Berlin and Vienna in 1880. The second post, which was to St Petersburg, was created in 1887, and the third one to Paris in 1889. The attachés' duties are to avail themselves of every possible source of information in regard to commercial questions within their jurisdiction; to prepare an annual report, and, whenever advisable, special reports, on matters of interest to trade and industry; to help consuls with advice; to pay special attention to all tariff questions and regulations; to follow the proceedings of legislatures within their jurisdiction, and furnish information as to any bills, or laws, or parliamentary discussions and papers affecting trade matters; to give assistance to British merchants and to British Chambers of Commerce, and to endeavour to meet their wishes so far as they properly can, "and, although not expected to act as agents or commercial travellers for private firms, or to push their particular business, yet to render them substantial assistance in the pursuance of legitimate enterprise as far as possible"; to cultivate friendly relations with the heads of the department concerned with industry and commerce, and also with the heads of the great manufacturing or commercial firms within their jurisdiction; and, in addition, to report upon matters connected with mining and industrial concessions, labour and sanitary questions, railways and canals, trade marks and patents, bounties and subsidies, technical and commercial education, improvements in industrial methods and machinery, the state of agriculture, &c. (Instructions of 1896).

Commercial attachés.

The pressure exercised by the Chambers of Commerce upon the Government led to the appointment in 1897 of a Departmental Committee on the Dissemination of Commercial Intelligence, which was composed of representatives of the Board of Trade, the Foreign, Colonial, and India Offices, and the Treasury, and the presidents of the Association of Chambers of Commerce and of the London and Manchester Chambers, and which was charged with considering means of more adequately supplying traders with commercial information, of improving consular and colonial reports, and with reporting on the advisability of appointing commercial agents to the Colonies and establishing a Commercial Intelligence Office. The chief result of the committee's recommendations was the establishment of the Commercial Intelligence branch of the Board of Trade, of which Mr T. Worthington, who had acted as special commissioner to South America, was appointed principal. This branch was entrusted with the centralization of the commercial information received by the various Government departments, and the dissemination of this intelligence. It has the power to send commercial missions abroad for the purpose of inquiring and reporting upon trade matters, and can order the preparation of special reports upon particular trades or industries, collects and exhibits samples and patterns whenever advisable, and supplies general information in connexion with foreign customs and shipping duties and regulations, fees, trading licences, &c. It publishes the *Board of Trade Journal* weekly. Attached to the branch is an Advisory Committee, composed of representatives of the various Government departments and of the Association of Chambers of Commerce, who meet in private once a month, and hold office for a period of five years.

Commercial Intelligence branch of the Board of Trade.

The scope of the Commercial Intelligence branch was further increased, and its means of action strengthened, by the transfer of the Imperial Institute to the Board of Trade, which was effected in 1902 by the passing of a private Act of Parliament. The Commercial Intelligence Department and the Colonial and Indian Sections of the Institute, with their complete and efficient organization, are now controlled by the Commercial Intelligence Branch of the Board of Trade, but the good work which they did when the Institute was a private corporation deserves special mention. They endeavoured to develop trade with the Colonies by organizing a valuable and complete system of colonial trade information at a time when no such thing was in existence in London, and by arranging collections of raw materials and produce, which afforded a comprehensive representation of natural wealth, and of its practical value and application to various arts and manufactures. The Research Department, whose duty it was to make experiments with samples of raw products in order to test their capacities and their uses, has also rendered great services to British commerce; as have also the expert referees, who experimented with new or little-known materials, and expressed competent opinion as to the probable demand for and marketable value of product. The Imperial Institute has two City offices—one in Cannon Street, which was opened for the purpose of affording business men general information, and of providing a proper office for the translation of documents in Eastern or little-known languages; the other in Eastcheap, for organizing exhibitions of colonial products, and for forming a Museum of Samples of Colonial and Indian Raw Materials, which could conveniently be resorted to by City men.

Imperial Institute.

Official means of obtaining information in connexion with the Colonies and India are not on so satisfactory a basis as in the case of foreign countries. There are no representatives of the British Government in those parts of the empire whose duty it is to report upon trade prospects, and to render home manufacturers and merchants the services which are performed in connexion with foreign trade by commercial attachés and by the consular service. The Colonial Office publishes occasional reports concerning the Colonies, but they can hardly be said to be even as satisfactory as the consular reports, and they are not so freely distributed as the latter. Too often the British commercial community has to go, for commercial information of any value concerning British Colonies, to the reports issued by American, French, or Belgian consuls.

Colonial and Indian intelligence.

The self-governing Colonies are, however, represented in London by Agents-general, whose duties are mainly of a commercial nature, and who are especially entrusted with making the products of the Colonies known in England, looking after the interests of the Colonies in the matter of shipping arrangements and rates of freight, cable communications and rates, tenders for public works, &c. Their expenses and salaries are fixed and paid by the Government of the Colony they represent. The following Colonies have agents-general in London, viz., Canada, whose representative is styled High Commissioner; New South Wales, Victoria, South Australia, Queensland, West Australia, New Zealand, Tasmania, Cape Colony, and Natal. The Canadian provinces of Nova Scotia and New Brunswick have separate agents-general. Canada has also commercial agents in Liverpool, Cardiff, Glasgow, and Dublin; in Sydney, Cape Town, Kingston (Jamaica), St John (Antigua), St Kitts, and Port of Spain; and in Paris, Antwerp, Christiania, and Buenos Aires.

Agents-general.

The commercial interests of the Crown Colonies are in the hands of the Crown agents for the Colonies, who, however, are not colonial representatives like the Agents-general, but home Government officials, and whose duties are chiefly connected with the public works of the Colonies, with shipping contracts, port and dock regulations, and similar quasi-administrative functions. The India Office looks, to a certain extent, after the commercial interests of India, but from both the British and Indian commercial point of view the system in force in 1902 was very inadequate.

Crown agents.

When Mr Chamberlain took office for the first time as Colonial Secretary, in 1895, he was so much impressed by the results of the Congress of Chambers of Commerce of the Empire, which had taken place in the previous year, and by the statements there made as to the displacement of British goods from colonial markets, that he entered into communication with the London Chamber of Commerce, which had organized the congress, requesting it to make suggestions for the drafting of a despatch to colonial governors, asking for information as to the extent to which foreign competition displaced British goods from colonial markets, the causes of this displacement, and the means which might be adopted to induce colonial buyers to purchase British-made articles in preference to foreign manufactures. The despatch went most minutely into the question, and asked for specific and detailed information with regard to prices and conditions of payment by British and foreign exporters, suitability of goods for the market, native preferences, quality, finish, packing, &c. A list of sixty-eight principal articles was appended to the despatch, with a request that particular attention should be paid to them. The governors were at the same time requested to send samples of the foreign-made articles which sold in colonial markets in preference to English-made ones, and to affix to each sample the price at which the article was retailed to the public.

Colonial trade.

The samples were sent to the London Chamber of Commerce, where they were exhibited for some time, and were subsequently sent for exhibition to various Chambers of Commerce throughout the United Kingdom. Wide publicity was at the same time given to the replies received from the governors, and leading firms in each trade were requested to send representatives to examine the samples, and to give for publication a report as to what they thought of them, of the price at which they sold, and of the means which British manufacturers should adopt to oust them from colonial markets. The burden of the reports was typically British. There was a general consensus of opinion that the articles of which samples had been sent were, in the main, so poor that no British firm would lower

itself to manufacture them, and that if the colonials preferred them to solid and thorough and expensive British-made articles, they were not worth catering for. General surprise was, nevertheless, expressed at the excellence and marvellous cheapness of American ironmongery, and the skilful and artistic way in which foreign goods in general were packed was contrasted with the rough-and-ready manner in which British-made articles were put up.

These matters led to the conference of Colonial Premiers with the Colonial Secretary at the time of Queen Victoria's Jubilee in 1897, when commercial questions affecting the Colonies and the mother country were under consideration. This first interchange of opinions was followed in 1902 by another similar conference, which took place on the occasion of the visit of the Colonial Premiers for King Edward's coronation.

II. United States of America.

A. *Commercial Associations.*

American trade organizations have been developed mainly on the lines of the British system. Of the associations which come within the scope of this article, the most important are the Chambers of Commerce, which in certain cases are called Boards of Trade. Theoretically there is a distinction between the two, Chambers of Commerce being entrusted with the protection of general commercial interests, especially in connexion with foreign trade, whilst Boards of Trade look after local commercial questions. But in practice the difference is of no importance, as Chambers of Commerce take cognizance of local as well as international trade matters, and the Boards of Trade in no way limit the sphere of their activity to purely American questions.

The New York Chamber.

The oldest American commercial organization is the New York Chamber of Commerce, which was founded in 1768, and incorporated by royal charter in 1770. In the words of its charter, its object was "to carry into execution, encourage, and promote by just and lawful ways and means such measures as will tend to promote and extend just and lawful commerce." It was the prototype of all the other Chambers of Commerce and Boards of Trade which have since been established in the United States, and which are said to exceed 1000 in number.

The National Board of Trade.

American trade organizations are associated in a National Board of Trade, which corresponds to the Association of Chambers of Commerce of the United Kingdom. The objects of this institution are to secure unity and harmony of action in reference to commercial questions, and to obtain, through its representative character, more satisfactory consideration of the matters which it brings under the notice either of the Federal Government or of the local State administrations. The expenses of the National Board of Trade are defrayed out of a fund formed by the subscriptions of the various associations belonging to it.

American Chambers abroad.

The Americans have a number of Chambers of Commerce established in foreign countries. They started the first institution of this kind so long ago as 1801, when the American Chamber of Commerce in Liverpool was established. This chamber was in 1902 the only one representing American commercial interests in the United Kingdom, there being no association of this nature in London. The American Chamber of Commerce in Paris is one of the most active, important, and representative foreign associations on the Continent. In some places where neither the American nor the British element is strong enough to maintain separate associations (notably in Brussels), they have joined hands to support an Anglo-American Chamber of Commerce, which is found to work fairly satisfactorily.

Commercial museums.

The American Commercial Museums, although of recent foundation, have attracted much notice owing to the practical and business-like manner in which they are conducted, and are considered to be among the best equipped institutions of this nature. They are two in number, one in Philadelphia and the other at San Francisco. The Philadelphia Museum, which came first and is better known, was established by an ordinance of the municipality in 1894, and is supported by subscriptions and by municipal subsidies, administered by a board of trustees, who are appointed for life and serve without remuneration. The work of the museum is supervised by an advisory board, composed of representatives of the principal commercial organizations in the United States. Its objects are to assist American manufacturers and merchants in securing wider foreign markets for their products, to aid them in forming connexions abroad, and to bring foreign buyers in touch with them. One of the chief ways in which this is done is by means of an index file of foreign customers supplied to American manufacturers, and *vice versâ*, on the principle which has been put in practice in London by the Commercial Intelligence Bureau, which, by the way, is an offshoot of the Philadelphia Museum (see p. 394). In addition to the regular service to members, the Museum also maintains abroad, in forty-five different cities, index files covering sixty American trades or trade divisions, containing the names of American manufacturers of standing, with full particulars of their various lines of manufacture. These files are generally entrusted to Chambers of Commerce, or similar commercial institutions, and are placed gratuitously at the disposal of foreign manufacturers and merchants. The Philadelphia Museum has also a most valuable library and a museum of samples, which it has endeavoured to make as complete and representative as possible, and to keep strictly up to date. It seems, however, that the policy of keeping such samples is open to question. At any rate, the use which has been made of the Philadelphia collections has not been such as to warrant the expense and care which they entailed, and latterly this feature, which was at one time the most prominent, has been allowed to drop into the background, as happened also in the case of the Vienna Handelsmuseum. The energies of the institution are now especially directed to the services which it is in a position to render its members in connexion with foreign markets, by finding them desirable houses with which to do business and supplying information to foreign firms desirous of doing business with America. The American Commercial Museums, in addition to the subsidies which they receive from municipalities and from commercial associations, have also subscribing members, who pay 100 dollars per annum to be entitled to all the services which the museum can render, and 25 dollars if they desire only the index file in their particular line of business.

B. *State Departmental Organization.*

The American state organization for dealing with commercial matters lacks the theoretical completeness of the organization of most European states, but is nevertheless found to give satisfaction. Official control is exercised through various bureaus placed, for the most part, under the Treasury Department. The most important of these are: the Interstate Commerce Commission, which deals with matters affecting the inland trade; the Industrial Commission, which looks chiefly after manufacturing; and the Fishery Commission. There is no Ministry of Commerce, nor any department centralizing the commercial functions fulfilled in England by the Board of Trade and abroad by Ministries of Commerce. Foreign commercial matters come within the cognizance of the Bureau of Foreign Commerce, a section of the State Department which also controls the consular body, and sees to the publication of their reports and to the dissemination of foreign commercial intelligence. The State Department corresponds to the British Foreign Office.

An institution deserving of special mention is the Bureau of American Republics, which was established in 1889, as a result of the Pan-American conference called together in that year by the late Mr James G. Blaine, then State Secretary. This Bureau, which has its office in Washington, is supported by a contribution from all the republics of North, Central, and South America, which is fixed at the rate of 1000 dollars a year per million inhabitants. Its object is the dissemination of trustworthy commercial information concerning the republics of the American continent, and in pursuance of this object it has issued a large variety of publications, handbooks, compilations showing the trade usages, commerce, industry, tariffs, commercial and quasi-commercial laws, &c., of each republic, as well as an elaborate *Code of Nomenclature*, or dictionary of the business terms in use in the different republics, published in English, Spanish, and Portuguese. It has also issued a *Commercial Directory of the American Republics*, and publishes a monthly bulletin.

Consular service.

The American consular service has been frequently pointed out as a model to be followed in connexion with commercial matters. America, contrary to the European practice, has no *consuls de carrière*. Her consular representatives are appointed for a period of, as a rule, four years, and are selected in preference from commercial circles. Their work, as compared with that of British consuls, is rather limited, and they have nothing to monopolize their time like the shipping interests with which the British consular body is entrusted in most countries. They have, in consequence, more opportunities of devoting themselves to the purely commercial side of their duties, and as most of them are business men, it is naturally towards this side that they first turn. As a body, they have displayed a decided business instinct, which has enabled them to secure the kind of information

especially wanted by the American commercial world, and their reports have been particularly remarkable for their terseness and for the practical way in which they conveyed information. Since 1898, the Bureau of Foreign Commerce issues consular reports daily, as fast as they are received, and circulates them in advance sheets, printed on one side of the paper only, like printers' proofs. They are afterwards republished in permanent form.

The American consular body, which numbers about 400 members, and is exclusively composed of American citizens, is distributed according to the commercial importance of towns. Important inland manufacturing districts are not sacrificed to more or less insignificant seaport towns, as is too often the case in the distribution of the British consular body.

III. France.

A. *Commercial Associations.*

The French Government was the first to elaborate a regular system of trade organizations, which it endeavoured to make as complete as possible. This system as it exists at present comprises :—

(*a*) Chambers of Commerce;
(*b*) Consultative Chambers of Arts and Manufactures; and
(*c*) Syndical Chambers of Trade and Industry.

(*a*) *Chambers of Commerce.*—Chambers of Commerce owe their origin to the city of Marseilles, where, in 1599, the Town Council, which had hitherto looked after the commercial interests of the city, found it no longer possible to combine commercial with municipal functions, and established an association which it called the "Chamber of Commerce" to take up the commercial part of its duties. This seems to be the first time that the title was used. The new chamber soon became a most important body, and in 1650, during the minority of Louis XIV., *lettres patentes* were granted to it. It settled the law merchant and the customs of the port, was entrusted with the appointment of consuls and the control of French consulates in the Levant, fitted out expeditions against corsairs, owned fleets, sent embassies to the Barbaresque countries, organized commercial missions, &c. Its ordinary budget, at one time, amounted to over one million livres. Louis XIV. conceived the idea of a system of organizations which, whilst not being allowed to become so dangerously powerful as that of Marseilles, would nevertheless be useful in other towns, and in 1700 he caused an *arrêté* to be published, ordering the creation of Chambers of Commerce, which were entrusted with the nomination of deputies to the Royal Council of Commerce which had just been created in Paris. Chambers were consequently established in Lyons, Rouen, Toulouse, Montpellier, Bordeaux, La Rochelle, Lille, Bayonne, Amiens, &c. These bodies, however, did not exercise much influence under the monarchy. Including the Marseilles Chamber, they were suppressed, with all trade gilds and other trade associations, in 1789. Napoleon re-established the Chambers by decree of the 24th December 1802, and endowed them with a constitution similar, in essential particulars, to the one they have at present, which has served as a model for Chambers of Commerce on the Continent, but he submitted them to a uniform and narrow administrative jurisdiction which practically deprived them of all initiative, and rendered them almost useless as representative commercial associations.

Origin.

They are now regulated by the law of the 9th April 1898, which codified, altered, and completed previous legislation on the subject. Under this law, Chambers of Commerce can only be established by a decree countersigned by the Minister of Commerce, upon the advice of the Municipal Council of the place where the Chamber is to be, of the General Council of the department, and of the existing Chambers of Commerce of the district. The members of Chambers of Commerce used to be elected by the "Notables Commerçants," who were a body of commercial electors selected by the prefects in accordance with the provisions of the Code of Commerce. They were abolished by law in 1871, but those who were then entitled to the designation still continue to use it, which explains the words "Notable Commerçant," so puzzling to foreigners in French commercial directories and on French business cards. At present, commercial houses paying *patente*—which is a special tax upon people engaged in trade —elect the members of the Chamber, the number of whom is fixed for each Chamber by the Minister of Commerce. It cannot be less than nine nor more than twenty-one, except in Paris, where it may be thirty-six. Members are elected for six years and retire by thirds every two years, but are re-eligible at all times. They elect, subject to the approval of the Minister of Commerce, their officers, who cannot remain in office more than three years. Attendance at least once every six months is compulsory under penalty of expulsion. It is paid for at all times by a *cachet* or token, ranging in value from ten francs to twenty francs. There are 142 Chambers of Commerce in France and in the French colonies. French Chambers are bound to give their services gratuitously, and their income is derived from a special addition to the *patente* paid yearly by commercial houses. Such other establishments as they may control have separate budgets, and these, as well as the Chambers' budgets, have to be examined and approved every year by the Minister of Commerce.

Constitution.

Their functions, which are consultative and administrative, are set out in Part II. of the Law of 1898. The Government is bound to take their opinion regarding the regulation of commercial usages, the establishment of public institutions of a commercial or financial nature, and of tribunals of commerce, the improvement of transport and communications, the application of laws of a local character, the sale price of prison-made goods and the tariff for prison labour, and local public works, and loans or taxation in connexion therewith. On the other hand, they are allowed to submit observations to the Government, without being asked, on proposed changes in the commercial or economic legislation of the country; on customs tariffs and regulations; on railway, canal, and river rates; and on transport regulations. As regards their administrative functions, they may be authorized to establish and administer such institutions as bonded warehouses, public sale-rooms, fire-arm testing establishments, conditioning rooms for wool, silk, textiles, paper, &c., commercial, professional, or technical schools and museums, &c. They may be granted concessions for public works, and may undertake the carrying out of public services, especially in regard to the ports, docks, canals, and navigable rivers in their district, and be authorized to issue loans for the purpose. They have to ascertain the local prices of goods for official quotation, to issue certificates of origin and commercial travellers' certificates, and to submit every year to the Minister of Commerce a list of names of experts to form the Board of Experts called upon to decide difficulties arising between the customs authorities and importers of foreign goods.

Functions.

Previous to 1898, it was illegal for Chambers of Commerce to hold joint meetings for the discussion of matters of public interest, and they were not even allowed to correspond or consult in any way, except through the medium of the Minister of Commerce. The new law relaxed to a certain extent this prohibition, by authorizing direct correspondence and permitting Chambers in a district to meet for the joint consideration of questions affecting their district, but for no other purpose. Such a thing as an Association of Chambers of Commerce, or a general meeting of Chambers for the consideration of questions such as are raised at the general meetings of the Association of Chambers of Commerce of the United Kingdom, has always been and is still illegal in France. Chambers of Commerce which fail to comply with the law, or which make themselves objectionable, may be dissolved by decree on the proposal of the Minister of Commerce.

When, in 1873, British merchants in Paris started a British Chamber of Commerce in the French capital, the French Government looked rather askance at the new venture, and M. Léon Say, when Minister of Commerce, even threatened it with forcible dissolution unless the title "Chamber of Commerce" was dropped. This demand was not ultimately pressed, and the services rendered by the British Chamber soon opened the eyes of the French Government to the advantages which they might derive from the formation of similar institutions to represent French commercial interests abroad. In 1883, the Minister of Commerce started the organization of such Chambers, which endeavoured to combine to a certain extent the French and the British systems. These Chambers, of which the French Chamber in London is the oldest and may be taken as the model, belong to the British system in so far as they are formed by the election of members who pay a yearly subscription, and are not limited in number, have no administrative duties, and are not submitted to the restrictions imposed by the French law upon such bodies. They belong to the French system in so far as they receive a subvention from the French Government, as the sanction of the French Minister of Commerce is required for their establishment, and as the Government is represented upon them by the French consul of the locality, who is *ex officio* honorary president. The amount of the subvention depends upon the importance of each Chamber and the requirements of the locality. A sum of about 100,000 fr. is voted every year in the French budget for the purpose. The French Chamber in London gets between 6000 and 7000 fr., and the others in proportion. There were in 1902 thirty-eight such Chambers in existence.

French Chambers of Commerce abroad.

Foreign commercial interests are represented in Paris by seven foreign Chambers of Commerce, of which the British Chamber is the oldest. The others are the American, Austro-Hungarian, Belgian, Italian, Spanish, and Russian Chambers. In 1896, these Chambers formed themselves into an Association of Foreign Chambers of Commerce, but the French Government gave it to be understood that, as they did not allow associations of French Chambers, they could not treat foreign bodies more favourably, and the Association had to be dissolved.

Foreign Chambers of Commerce in Paris.

(*b*) *Consultative Chambers of Arts and Manufactures.*—These institutions, organized somewhat after the model of Chambers of Commerce, represent manufacturing and industrial interests. They were established by Napoleon I. in 1803, and formed part of the complete system of commercial organizations which he intended to give France. They are now regulated by decrees of 1852 and 1863, and are composed of twelve members elected for six years by merchants and manufacturers inscribed upon an electoral list specially drawn up by the prefects. These Chambers, of which in 1902 there were forty-eight in existence, are placed under the control of the Minister of Commerce, but instead of being kept out of the *patentes*, like Chambers of Commerce, they are supported by the municipality of the town where they are situated, which has also to provide them with offices rent free, and with clerical assistance. In addition to giving advice in connexion with manufacturing and industrial matters, they have to look after and report upon improvements in manufactures and machinery, new industrial processes, &c. They are especially useful in the preparation of local and international exhibitions. They are also entrusted with the nomination of the Consultative Committee of Arts and Manufactures, a body whose functions are to advise the Ministers of Commerce and Finance, as well as those of the Interior and of Public Works, as regards the regulation of dangerous trades and industries, patents and trade marks legislation, and the interpretation of customs regulations, notably in the classification of goods not specifically mentioned in the tariff. This power gives them great importance from the commercial point of view, and brings them into daily contact with importers and foreign merchants.

Constitution.

Functions.

(*c*) *Syndical Chambers of Trade and Industry.*—By the side of the official trade organizations, other associations have grown up, which, although regulated by law, are in the nature of voluntary and self-supporting bodies, viz., the Syndical Chambers of Trade and Industry. The repeal in 1884 of the law of 1791, which prohibited the formation of trade or professional associations, was the signal for the formation of those Chambers, which soon acquired great influence. A few Syndical Chambers existed before that date, the oldest, the Chamber of Master Builders, dating back as far as 1809, but they were only tolerated, and their existence, being illegal, was most precarious.

The Syndical Chambers, which are divided into Chambers of Employers and Chambers of Employed, are the official organs and representatives of the trade and professional syndicates authorized by the law of 31st March 1884, which was the work of M. Waldeck-Rousseau. Each syndicate has its separate Chamber. They may be established without Government authorization, but a copy of their rules and a list of their officials must be sent to the prefect. Membership is strictly limited to persons of French nationality. The only way in which the Government can dissolve them is by application to the courts of justice for an order of dissolution on the ground of infringement of the provisions of the law. In Paris, most of the Syndical Chambers have formed themselves into an association called the Union Nationale du Commerce et de l'Industrie—Alliance des Chambres Syndicales, which has built a hall in the Rue de Lancry in which they are all housed, and where one common staff of officials and attendants does the clerical and office work of all the Chambers. Another association, intended to take up the defence of the interests and rights of Syndical Chambers, has been formed under the title of Syndicat du Commerce et de l'Industrie—Syndicat des Chambres Syndicales. The Syndical Chambers are kept up by the subscriptions of their members, and have the right to hold real property, as have also the Associations of Chambers, which are kept up by subscriptions from the constituent Chambers.

Constitution.

According to the law which authorized their formation, the objects of the Syndical Chambers are exclusively "the study and defence of economic, industrial, commercial, and agricultural interests," and for this purpose they have complete freedom of intercommunication and can hold congresses. They are authorized to establish for their members mutual benefit societies and pension and relief funds, to open employment agencies, to give legal advice to, and in certain cases to bring actions on behalf of their members, and to organize the settlement of disputes by arbitration. They take part in the election of judges of the Tribunals of Commerce and of the Conseils de Prud'hommes, and may be requested by the courts to make statements as to trade and industrial customs and usages. They are competent to offer advice and address representations to the Government affecting the interests which they represent, and are not compelled, like other non-official associations and private individuals, to use stamped paper for the purpose.

Functions.

B. *State Departmental Organization.*

The State commercial departments and offices are chiefly centred round the Ministry of Commerce, to which is assigned the commercial part of the duties fulfilled in England by the Board of Trade. A Ministry of Commerce existed for short periods in 1811 and in 1828, but it was ultimately suppressed in 1829, and from that date until 1886, when the department received its present form and separate existence, commerce was only represented in the French Government by a subsidiary Bureau attached sometimes to one ministry, sometimes to another. The ministry is divided into three main Bureaus,—the first entrusted with all matters connected with the home trade and industry, the second with foreign and colonial relations, and the third with the compilation of statistics.

Ministry of Commerce.

Attached to the Ministry of Commerce is a body called the Conseil Supérieur du Commerce et de l'Industrie, which acts as an advisory council to the minister. Its origin goes back to the Council of Commerce established by Louis XIV., but it is now regulated by a decree of 1882. It is divided into two sections, a commercial and an industrial one, each composed of twenty-four members, who are nominated by the President of the Republic on the proposal of the Minister of Commerce. The members are selected from among senators, deputies, presidents of Chambers of Commerce and of Syndical Chambers, and men of recognized standing in the financial, industrial, and commercial worlds. The council only meets when summoned by the minister.

The Office National du Commerce Extérieur was established by a law of the 4th March 1898, and is carried on jointly by the Ministry of Commerce and the Chamber of Commerce of Paris, the latter having provided it with an installation at a cost of over 1,200,000 francs. The Office, which has been founded for the promotion of French trade with foreign countries and the dissemination of commercial intelligence, fulfils duties similar to those of the Commercial Intelligence Branch of the Board of Trade (p. 395). It also publishes the weekly *Moniteur Officiel du Commerce*. An ingenious system has been devised to secure for the Office the active co-operation of prominent French merchants residing abroad, by the creation of the title and functions of Councillor of Foreign Trade, which are conferred for a period of five years, by decree of the President of the Republic, upon a select number of such merchants, in return for their acting as information agents for the Office, and supplying regular reports upon the trade of the country in which they reside. The Office is governed by a council appointed partly by the Minister of Commerce and partly by the Chamber of Commerce of Paris, and its director and employés rank as civil servants.

National office for foreign trade.

The Office Colonial, whose duties are especially to furnish information concerning the French Colonies, to promote emigration thither, and to foster a demand in France for the produce of her Colonies, was established by a decree of the 14th March 1899. It is entrusted, in addition, with a permanent exhibition of colonial produce and a museum of samples of goods supplied by or required in the Colonies. The Office is also in charge of a colonial garden at Vincennes, where experiments are made for the acclimatization of colonial plants and produce in France, and the cultivation of French produce in the Colonies. The Office publishes a monthly bulletin of miscellaneous colonial information, and issues yearly commercial and other reports dealing with the Colonies. It is a dependency of the Ministry of the Colonies.

Office Colonial.

French consuls are instructed to transmit to their Government all information which they may consider useful for the prosperity of French trade and the development of French commercial influence abroad. It is also their duty to spread, in the country where

they reside, a knowledge of such French commercial and financial matters as they may consider most useful in the interests of their own country. The close relations which they are recommended to cultivate with the French commercial community within their jurisdiction through the local French Chamber of Commerce and the Councillors of Foreign Trade are intended to enable them to keep in better touch with commercial questions. They have had, however, to be frequently reminded of their commercial duties, and the French Chambers of Commerce have criticized them almost as much as the British Chambers have British consuls. The most important instructions issued to consuls were contained in circulars from the Minister for Foreign Affairs dated 15th March and 24th April 1883. French consuls have to make a return to their Government every fortnight—every month if the district is not of great commercial importance—showing, upon forms specially provided, the nature, quantity, origin, or destination, prices wholesale and retail, and chief trade marks of the goods imported into and exported from the district, the results of public sales of produce, the conditions of transport, contemplated public works and tenders advertised, state of the labour market, artistic enterprises, commercial failures and rumours concerning important local firms, effect of foreign competition, imitation of French trade marks, &c. These returns are mostly of a confidential nature, and are not intended for publication, but whenever the minister considers it advisable he causes information to be conveyed through the Chambers of Commerce, or other channels, to the parties chiefly interested. The ordinary Consular Reports are published in weekly instalments in the *Moniteur Officiel du Commerce*, which also contains selections from foreign consular reports and the reports of commercial students sent abroad by the high schools of commerce with travelling scholarships.

Consular service.

IV. Germany.

A. *Commercial Associations.*

German trade organizations are of three kinds, viz. :—

(*a*) Official organizations established by law, and called Handelskammern, or Chambers of Commerce;

(*b*) Semi-official associations; and

(*c*) Voluntary or "Free" associations.

(*a*) *Chambers of Commerce.*—Contrary to the idea prevalent in England, official trade-organizations in Germany are in a somewhat chaotic state. They have been established under more or less different conditions and systems in each State of the empire, and in certain districts still bear the imprint of foreign origin. They are under the control of the local State governments and lack the homogeneity and unity of direction of the French official system.

Before proceeding to a general examination of the German régime, special mention must be made of the Chambers of Commerce of the old Hanseatic Confederacy which stand apart, and whose duties, as well as constitution, differ from those of trade organizations in the rest of Germany. The Chambers of Commerce in Hamburg, Bremen, and Lubeck are not only the successors of, but (contrary to what happened in Germany as well as in other countries) have been evolved out of the old corporations which looked after the interests of the Hans traders in the olden days, and which, in the case of the Hamburg "Commerz-Deputation," for instance, dated as far back as 1665.

Hanseatic organizations.

The Hamburg Chamber of Commerce, whose present constitution dates from 1860, is composed of twenty-four members elected for six years by the ancient "Versammlung eines ehrbaren Kaufmannes," that is to say, the merchants and commercial men whose names appear on the register of the "Honest Merchants" of the city. Its income is chiefly derived from special taxation, to which are added the proceeds of the sale of contract and transfer stamps, and also the amount paid every year for the re-registration of each "Honest Merchant." This latter source of income amounts to about 70,000 marks per annum. The Chamber has to submit its accounts for approval to the Senate of the Republic.

In addition to the general duties of Chambers of Commerce in connexion with trade matters, the Hamburg Chamber—the same may also be said of the other Hanseatic Chambers—fulfils the combined functions of a Chamber of Shipping and of a Port and Docks Board. It appoints inspectors of shipping, of sailors, of rigging and machinery, and controls the administration of the sailors' fund. It has the right of proposing judges and of nominating experts attached to the courts. The exchanges and public sale rooms of the city are under its control, and it publishes the official quotations, as well as a weekly price list of goods and produce at the port of Hamburg. It is entitled to elect members to the "Bürgerschaft," or Lower House of Representatives, who are especially competent to deal with trade and shipping questions, customs duties, and emigration. The Chamber must be consulted by the "Bürgerschaft" with reference to all proposals affecting trade and navigation.

In Bremen, the Chamber is composed of twenty-four members elected by the "Ausschuss des Kaufmanns-Konvents," which comprises all the important commercial houses of the city. Two members go out every year, and no one can remain a member for more than eighteen years. The Bremen Chamber is intimately connected with the Senate of the Republic, a standing committee of both being in existence to settle questions affecting trade and navigation. In addition to the usual sources of income, the Bremen Chamber receives a subvention of 3500 marks from the town, and the salaries of its officials are fixed by law.

The Lübeck Chamber is composed of twenty members elected for six years by the associations representing the wholesale and retail trades. The president must be approved by the Senate, and is sworn in as a State official. He holds office for two years, and is not paid for his services, but when he goes out of office is presented with a sum of money subscribed by the townspeople. The Lübeck Chamber is probably the wealthiest organization of its kind in Germany, and is entrusted with the administration of the property of the old corporation of the "Vorstand der Kaufsmannschaft," which is very important. The Senate must consult it not only in trade and navigation matters, but also with reference to all contracts entered into on behalf of the State.

Chambers of Commerce in other parts of the German empire are not so important, nor are their duties so varied, as in the Hanseatic towns. The oldest ones were established by Napoleon in 1802 in Cologne, Crefeld, Aachen, Stolberg, and other towns which were then under the control of France, and they were submitted to the legislation which regulated the Chambers organized in France at the same time. The model set up by the French was more or less closely followed in the subsequent establishment of institutions of this nature in other German States. There were in 1902 eighty-eight Chambers of Commerce throughout the empire, the latest one established being, curiously enough, the Berlin Chamber, which was constituted on the 1st April 1902. A trade corporation called the "Aelteste der Kaufmannschaft" previously fulfilled, to a certain extent, the duties of a Chamber of Commerce. The new Chamber rests on a broader basis than the old corporation, which, however, remains intact, though the sphere of its action has been restricted.

Chambers of Commerce.

A detailed account of the system in force in every State of the German empire is hardly required here, and would not in any case present much interest, as the differences are mainly on points of detail. Broadly speaking, the German Chambers are elected by the registered tradespeople and merchants. In some States, *e.g.*, Bavaria, all the people on the Commercial Register have the right to vote; in others, *e.g.*, Baden, this right is limited to people living in the district, and paying a certain amount of taxes. The period for which members are elected is not uniform, but generally averages six years, one-half of the members going out every three years. Re-election is generally allowed. In Bavaria, there is a curious proviso that a person elected member of the Chamber of Commerce cannot refuse to serve, but can decline to be re-elected. Throughout the whole of Germany, Chambers are under the strict supervision of the State Minister of Commerce, and cannot be established except with his permission. He fixes the number of members as well as the amount of the State allocation to the Chamber. In Prussia and Bavaria, the Government is entitled to dissolve Chambers whenever it considers it advisable to do so, and there is always a Government commissioner in attendance at all meetings. In most cases, the local Government allows a fixed sum for the expenses of Chambers of Commerce, and if this amount is exceeded the electors who are on the Commercial Register have to make good the excess by the striking of a special rate. In some States, *e.g.*, Brunswick, Würtemberg, and Baden, the electors cannot be called upon to pay for deficiencies more than an amount fixed by law. In Bavaria, Chambers get a subvention from the district and central funds.

The duties and powers of the German Chambers are practically the same as those of the French Chambers, viz., to look after the interests of trade and industry in their respective districts, to administer stock and other exchanges, bourses, public sale rooms and warehouses, and commercial institutes, manage public

institutions founded for the promotion of commercial interests or commercial education, define and state rules and customs of trade, &c. In Prussia, they are, moreover, called upon to look after "the moral protection of clerks and apprentices."

The Prussian law of the 24th February 1870, amended by that of the 19th August 1897, regulates Chambers of Commerce and similar associations in Prussia. A Bill for the amendment of the law on the subject has been for some time under the consideration of the Reichstag, as the present system is very strongly criticized, and is in many quarters not considered satisfactory in view of modern trade requirements. The object of the promoters is to transform the Chambers into institutions of an imperial instead of a local character, and to enable them to be utilized more efficiently in promoting the general commercial interests of the empire.

The German Government did not, like the French, interfere with the liberty of association of Chambers of Commerce, and as a result German Chambers have united, together with other trade corporations, in an association called the "Deutsche Handelstag," which was founded in 1861, and has been carried on in its present form since 1886.

German Chambers abroad and foreign Chambers in Germany.

The German Government is understood to be opposed to the formation of German Chambers of Commerce abroad, and as a matter of fact there are no German Chambers in Europe outside of Germany. The writer is informed that a few have been established in South America, but that they are purely voluntary associations. No foreign Chambers of Commerce are known to exist in Germany. Steps were taken about 1898–1900 to bring about the creation of a British Chamber in Berlin, but they do not seem to have been successful.

(*b*) *Quasi-Official Corporations.*—Besides the Chambers of Commerce, there exist, chiefly in Prussia, various old-established and quasi-official corporations, whose views receive as careful consideration from the Government as do those of Chambers of Commerce. The Berliner Aelteste der Kaufmannschaft, previously mentioned, is one of the most important of these corporations, but the Gewerbekammer of Memel, the Kaufmännischen Verein of Breslau, the Vorsteher Amt der Kaufmannschaft of Koenigsberg, also deserve mention. Others exist in Elbing, Stettin, Danzig, Tilsit, and Magdeburg. They originated for the most part in ancient gilds or associations of commercial firms, and were organized in their present form between 1820 and 1825.

(*c*) *Voluntary Associations.*—Germany possesses also a large number of influential commercial associations of a voluntary character called the "Freie Vereine," which, especially in recent years, have greatly contributed to the commercial development of the Empire. One of the most important of these Freie Vereine is that of Düsseldorf. Similar ones also exist in Cologne, Kiel, Essen, Frankfort, &c. Some cover trade and industry in general, while others are limited to particular trades. They are all supported by the contributions of their members, and although they have no official standing, they are frequently consulted by both the imperial and local authorities.

B. *State Departmental Organization.*

The German empire has no Ministry of Commerce. As in the United States, commercial matters form only a department of the Ministry of State. Most of the States of the empire have, however, their own Ministries of Commerce, the oldest being the Prussian Ministry of Commerce and Industry, which dates from 1848.

Prussian Council of National Economy.

In Prussia, the Minister of Commerce is advised by the Volkswirthschaftsrath, or Council of National Economy, an official body constituted in 1880 by the Emperor William I. The functions of this council, which assembles periodically under the presidency of the Minister of Commerce, are almost similar to those fulfilled in France by the Conseil Supérieur du Commerce et de l'Industrie. It is composed of seventy-five members appointed for five years, of whom forty-five are selected from double that number of nominations submitted by Chambers of Commerce, mercantile corporations, trade associations, &c., the remaining thirty being appointed by the Government. It is divided into three sections—commercial, industrial, and agricultural, and its chief work consists in examining and advising as to bills and draft regulations affecting those interests brought forward in the name of the kingdom of Prussia in the Federal Council of the empire.

Commercial Museums.

Within recent years, the German Government has taken steps to facilitate the dissemination of commercial intelligence, by the establishment of Commercial Museums, which are variously called "Handelsmuseen," "Ausfuhrmusterlager," or "Exportmusterlager." The first of these, which are on the model of the Vienna Handelsmuseum, was opened in Berlin in 1883. Others followed in Munich, Karlsruhe, and Frankfort in 1884–85, in Cologne and Dresden in 1886–88, and later in Leipzig, Weimar, &c. They perform, to a certain extent, much the same functions as those performed in England by the Commercial Intelligence Branch of the Board of Trade, and the commercial and colonial departments of the Imperial Institute. They are centres of commercial information, and give advice to German manufacturers and merchants in their dealings with foreign countries. They keep samples of foreign manufactures which are competing successfully with German articles, as well as samples of goods suitable for export to certain countries. They examine and advise as to samples of raw materials and colonial produce, and endeavour to guide the German exporter in the direction in which his efforts are most likely to produce satisfactory results. The museums are free public institutions.

Consular service.

A perusal of the instructions given to German consuls with regard to commercial matters shows that the German consular body is in this respect very much in the same position as the British consular body. If German consuls as a whole have been especially active and successful in promoting German commercial interests, it is not on account of the nature of the instructions received from their Government, these instructions being to all intents and purposes similar to those issued to British consuls, but because particular care was taken to select consuls from a class of men imbued with the desire of increasing the greatness of their country by the promotion of German trade. Their action was prompted by their own personal feelings and business instincts and experience, and if it has been successful whilst remaining within the recognized bounds of consular work, it is because it was guided by an enlightened desire to place the general interests of the German empire before questions of personal convenience, or before the decorum of official inertia. The German consular body were not selected from a class of men trained from their early youth to look upon trade as below them, and to regard anything and anybody that "smells trade" as unworthy of their attention.

Agricultural attachés.

Of distinctly commercial attachés, like those of Great Britain and Russia, Germany has none; but in addition to the consular body, she is represented in foreign countries by five attachés or experts, whose duties are to study the movements of agricultural produce, and interest themselves in agricultural matters generally. They cover Great Britain, France, Russia, the Danube district, and the United States.

V. Belgium.

A. *Commercial Associations.*

The important place which Belgium has taken in international trade has directed much attention to her commercial organization, which comes nearer to the British model than that of any other European country. Belgian Chambers of Commerce were on the French system until 1875, when all official ties between them and the Government were broken, and full liberty was given to Commercial Associations to establish and govern themselves in their own way. The Belgian Chambers have now no administrative functions of any kind, but the Belgian Government never fails to consult them in matters likely to interest the commercial community. The most important Chambers are those of Antwerp, Brussels, Ghent, Liége, Charleroi, Verviers, and Namur. Mention should also be made of the Federations of Industrial and Commercial Associations at Antwerp and at Brussels, and of the Syndical Union of Brussels. In some places there are Liberal and Conservative Chambers of Commerce.

In addition to institutions representative of the general interests of commerce and industry, the principal trades have also in the larger cities separate associations or syndicates. The coal and iron trades are particularly strong in such associations, which are mostly located in Charleroi, Liége, and Namur. There are also a large number of associations for the promotion of colonial trade, which have grown up since the establishment of the Congo Free State. A number of Belgian Chambers of Commerce also exist abroad, the first of which was established in New York in 1867. Others have since come into existence, notably in London and Paris.

B. *State Departmental Organization.*

The Belgian Ministry of Commerce, under whose control commercial matters are placed, dates only from 1895, previous to which time the Department of Commerce at the Ministry for Foreign Affairs fulfilled the same functions. The Ministry has established in Brussels a Commercial Museum, similar to those of Germany and Austria, to centralize commercial intelligence and facilitate its dissemination. The Minister for Foreign Affairs, before appointing consuls, requests the advice of the most important Chambers of Commerce and trade associations, and submits for their consideration lists of candidates upon the relative merits of whom they are invited to express an opinion. The result is that the consular body is a remarkably capable one, and that, proportionately, it probably contains a smaller number of useless members than the consular body of any other nation. Attention to commercial duties is especially insisted upon, and in taking their oath of office Belgian

consuls promise that they will contribute, by every means in their power, to forward the interests of Belgian commerce and navigation. Explicit instructions are given to them not only to keep themselves well informed as to the commercial conditions of the country to which they are accredited, and to transmit this information for the use of the home trade, but also to give the greatest possible assistance towards securing an increase of the nation's export trade.

VI. Other Countries.

Austria-Hungary.—The control exercised by the Government over commercial organizations in Austria and in Hungary is very close. The only institutions of this kind of any importance within the dual monarchy are the Chambers of Commerce, of which there are twenty-nine. They are official bodies, regulated by the law of the 29th June 1868, which is, as regards the functions of Chambers, almost similar to the French law. But the Austrian Chambers, in certain cases, have the right to elect members of Parliament, which right depends upon taxation. A ministerial representative is entitled to attend all meetings, and to take part in discussions, but not to vote. The Minister of Commerce may dissolve a Chamber if it does not confine its activity within the prescribed limits, but a Chamber so dissolved must be reconstituted within three months. Chambers of Commerce are entrusted with the registration of trade marks and industrial designs. Within the Trieste district, one-third of the members of Chambers of Commerce may be foreigners.

Austria and Hungary have each a Ministry of Commerce, the former since 1853 and the latter since 1867, whose jurisdiction is strictly confined to internal trade matters in each country. Whenever important questions arise affecting common interests, the Gemeinsame Zoll-Conferenz, or Common Customs Conference, is summoned. This Conference is made up of representatives of the various ministries of both countries. Matters arising out of commercial relations with foreign countries are under the control of the Commercial Department of the Imperial Foreign Office.

The Vienna Commercial Museum was the prototype of similar institutions. It was established in 1875, as a consequence of the Vienna International Exhibition of 1873, and was followed shortly afterwards by the establishment of a similar one in Budapest. These museums are under the control of the respective Ministers of Commerce, and their object is to bring together producers and consumers, and to disseminate information in connexion with foreign markets. Special attention was, for some time, paid to collections of samples, but, as in the case of the Philadelphia Museum, this feature has not been found satisfactory.

Italy.—The Chambers of Commerce and Arts, which are regulated by the law of 1862, are official bodies. They are instituted, and may be dissolved by royal decree, and their functions are almost similar to those performed by the French Chambers. They are, however, at liberty to unite for the consideration of commercial and industrial questions of common interest, and are entitled to own property and to levy taxes for their maintenance. Contrary to the practice of other nations which have official Chambers of Commerce, the membership of Italian Chambers is not limited to subjects of the country. One-third of the elected members may be foreigners. The Italian Chambers are seventy-two in number. In addition to the Chambers of Commerce, there are in most towns of importance Chambers of Trade, which are local institutions.

An Advisory Council is attached to the Ministry of Commerce, which dates from 1878. This Council is called upon to give an opinion with reference to all matters connected with trade and industry. It is composed of eighteen members appointed by the king, of the representatives of eighteen Chambers of Commerce, of those of six other commercial corporations and of two working-men's associations, and of six *ex-officio* members belonging to various State Departments. There are also two commercial museums, one in Rome and one in Milan, the duties of which are similar to those performed by such associations in other European countries. Their expenses are paid by the Italian Government, under whose control they now are.

Spain.—Spanish Chambers of Commerce were organized by a royal decree of 1886, which places them under the control of the Ministro de Fomento. They are self-supporting bodies with unlimited membership, but have also an official standing. In order to belong to them one must be of Spanish nationality, be engaged in trade, have paid direct taxes to the State for at least five years for the business in connexion with which membership of the Chamber is sought, and pay annually the amount of the subscription provided by the regulations. The Government must consult Chambers of Commerce upon treaties of commerce and navigation, tariff changes, the creation of commercial exchanges and the organization of commercial education. The Spanish Chambers have played a prominent *rôle* during the last few years in connexion with the reform of the financial policy of the country and of taxation. The Madrid Chamber, especially, has taken a very pronounced line of action in these matters, which has not always been in accordance with the views of the Government. It must not be forgotten, however, that owing to the peculiarity of their constitution, the Spanish Chambers are much more representative of the feelings of the commercial community, and much less under the strict control of the Government, than similar institutions in other Continental countries. Spain has no Ministry of Commerce proper, the duties of this office being performed by the commercial sub-department of the Ministro de Fomento, which dates from 1847.

Portugal.—In Portugal, the organizations corresponding to Chambers of Commerce, which are called "Commercial Associations," are voluntary associations kept up by the subscriptions of their members. They have no official character, but cannot be established except by a royal decree approving their statutes, which approval can be withdrawn if they in any way depart from their object, or fail to send in annually their report to the Minister of Commerce, or to submit their accounts to him. These institutions, which are the only commercial associations of any kind in Portugal, are fifteen in number, including those in the adjacent islands and in the Colonies. The associations at Lisbon and Oporto are the only ones of importance.

The Portuguese Ministry of Commerce, which dates from 1852, is placed in contact with popular opinion on commercial and economic questions, by an institution called "The High Council of Commerce and Industry," which is composed of six members selected by the Government from persons whom it considers to be most competent to advise on matters connected with commerce and industry, three for each subject. The Minister of Commerce and two officials of his department are *ex-officio* members. The Government must consult this council with reference to customs and tariffs, railway rates, exhibitions, subsidies, banking, trade marks and patents, and labour in factories.

Russia.—Attached to the Department of Trade and Manufactures of the Ministry of Finance, which in Russia does duty for the Ministry of Commerce, there is an Official Council of Trade and Manufactures which sits in St Petersburg, and is presided over by a representative of the ministry. It consists of six honorary members, six *ex-officio* members, and twenty-four ordinary members, of whom fifteen are Russian officials and nine merchants of the first class or gild. The latter are almost all foreigners. Half the Council retire every two years, and the remaining half co-opt members to replace them. Nominations must be approved by the Minister of Finance and sanctioned by the Emperor. A similar Council of twenty-four members is also in existence at Moscow. In addition to these there are six local bodies, called the "Local Committees of Trade and Manufactures," entrusted with the care of commercial interests in Archangel, Odessa, Rostov-on-the-Don, Tver, Tikhvin, and Ivanovo-Voznesensk. At Warsaw, there is a "Committee of Manufactures" consisting of six members chosen by the Government from among the notables of the city and presided over by the Governor. The other "local committees" are elected as follows: the first and the second Gilds of Merchants elect by ballot a council of seventy members, and this council elects the twelve members who are to form the committee. All the committees are purely consultative bodies, but their opinion carries considerable weight, and although the Minister of Finance is perfectly free to reject it, he does not do so without good reasons. As will be gathered from the above, there is a difference between the St Petersburg and Moscow councils and the Warsaw committee on the one hand, and the local committees on the other. The former are official bodies, though merchants are represented on them, whilst the latter are almost Chambers of Commerce elected by the merchants among themselves.

Closer, however, to what we know as Chambers of Commerce are the institutions called "Exchange Committees." They are eighteen in number, one in each of the most important cities of the empire, and their importance has greatly increased of late years. They are voluntary associations, chosen by a council elected for the purpose by the commercial community, after the principle already explained in connexion with the Local Committees of Trade and Manufactures. They generally consist of twelve members elected for five years, and the president is appointed by the Minister of Finance. Foreigners are eligible. The Committee meets once a week at the local exchange, hence its name. The opinion of the Exchange Committees is frequently taken not only by the Minister of Finance, but also by other ministers, and they have always the right to petition the Minister of Finance if they wish to draw his attention to any matter. The Minister of Finance receives the president of the St Petersburg Exchange Committee in consultation every Saturday. Two important commercial societies, although unofficial, are recognized and frequently consulted by the Government, viz., the Society for the Encouragement of Russian Trade and Industry, of St Petersburg, and the Society for the Encouragement of Navigation, of Moscow.

The Russian Government is represented abroad by commercial

attachés, who are known as "agents of the Russian Ministry of Finance." The duties of these attachés, who are to be found in all the important capitals, are almost similar to those of the British commercial attachés, but they are entrusted with the promotion of Russian financial as well as commercial interests in the countries where they reside. There is also a Russian Chamber of Commerce in Paris.

Japan.—Commercial matters in Japan come within the cognizance of the Minister of State for Agriculture and Commerce. The chief commercial associations are the Chambers of Commerce, which are under the direct control of the Minister. Since the law of the 24th May 1902 they may be described as official bodies, with a constitution somewhat resembling that of the French Chambers. This law, which came into force on the 1st July 1902, provides that a Chamber shall consist of not more than fifty members, who must be Japanese subjects, elected by the commercial taxpayers of the town or district in which it is situated. Only Japanese commercial men, or companies and partnerships in which more than one-half of the directors or partners are Japanese, shall be entitled to vote. Permission to promote the establishment of a Chamber in a given district must be obtained from the Minister before any steps are taken, and the Chamber comes into existence only when the Minister has approved the steps taken by the promoters, and the proposed articles of association and bye-laws. The Minister has power to cancel anything done by a Chamber which seems to him detrimental to public interests, to dismiss officers or members, and if he thinks fit, to dissolve the Chamber. The expenditure of Chambers of Commerce is met by a special rate, which is paid by those entitled to vote for the election of members, and is fixed by the Minister or his representative, according to the requirements of each district. In addition to the usual consultative work of Chambers of Commerce, the Japanese Chambers may be authorized to build and manage commercial or industrial establishments. They also recommend judges and experts in commercial and industrial matters, and may be ordered by the Government to investigate commercial and industrial affairs. Chambers of Commerce which were in existence before the passing of the above law were given until 31st March 1903 to dissolve or reconstruct themselves in accordance with the new law. Since the exclusion of foreigners from the membership of Chambers of Commerce, foreign merchants resident in Japan have taken steps to establish foreign Chambers of Commerce, the chief of which are in Tôkyô and in Yokohama.

TRADE UNIONS.

I. THE UNITED KINGDOM.

THE present article is supplementary to the article TRADE UNIONS, on pp. 499–502 of vol. xxiii. of the ninth edition of this work, in conjunction with which it should be read, and to which reference should be made for a definition and general description of trade unions, and for an account of their legal position in Great Britain, and of the course of legislation concerning them. In the present, as in the former, article the term "trade union" is used mainly in its popular signification as an organization of workmen, for the purpose of improving the conditions of their employment, although legally the term is applicable also to associations of employers and to joint associations of employers and workmen.

So far as statute law is concerned, there has been no material change in the position of trade unions since the passage of the Trade Union Act of 1876, and for this part of the subject, therefore, the article in vol. xxiii. gives all the necessary information. The statement, however, at the end of the first paragraph, in small print (p. 500), with regard to registration, needs some qualification. The legal position of a registered trade union differs materially from that of a friendly or industrial and provident society. Thus, there is no legally enforceable contract between a trade union and its members binding it to pay the stipulated benefits and to carry out the rules, since no trade union can sue its members for contributions, or be sued by them for benefits; the right of a registered trade union to invest funds with the National Debt Commissioners is limited, and in certain other matters it does not enjoy the same privileges as a friendly society.

Since the legislation of 1876 there have been important decisions in the courts of law with reference to the provisions of the Conspiracy and Protection of Property Act, 1875, and the rights of trade combinations, for which see STRIKES AND LOCK-OUTS, *supra*, p. 19.

Important questions have also arisen as to the liability of individual officials of trade unions to civil actions for damages on account of recommendations they may have given to their members. The question has of course only been doubtful in case the action recommended is in itself lawful, but incidentally causes or is intended to cause the violation of some actionable private right. In the leading case on this point (*Allen* v. *Flood*) the delegate of the Boilermakers' Union informed an employer that the members of his society would give notice to leave work unless he ceased to employ two shipwrights who had given offence by working for a former employer on iron work. The employer therefore discharged the shipwrights, who brought an action against the boilermakers' delegate. The case was carried up to the House of Lords, whose final decision (14th December 1897) was in favour of the delegate, on the ground that his acts were in themselves lawful, and the action which they were intended to induce the employer to take was also lawful, and that such lawful acts would not constitute an actionable wrong to third parties who might incidentally be injured thereby.

But besides the liability of individual officials, it has

been decided in the House of Lords, in the case of the *Taff Vale Railway Co.* v. *The Amalgamated Society of Railway Servants* (1901, A.C. 426), that persons acting in concert, whether combined together in a trade union or collected and united under any other form of association, were as liable to be sued in respect of any damage occasioned to any other person through their act or default as any individual person might be liable. Consequently, the agents of a trade union who, in furtherance of a strike sanctioned and directed by its authorized officers, committed wrongful acts were held to have rendered responsible the principals who caused them to be committed; and it was further held that the trade union could be sued in its registered name, and would be liable for damages out of its common fund. Opinions were also expressed in the House of Lords that, whether registered or not, a trade union could be sued by its proper officers on behalf of themselves and the other members of the society, and that the judgment could be enforced against all funds forming the common fund of the society by adding the trustees if necessary.

Trade unions, in the sense in which the term is now understood, appear to be almost exclusively of modern growth. Though combinations among various classes of workmen to improve their position have doubtless been formed from time to time from an early period, such combinations, up to comparatively recent years, were mostly ephemeral, almost the only class among whom permanent associations of journeymen are known to have existed in the Middle Ages being the masons, whose confederacies were prohibited by law in 1425. With this doubtful exception, there is little or no trace of permanent combinations corresponding to the modern trade union before the 18th century. During the period when wages and conditions of employment were the subject of State regulation (*e.g.*, under the Statute of Apprentices of Elizabeth), combinations to exact higher rates or other conditions than those so fixed were naturally regarded as illegal conspiracies.

History.

The craft gilds of the Middle Ages have sometimes been regarded as the true predecessors of trade unions, but the analogy must not be pressed too far. The structure, constitution, and functions of a gild of craftsmen, aiming at the protection and regulation of the craft as a whole, were essentially different from those of a trade union, formed to protect one class of persons engaged in an industry against another. Nor is there any trace of direct continuity between gilds and trade unions, for the claim of certain Irish trade unions to be descended from gilds will not bear scrutiny (see Webb, *History of Trade Unionism*, Appendix). The only true sense in which it can be said that there is a certain indirect historical filiation between gilds and trade unions is that, as pointed out by Brentano, some of the earliest trade unions had for their original object the enforcement of the decaying Elizabethan legislation, which in its turn had taken the place of the obsolete regulation of industry by the craft gilds, so that among the rules and objects of such unions would naturally be some bearing a likeness to gild regulations.

The actual way in which trade unions first came into being probably varied very greatly. In some cases, as stated above, their origin can be definitely traced to associations for enforcing the legal regulation of industry against the opposition of employers; in others, the meetings of journeymen belonging to the same trade for such purposes as sick or burial clubs became naturally the nucleus of secret combinations to raise wages. The growth of the "capitalistic" system of industry, under which the workman no longer owned the materials or instruments with which he worked, was one of the most potent causes of the development of workmen's combinations. The efforts of trade unions to revive the enforcement of the Elizabethan legislation not only failed, but led to its repeal (1813–14); but the laws against combinations, which had been made more stringent and more general by the Acts of 1799–1800, remained unaltered until 1824 (vol. xxiii. p. 499). In spite of these Acts, which made all combinations illegal, there is evidence that trade clubs of journeymen existed and were tolerated in many trades and districts during the first quarter of the 19th century, though they were always subject to the fear of prosecution if they took hostile action against employers; and in many cases strikes were suppressed by the conviction of their leaders under these Acts or under the common law of conspiracy. The partial protection accorded to societies for the purpose of regulating wages and hours of labour by the law of 1825 (vol. xxiii. p. 500) led to a rapid multiplication and expansion of trade unions, and to an outburst of strikes, in which, however, partly owing to the widespread commercial depression, the workmen were mostly unsuccessful. Thus the first impetus given to trade unions by the modification of the combination laws was followed by a collapse, which in its turn was followed (in the third decade of the century) by a succession of attempts on the part of workmen to establish a federal or universal combination, to embrace members not of one but of several trades. To this new form of combination, which excited a good deal of alarm among employers, the term "trades union," as distinct from trade union, was applied. All these general movements, however, proved short-lived, and the last and most extensive of them, the "Grand National Consolidated Trades Union," which was formed in 1834 and claimed half a million adherents, only had an active existence for a few months, its break-up being hastened by the conviction and transportation of six Dorchester labourers for the administration of unlawful oaths. In the years of depressed trade which followed, trade unionism once more declined, and the interest of workmen was largely diverted from trade combinations to more general political movements, *e.g.*, Chartism, the Anti-Corn-Law agitation, and Robert Owen's schemes of co-operation.

From 1845 we trace another revival of trade unions, the characteristic tendency of this period being the amalgamation of local trade clubs to form societies, national in scope, but confined to single or kindred trades. High rates of contribution, and the provision of friendly as well as trade benefits, were among the features of the new type of union, of which the Amalgamated Society of Engineers, formed in 1851, was the most important example (see vol. xxiii. p. 501 for description of this society). The growth of unions of the new type was followed by a development of employers' associations in the 'sixties, and by a number of widespread strikes and lock-outs, and also by various efforts to promote arbitration and conciliation by the establishment of joint boards of employers and employed (see ARBITRATION AND CONCILIATION, and STRIKES AND LOCK-OUTS).

A series of outrages at Sheffield in 1865–66, in which officials of some local trade societies were implicated, led to the appointment in 1867 of a Royal Commission on Trade Unions, whose report was followed by the passage of the Trade Union Act of 1871, which as amended in 1876 now governs the legal position of trade unions (vol. xxiii. p. 500).

The period of inflated trade which began in 1871 led, as usual, to another rapid growth of trade combinations, of which the most characteristic feature was their extension to agricultural and general labourers. To meet this

new development of combination, the National Federation of Associated Employers of Labour was formed in 1873. The years of depression, 1875–80, were marked by a series of unsuccessful strikes against reductions of wages, and by a general decline of trade unions, which did not again revive until nearly ten years later, when the new wave of prosperous trade brought with it an outburst of strikes, chiefly among unskilled labourers, for improved conditions, of which the most notable was the strike of the London dock labourers in 1889. These trade movements were accompanied by the formation of a large number of unions of a type more akin to those of 1830–34 than to the more modern trade-friendly society with its high contributions and benefits. The "new unions" were chiefly among unskilled labourers; their rates of contributions were from 1d. to 3d. a week, and as a rule they only offered strike benefit. Another characteristic was the extent to which their leaders were permeated with the Socialistic doctrines which had then recently taken root in Great Britain, and which led them to advocate positive State interference with industry in the interests of the labourers (*e.g.*, the legal limitation of hours of labour).

The reports of the Royal Commission on Labour, which sat from 1891 to 1894, contain much valuable information on the state of facts and on the opinions of employers and workmen at this period.

From 1892 onwards the progress of trade unionism can be traced statistically (see below, p. 406). The depression of trade, 1892–95, brought with it, as usual, some decline in trade unionism; but though many of the "new unions" collapsed, some of the more important have survived to the present time. The revival of trade which began in 1896 has naturally been accompanied by an increase in the strength of trade unions; but the most marked characteristic of this period has been the extension and consolidation of employers' associations, of which perhaps the most notable is the Engineering Employers' Federation, which was originally formed on the Clyde, but gradually extended to other districts and became a national organization of great strength during its successful struggle with the Amalgamated Society of Engineers in 1897–98 (see STRIKES). Among the other more important employers' associations and federations of a national character may be mentioned the Shipping Federation, the Federated Coal Owners, the Federation of Master Cotton-Spinners' Associations, the National Federation of Building Trade Employers, and the Incorporated Federated Associations of Boot and Shoe Manufacturers.

Constitution.

The account given in the article on TRADE UNIONS in vol. xxiii. of the way in which the ordinary business of a trade union and its branches is conducted, applies fairly to the present state of things and need not be repeated here. As regards, however, the general structure and organization of trade unions, that article referred principally to a single important type of society, the national society, divided into districts and branches, of which the Amalgamated Society of Engineers served as an example. As a matter of fact, trade unions, both in their historical development and their present organization, present a very great variety of constitutions. The oldest type is that of the local trade club, consisting of a comparatively small number of men following the same occupation in the same locality. A large number of unions have never progressed beyond this primitive form of organization. The government is of the simplest kind, by a general assembly of all the members, while such officers as are required to carry on the necessary routine business of the society are chosen by rotation or even by lot.

Indisposition to concentrate power in the hands of permanent officers and a tendency to divide the business of management equally among all the members, instead of delegating authority to a few chosen representatives, are leading characteristics of trade unions in this primitive form. The organization here described, even if adequate for ordinary current requirements, is ill suited for conducting a contest with employers, and accordingly in times of strife an improvised "strike committee" often comes into existence and practically governs the conduct of the dispute. No doubt this double constitution of the old trade club as a loosely organized friendly society, converting itself from time to time into a more or less secret strike combination ruled by an irresponsible committee, is to be traced to the time when trade unions as such were illegal combinations and had to carry out their objects under the guise of friendly societies. The Friendly Society of Ironfounders (established in 1809), though it has to a great extent outgrown its primitive constitution, retains in its name the mark of its origin, while the government of the London Society of Compositors by mass meeting of its members offers an example of the persistence of traditional methods under wholly changed conditions. The Sheffield trade clubs, responsible for the outrages which led to the appointment of the Trade Union Commission in 1867, and subsequently to the passage of the Trade Union Acts, conformed as a rule to the primitive type. At the present time over 850 trade unions are known to exist which are purely local in character, with no branches. The next step in trade union evolution seems to have generally been an alliance or federation of two or more local clubs belonging to the same trade. This federation would make it necessary to provide some machinery for common management, the simplest and crudest expedient being for each of the allied clubs to act in rotation as the governing branch. Thus the government of the federation or "amalgamated society" was at any given time confided to the members of a single locality, and the seat of government was periodically shifted. Some federal societies (*e.g.*, the Mutual Association of Journeymen Coopers) still retain this primitive form of government.

As the tendency developed for local clubs to unite, the necessity of permanent officials to cope with the growing business of the amalgamation caused the institution of a paid secretary (usually elected by the whole body of members), and this led naturally to the fixing of the seat of administration at a particular centre instead of rotating among the branches. Some continuity of policy and of office tradition was thus made possible, but the executive committee almost invariably continued to consist of the local committee of the district where the seat of government happened to be. Thus up to 1892 the business of the Amalgamated Society of Engineers, a society with hundreds of branches all over the United Kingdom and even abroad, was conducted by a committee elected by the London branches.[1] The Boilermakers continued a somewhat similar form of government up to 1895; and many great societies, *e.g.*, the Amalgamated Society of Carpenters and Joiners, continue the system to the present day.

The plan of entrusting the government of a national society to a local executive has obvious conveniences, where the society consists of a body of working men scattered over a large area and with no leisure for travelling. But the control exercised by a locally-elected committee over a general secretary deriving his authority not from them but from the vote of a much wider

[1] This arrangement was in force when the article in vol. xxiii. was written.

constituency, could hardly be expected to be very effective; while the expedients of referring all important questions to a vote of the whole body of members, and of summoning at periodical intervals special delegate meetings to revise the rules, have proved in practice but clumsy substitutes for the permanent control and direction of the executive officers by a representative council. Quite as ineffective in some cases has been the authority of a mere local executive over the committees of other districts. Accordingly, some of the largest "amalgamated" unions have now adopted a representative system of government. Thus in 1892 the Engineers revised their rules so as to provide for the election of the executive council by vote of all the members divided into eight equal electoral districts. The members of council so elected are permanent paid officials, devoting all their time to the work of the society. The general secretary, however, continues to be chosen by the whole body of members, while the responsibility of the council is also weakened by the institution of "district delegates" nominally responsible to them, but chosen by direct election in the various districts. (This division of authority and consequent weakness of responsibility was one of the causes of the state of things which led to the great engineering dispute of 1897.) The Boilermakers adopted the system of a permanent executive in 1895.

In the case of certain highly-localized industries, such as cotton and coal, the conditions have admitted of a somewhat different form of constitution from that described above. Thus the Amalgamated Association of Operative Cotton-Spinners is a federal organization, consisting of a number of local associations, all, however, situated within a comparatively small area. The governing bodies of the association are—(1) a quarterly meeting of about a hundred representatives of the districts; (2) an executive committee of thirteen chosen by the above representative meeting, of whom seven must be working spinners and the other six are usually permanent district officials; (3) a sub-council to transact the ordinary daily work of the association, consisting of the six official members referred to above. The secretary is chosen by the representative meeting, and engages his own office assistants. Here we have the familiar features of representative institutions—a large legislative body, a small executive chosen by and responsible to this body, and a still smaller group of permanent officials to transact ordinary business.

Lastly, there are some large societies constituted not by the aggregation of local clubs or the federation of neighbouring associations, but originally founded as "national societies" divided into districts and branches for administrative convenience. An example is the Amalgamated Society of Railway Servants, founded in 1872.

Besides the tendency of the national society with branches to swallow up the local trade club, there is a further tendency among the larger societies to form federations for certain common purposes. Such federations are to be distinguished from national trade unions, inasmuch as their members are societies and not individuals, and as a rule their powers over their constituent organizations are limited to certain specific objects. On the other hand, they are more than merely consultative bodies (such as local trades councils).

Some federations consist of unions in the same industry in different districts (*e.g.*, the Miners' Federation). "Single trade" federations like this have usually considerable powers, including that of imposing levies.

In the cotton trade, the trade union organization has a federal character, and the Amalgamated Association of Operative Cotton-Spinners, in spite of its name, is strictly speaking a federation.

Other federations (*e.g.*, in the building trade) are formed of allied trades in the same locality, and usually have little executive power. The Federation of Engineering and Shipbuilding Trades has among its objects the settlement of disputes between members of its constituent societies as to the limits of their work. Some federations aim at embracing societies in all kinds of industries, but as a rule such organizations have not proved long-lived. The most recent example is the "General Federation of Trade Unions," formed in 1899, and now embracing 64 societies with nearly 400,000 members.

Since 1866, a congress of delegates from trade unions has met annually for discussion, and a parliamentary committee elected by this congress watches over matters in which trade unions are interested during the ensuing year.

Objects and methods.

The principal object of every trade union is to protect the trade interests of its members, and to strengthen their position in bargaining with their employers with regard to the conditions under which they work. The chief means by which they seek to attain these objects (apart from political methods such as the promotion of legislation or of administrative action by public authorities) are twofold: viz., the support of members when engaged in a collective dispute with employers by the payment of "dispute" benefit, and the insurance of members against loss from want of work by the payment of "unemployed" benefit, so as to enable them to refuse any terms of employment inferior to those recognized by the trade union. All trade unions in one form or another provide "dispute" benefit, but a separate "unemployed" benefit is by no means universal, though, except in certain groups of trades, it is usual among more powerful and well established societies. Thus in the mining, clothing, and even many branches of the building trade, comparatively little is spent by trade unions on "unemployed" benefit, while, on the other hand, in the metal, engineering, shipbuilding, printing, and other trades a large proportion of the total expenditure is devoted to this object (see *Statistics* below). In some important societies, such as the Amalgamated Society of Engineers, "unemployed" and "dispute" benefits are mixed up together, members engaged in a dispute receiving an addition of 5s. per week (known as "contingent" benefit) to the ordinary out of work pay (known as "donation").

Unemployed benefit may, of course, be regarded as a "friendly" benefit, *i.e.*, a provision against one class of the casualties to which a workman is exposed—the loss of employment through slackness of trade. But in practice it also operates as a method of maintaining the "standard" rate of wages, members being entitled to it who could obtain employment, but only on conditions disapproved by the society or branch.

The conditions under which the members of a union are entitled to financial support in a strike vary in different societies, and are prescribed in the rules. Usually, though the initiative may come from the localities, the central executive must approve of the strike before it takes place, and may at any time declare it to be closed, though in some societies the central authority is often unwilling to take the responsibility of curbing its members by exercising its powers in this respect.

"Dispute" and "unemployed" benefits are the only ones which are specially characteristic of trade unions, and as regards the latter benefit, it may be said that trade unions have hitherto been the only form of organization capable of meeting the difficulties arising from "malingering." Most of the more firmly established unions, however, add to their trade functions those of friendly societies,

providing sick, accident, superannuation, and funeral benefits, or some of these. The position of a trade union, however, with regard to these benefits differs very materially from that of a friendly society. As stated above, the society is under no legally enforceable contract with its members to provide the stipulated benefits: it can change their scale, or even abolish them, by vote of its members, and a member who has contributed for years in hope of receiving them has no legal redress. Again, a member excluded from the society for some "trade" reason incidentally loses all claim to friendly benefits. The funds of a trade union applicable to trade and friendly purposes are never kept distinct (in the few cases in which some distinction is attempted, the society may "borrow" from the one fund in aid of the other in case of emergency); and a prolonged strike or depression of trade may so deplete the funds as to make it impossible for the society to meet its engagements as regards sickness or superannuation. Thus the friendly society operations of trade unions have strictly no actuarial basis, and in some cases the scales of contribution and benefit have been fixed with little regard to ultimate solvency.

On the other hand, the power of levying and varying the scale of contributions adds to some extent to the financial stability of the funds, and the provision of "friendly" as well as "trade" benefits by a trade union undoubtedly gives strength and continuity to the society, and increases its power of discipline over its members. Societies that only provide "dispute" pay are exposed to violent oscillations of membership, and also to a dangerous temptation to rush into an ill-considered strike owing to the mere accumulation of funds which can be used for no other purpose.

The statistics of trade union expenditure on benefits of various classes are given below. Of the 100 principal unions, all provide dispute benefit; 78 in the year 1900 provided unemployed benefit (including in some cases travelling pay); 75, sick or accident benefit; 39, superannuation benefit; and 89, funeral benefit.

One of the most important functions of trade unions in many industries is the negotiation of agreements with employers and employers' associations for the regulation of the conditions of employment in those industries. While undoubtedly the power of withdrawing its members from employment in the last resort adds to the power of a trade union in such negotiations, many of the most important agreements by which the conditions of labour of large bodies of workmen are governed are habitually concluded, and from time to time revised, by conferences of representatives of the trade union and employers without any strike taking place. To the functions of trade unions as fighting organizations and as friendly benefit societies should therefore be added that of providing the necessary machinery and basis for the conclusion of industrial agreements between bodies of work-people and their employers (see ARBITRATION AND CONCILIATION, and STRIKES AND LOCK-OUTS).

While the broad objects of trade union policy are generally similar, their methods and features vary greatly in detail. Among the objects most frequently met with (besides those of raising wages and shortening hours, which may be said to be universal) are the enforcement of a "minimum" wage; the limitation of overtime; the restriction of numbers in the trade through the limitation of apprentices, or the regulation of the age of entrance; the restriction or regulation of piecework (in trades accustomed to "time" work); the preservation for members of the trade of the exclusive right to perform certain classes of work claimed by other trades (leading to so-called "demarcation" disputes); resistance to the encroachment of labourers on work considered to be "skilled" (leading to disputes as to the class of persons to be employed on machines, &c.); and the securing of a monopoly of employment for members of the union by a refusal to work with non-unionists.

Statistics.

The statistics of trade unions are very complete for recent years, but for earlier years the records are so fragmentary that it is impossible to give exact figures showing the total growth of trade unions over a long period. The following table, based on the statistics published by the Board of Trade, shows the number and membership of trade unions in the United Kingdom for each of the nine years 1892–1900:—

	Number of Unions.	Membership of Unions.[1]
1892	1208	1,502,358
1893	1255	1,479,417
1894	1295	1,436,300
1895	1311	1,407,836
1896	1317	1,494,465
1897	1307	1,613,998
1898	1267	1,648,732
1899	1302	1,800,869
1900	1272	1,905,116

[1] Includes a small number (9072 in 1900) of members abroad.

The fluctuations in membership correspond in the main to the oscillations of trade, membership declining in the years of depression following 1892, and increasing with the revival of trade which began about 1895. The later decline in the number of separate unions is chiefly due to the growing tendency to amalgamate into large societies.

The following table shows the distribution of trade unions among the various groups of trades in 1900:—

Groups of Trades.	Number of Unions.	Membership in 1900.	
		Number.	Percentage of Total.
Mining and quarrying	59	501,290	26
Metal, engineering, and shipbuilding	280	338,075	18
Building	131	253,822	13
Textile	237	220,685	12
Railway, dock, and other transport	66	171,219	9
Clothing	48	67,424	4
Printing and bookbinding	54	57,256	3
Wood-working and furnishing	123	39,704	2
General labour	19	113,209	6
Public employment	31	38,859	2
All other unions	224	103,573	5
Total	1272	1,905,116	100

This table shows that the strength of trade unionism lies in the four first-named groups of trades—mining, metal, engineering and shipbuilding, building and textile, which among them account for over two-thirds of the total membership.

In agriculture, trade unionism is at present practically non-existent, but in 1875 there were important unions of agricultural labourers, though at no time did they include any considerable proportion of the total agricultural population.

Taking the men belonging to all trade unions together, we find that their number does not amount to more than about one in five of the adult men who belong to the classes from which trade unionists are drawn. Only in a few groups do trade unionists form a high percentage of the total working population, *e.g.*, coal-mining and cotton manufacture. The number of women belonging to trade unions at the end of 1900 was 122,047, distributed among 138 unions, of which, however, only 27, with 8974 members, consisted exclusively of women. The great bulk (79 per cent.) of women trade unionists are found in the cotton trade, in which they actually outnumber the male members. Of all the women employed in factories and workshops, about one in twelve belongs to a trade union.

The available statistics with regard to the financial resources of trade unions, and their expenditure on various objects, are not so complete as those of membership, as the Board of Trade figures only relate to 100 of the principal unions. As, however, these unions include nearly two-thirds of the total membership, the

figures showing their financial position may be accepted as being representative of the whole number of societies. In 1900 the income of these 100 societies was £1,974,611, or 34s. 1d. per head; and their expenditure £1,490,582, or 25s. 8¾d. per head; and at the end of the year the funds in hand amounted to £3,766,625, or 65s. per head. Of the income, £1 10s. 11¼d. per head was derived from members' contributions, and 3s. 1¾d. per head from various other sources, *e.g.*, interest, fines, entrance fees, subscriptions, &c.

The above figures represent the average, but the actual rates of contribution vary greatly among the unions—from 7s. up to £4 per annum. Generally speaking, the highest income per member is found among the unions in the metal, engineering, and shipbuilding group, where in 1900 it averaged £3 1s. 3¼d., while the average in the mining unions was only £1 2s. 10¾d., and among dock labourers still lower. The metal trades and the textile unions appear to hold the highest amount of funds compared with their membership, the amounts at the end of 1900 being £5 0s. 6d. and £4 18s. 10½d. per head respectively in these groups, while in the clothing trade unions it was only £1 12s. 7d., and in some societies of unskilled labourers far less than this.

The main items of expenditure of trade unions are "dispute" benefit, "unemployed" benefit, various friendly benefits (including sick and accident, superannuation, and funeral), and working expenses. The proportions of expenditure on these various objects naturally vary greatly in different groups of unions, and also in different years, some of the items being affected largely by the general state of employment, and the occurrence or absence of important disputes. On the basis, however, of an average of the nine years 1892–1900, the following analysis of the proportionate expenditure of the 100 principal unions on various classes of objects has been made: on disputes, 20 per cent.; on unemployed, 22 per cent.; on friendly benefits (other than "unemployed"), 38 per cent.; on working expenses, 20 per cent. The 38 per cent. of expenditure on friendly benefits is made up of 17 per cent. on sick and accident, 10 per cent. on superannuation, and 11 per cent. on funeral and other benefits.

The mining unions devoted 40 per cent. of their expenditure to the support of disputes (friendly benefits in this industry being largely provided by other agencies), while the unions in the printing and bookbinding trades only used 6 per cent. for this object, over three-quarters of their expenditure going to unemployed or friendly benefits. As illustrations of the variation in the expenditure by the same group of unions on a particular object from year to year, it may be stated that within the nine years' period referred to the annual expenditure of the metal, engineering, and shipbuilding group on disputes varied from £12,633 in 1899 to £491,478 in 1897, the year of the great engineering dispute. Again, the expenditure of the same group of unions on unemployed benefit varied from £80,004 in 1899, a year of good trade, to £258,620 in 1894, a year of bad trade. The burden of superannuation payments by the 100 unions has steadily increased during the nine years from £102,578 in 1892 to £190,039 in 1900.

At the end of 1900 there were 110 federations, including societies with a gross membership of nearly a million and three-quarters; but a considerable deduction must be made from this total on account of duplication. In the same year 171 "Trades Councils" were known to exist, with an affiliated membership of about 754,000.

The number of employers' associations and federations known to exist in the United Kingdom at the end of 1900 was 870, including 47 federations and national associations. Of the total number of associations, nearly half are in the building trades.

II. Outside the United Kingdom.

Modern trade unionism has had its chief development in English-speaking countries, and especially in the United Kingdom, where the conditions necessary for its growth have been present to the fullest extent. With some exceptions, such unions as are found elsewhere are either derived or copied from English organizations, or are associations with political objects. It is therefore unnecessary to give more than a very brief summary of the position of trade unions in some of the principal countries and colonies outside the United Kingdom (for *United States* see p. 411).

Germany.—In Germany the majority of trade unions are of a political character, being closely connected with the Social Democratic party. These Socialist trade unions, termed "Gewerkschaften," were started by a congress held at Berlin in 1868, under the auspices of Fritscher and Schweitzer, two followers of Lassalle. In 1878 many of them were dissolved under the law prohibiting Socialistic organizations, but shortly after their place was taken by local unions termed "Fachvereine," which ostensibly abstained from politics, but which in various ways succeeded in evading the law and carrying on the work of the "Gewerkschaften." In 1887 a general committee of the German Gewerkschaften was formed. The last few years of prosperous trade have been marked by a rapid growth of membership of this group of unions. According to the *Correspondenzblatt*, their official organ, they included in 1899 a membership of 596,419, compared with 252,044 in 1894. Of the total members in 1899, 580,473 belonged to 7623 branches affiliated to 55 central federations, the membership of non-federated local unions being returned as only 15,946.

The total income of the federated trade unions in 1899 was £384,358, or about 13s. per member. The expenditure on trade purposes, including strikes, was £111,605, and on other benefits, unemployed, travelling, sick, &c., £74,245, the remaining expenditure being attributed to the publication of the journal, agitation, office, and miscellaneous expenses.

Another group of trade unions in Germany, less important as regards number and membership than the above, are the "Gewerkvereine," or non-political trade unions, sometimes known as "Hirsch–Duncker" unions, from the names of their founders. These unions were first formed in 1868, immediately after the Berlin congress referred to above. They were directly modelled on British trade unions. Since 1876 Social Democrats have been excluded. In their earlier years these unions suffered in membership from a series of unsuccessful strikes, and of late years they have been mostly benefit societies. At the end of 1899 the "Gewerkvereine" embraced 91,661 members belonging to about 1700 local unions affiliated to a central federation. Their expenditure on benefits amounted to less than £6000 a year, of which only about £600 was spent on disputes. The Christian trade unions ("Christliche Gewerkvereine") form another group, embracing, in 1899, 111,860 members in 36 trade unions, mainly in railway service, textile and mining industries.

As regards objects, methods, and organization, the National Printers' and Typefounders' Trade Union bears more resemblance to British trade unions than do any of the other German labour organizations. There seems to have been a long tradition of organization among journeymen in the German printing trade, going back to the 17th century. In 1848 the Gutenberg National Union of Printers was formed, but after an unsuccessful strike it broke up into local unions. The present union was formed in 1867, and became affiliated to the federation of "Gewerkschaften" in 1892. It has established a wages list, and secured other advantages for its members. It escaped the law of 1878 by changing its name. In 1899 its membership was 26,344, its income £79,000, and its funds amounted to £136,000.

It will be seen that German trade unions of one type or another include about 800,000 members. As regards, however, their direct influence on industrial conditions, they are not (with the exception of the printers' union) nearly so powerful as the British organizations.

France.—In France combinations of workmen as well as of employers were prohibited by the law of 1791, which overthrew the old gild or corporation system. They were also penalized under various articles of the Penal Code, and it was not till 1864 that the prohibition was modified by law. At present the status of trade unions in France is regulated by the law of 1884, which repealed that of 1791 and modified the articles of the

Penal Code so far as regards professional syndicates of employers or workmen. Since then there has been a considerable growth of workmen's unions, which in 1899 numbered 2685, with a membership of 492,647, compared with 2178 unions, with 403,440 members, five years previously. Of these unions, 1199 belonged in 1899 to 73 federations, of which the total affiliated membership is returned as 432,950, though there is here some duplication owing to the fact that some unions belong to more than one federation. The distribution of these unions among trades can only be stated for the year 1897, when out of a total membership of 437,793, 160,208 belonged to the group "transport and commerce," 41,760 to mining and quarrying, 38,316 to metal trades, 35,432 to textile industries, 33,795 to building trades, 27,967 to chemical trades, 20,262 to leather and skin trades (including boot, shoe, and glove trades), 18,552 to food-preparation trades, and the remainder to printing, furnishing, clothing, and other groups.

Austria-Hungary.—Apart from the Austrian gilds, membership of which is compulsory for persons engaged in non-factory handicrafts and trades (under a law of 1883) and in mining (under a law of 1896), there are a certain number of trade unions in Austria, though freedom of combined action among workmen is less complete than in many other European countries. Such right of combination as exists rests on the law of 1870, which removed the restrictions imposed by the Penal Code on combinations for influencing the conditions of labour. The impulse given to the formation of unions by this law, and by the advantages gained for the workmen during the years of prosperous trade that immediately followed, received a severe check during the succeeding depression of trade, when these advantages were mostly lost. Trade unionism did not revive until 1888, from which time the unions formed have mostly been on a Social Democratic basis, the majority being affiliated to a central organization in Vienna. In 1899, 409 trade unions and 604 "trade clubs" were known to be in existence in Austria. The latter class of associations are described as educational associations possessing to a greater or less extent trade union functions. The majority of trade clubs and a few trade unions are affiliated to a federation at Prague. Returns compiled by the committee of Austrian trade unions, and applicable to 391 trade unions and 492 trade clubs, showed a total membership of 157,773 persons in 1899 compared with 117,946 members in 313 trade unions and 527 trade clubs in 1896. Of the members in 1899, 128,504 belonged to trade unions in various groups of industries, of which the following are the principal in order of numerical importance: Metal trades, 18,374; transport (including railway service), 16,665; mining, 13,583; printing and allied trades, 12,750; glass and pottery, 9688; textile, 9470; clothing, 9083; building, 7790; wood-working, 7138.

The total receipts and expenditure of trade unions and clubs in respect of benefits other than dispute pay were, in 1899, £85,384 and £79,585 respectively. The expenditure on disputes was £14,977. The average annual expenditure per member of the organizations affiliated to the Vienna federation in 1899 was 11s. 4d., of which the amount spent on unemployed and travelling benefit was about 2s. 3d., on sickness 1s. 8½d., on superannuation 6¾d., on funerals 4d., on trade journals 1s. 7d., the remainder being accounted for by office and various miscellaneous expenses.

In Hungary trade unions are not far developed, the figures given on the authority of the Budapest Trades Council showing only 126 trade unions with 23,603 members in various industries, exclusive of unions of agricultural labourers, which it is stated brought up the membership to 64,000 in 1898–99.

Denmark.—In Denmark there were, in 1900, 1196 trade unions with 96,359 members—a very large membership compared with the total industrial population. The principal groups of trades represented were as follows in order of membership: General labourers, 29,044; building trades, 14,391; metal trades and shipbuilding, 10,954; transport, 8657; food, &c., trades, 7701; clothing, 6381; wood-working, 5520. Unemployed pay is said to be paid by 465 unions with 32,220 members, travelling benefit by 676 unions with 37,135 members, these being the most widely-spread benefits other than dispute pay. Over 80 per cent. of the members belong to unions affiliated to the General Federation of Danish Trade Unions. In 1896 unions with a membership of 63,377 had an income of £39,504 and an expenditure of £32,593.

Sweden and Norway.—In Sweden and Norway trade unions are of recent growth. There is a trade union membership of about 60,000 in Sweden, and of 24,000 in Norway. A National Federation of Swedish Unions was formed in 1898, and in 1900 was said to embrace 692 societies, with 39,132 members. In 1899 a federation was established in Norway.

Switzerland.—The only available statistics as to Swiss trade unions are the (avowedly incomplete) returns compiled by the Swiss "Arbeiter-Sekretariat," which show for 1899 a total of 758 local unions affiliated to 39 trade unions, with a membership of 49,034, of whom 17,451 belonged to unions affiliated to the General Federation of Swiss Trade Unions. Nearly a third of the total membership (16,066) is accounted for by seven trade unions of railway servants, the next largest group being Government employés (5655), followed by metal-workers (5373).

Holland.—In Holland in 1895 there were known to be 370 ordinary and 131 Roman Catholic trade unions, but little information is available as to membership or funds. Of the ordinary unions, 93 were in the building and kindred trades, 73 in food, drink, and tobacco trades, and 61 in transport industries. In 1893 a National Labour Sekretariat was formed, to which, in 1899, 45 societies with 13,050 members were said to be affiliated. The largest trade union in Holland was stated in 1900 to be the Diamond Workers' Federation, with 7000 members and an expenditure in 1899 of £12,260.

Belgium.—The status of trade unions in Belgium is regulated by the law of 1898, under which they can be incorporated, provided that their objects are non-political and are confined to the furtherance of the interests of particular trades. Belgian trade unions, nevertheless, are mostly political in character, the majority being connected either with the Socialist-Labour, Catholic, or Liberal parties. There are, however, a few unions (*e.g.*, the printers') independent of these parties. There are said to be altogether about 170 unions with from 60,000 to 70,000 members, of which about 100 unions are affiliated to the Labour party. In some trades (cigar-makers, wood-workers, printers, stoneworkers, painters, miners, and metal-workers) the unions have formed themselves into federations.

British Colonies.—Trade unionism has only developed to any important extent in a few of the industrial centres of the principal self-governing colonies. Unions in Canada are to a large extent branches of organizations having their headquarters in the United States or in England, and the purely Canadian unions do not present any features requiring special notice.

Between 1876 and 1890 all the principal Australian states passed statutes more or less resembling the Trade

Union Acts of the United Kingdom. A similar law was passed in New Zealand in 1878, but in this colony and in New South Wales trade unions can now become incorporated and acquire a special legal status by registering as industrial unions under the laws relating to industrial conciliation and arbitration. In the years immediately preceding 1890 certain Australian unions, especially among the shearers and the seamen and wharf-labourers, acquired great strength, and their determined attempts to secure a monopoly of employment for members of their organizations led to prolonged labour disputes in 1890 and 1891 (see STRIKES AND LOCK-OUTS, p. 27), which resulted in the defeat of the unions and a consequent diminution of their membership and influence.

AUTHORITIES.—For statistics of recent progress of trade unions, see annual reports on trade unions published by the Board of Trade (from 1887 onwards). Much information respecting trade unions is contained in the reports of the Royal Commission on Trade Unions (1867) and of the Royal Commission on Labour (1891–94). The reports of the Chief Registrar of Friendly Societies give information with regard to trade unions registered under the Trade Union Acts. On the history and constitution of trade unions the fullest information is given in WEBB's *History of Trade Unionism* and *Industrial Democracy*, both of which contain valuable bibliographical appendices which may be consulted as regards other sources of information respecting British trade unions. On trade unions abroad (besides the reports on foreign countries and the colonies of the Royal Commission on Labour), see KULEMANN'S *Die Gewerkschaftsbewegung* (Jena, 1900), dealing with trade unions in all countries, and the Board of Trade "Abstract of Foreign Labour Statistics" (1901) and *Labour Gazette*, both of which give numerous references to the foreign official sources of information on trade unions, together with a summary of the statistics which they contain.

III. ECONOMIC EFFECTS OF TRADE UNIONISM.

There is no general consensus of opinion as to the extent to which trade unions can attain success in achieving the objects which they set before themselves, or as to how far their action is beneficial or otherwise to the general community. One of the principal objects of trade unions being to maintain and increase the rates of wages paid to their members, the first question would be practically solved if statistical evidence were available to connect the course of wages with the action of combinations. Such evidence, however, is inconclusive. The period of growth of trade unionism in Great Britain has certainly been on the whole a period of rising wages. But many other causes tending to raise wages have been operative over the same period, and some of the facts might be explained as much by the tendency of rising wages to strengthen combinations as by that of combinations to raise wages.

Again, the observed fact that the rise has not been confined to industries in which organizations are strong might be explained either by the supposition that the rise brought about by trade unions has benefited a wider circle than their membership, or that the rise both within and outside the ranks of trade unions is due to causes other than their action. Perhaps the strongest statistical evidence of the power of trade unions to affect wages in particular districts is afforded by the local differences of wages in the same trade, which, it is contended, cannot be wholly explained by local differences of cost of living or industrial conditions, but which often correspond closely to differences of strength of trade union organization. This argument, however, does not touch the question of the effect of combination on the *general* level of wages.

Hardly more conclusive than the reasoning founded on statistics have been the attempts to solve the question by pure economic theory. During the prevalence of the old view of wages, known as the "wage-fund" theory, combinations were usually held to be powerless to affect the general rate of wages, because they could not alter the proportion between capital and population, on which wages were thought to depend. The question, however, was reopened by the change in theory which led economists to regard wages as depending primarily on the productivity of industry, and secondarily (and within comparatively narrow limits) on the relative power of bargaining as between the labourers or groups of labourers and the organizers of labour. According to this view, the effect of combinations on the rate of wages will ultimately depend, so far as the first and most important factor in the problem is concerned, on their effect on the general productiveness of industry. *Primâ facie*, we might expect that trade unionism would, on the whole, restrict productiveness, and this is undoubtedly a view widely held among employers. Strictly professional associations tend generally to become conservative so far as methods of work are concerned; and even trade unions which may not "officially" oppose the introduction of new processes and the use of machinery may nevertheless serve to focus and make effective the hostility felt by the artisan towards methods of business organization which seem to him likely to decrease the demand for his services or to alter the conditions of work to his detriment. In some trades also trade unions are charged with encouraging or permitting their members to restrict the amount of work performed by them in a given time, with the short-sighted object of making more work for others. Many unions have attempted also with varying degrees of success to keep up the value of their labour by creating an artificial scarcity by restricting the numbers entering the trade, and have in various ways sought to control the management of business to a degree which must restrict the freedom of experiment on which the attainment of the maximum productiveness of industry must depend. By the resort to strikes—an essentially wasteful method of settling differences with employers—they have also to some extent restricted production, though the loss directly due to this cause is often exaggerated (see STRIKES AND LOCK-OUTS). Moreover, by their insistence on the payment to all workmen of a fixed "minimum" wage they have diminished the field for the profitable employment of the old and less capable, and may to some extent have discouraged the expert workman from earning and receiving the full reward of his extra ability.

On the other hand, it is claimed that trade unions have in many cases acted in the interests of industrial peace by restraining their members from ill-considered strikes, and that, by providing a recognized channel through which the workmen's grievances may find expression, they have often assisted in adjusting differences which would otherwise have led to the interruption of production. It is also claimed that by protecting the "standard of life" of their members through the policy of securing a "minimum" rate of wages, trade unions may tend in the long run to build up a physically and industrially superior class of workmen, and thus ultimately increase the efficiency of industry.

The comparative weight of the above considerations differs somewhat according to the point of view from which the question is regarded. At any given time an individual employer may tend to feel most strongly the disadvantages of the restrictions under which he is placed by the action of a particular trade union, and may attach but little importance to the general effects, in the long run, on the national output of the pressure which such combinations exercise—which from the point of view of the general well-being of the community is the most important consideration. Generally speaking, any action of trade unions

tending to diminish the efficiency and industry of the individual workman is as injurious to the community as to the individual employer, except in so far as such restriction may conceivably affect the health of the working community from over-strain. But the policy of "levelling up" the standard rate of wages, which may mean loss or ruin to a particular employer, may nevertheless act quite otherwise with respect to the national well-being, in so far as it tends to eliminate the "unfit" employer and to concentrate the industry in the hands of the more capable and more enterprising of the employing class, and in the localities most suited for the purpose. The pressure of rising wages has undoubtedly acted as a stimulus to the invention of labour-saving devices and the adoption of economical methods, as is shown in America, where the highest wages are often seen concurrently with the lowest labour cost. Advocates of trade unionism sometimes lay much stress on this aspect of their operation. On the other hand, it must not be forgotten that competition, both as between different grades of employing ability and of local advantages, is now international, and that the concentration of an industry in the most suitable localities and in the hands of the most capable organizers, which is claimed as a beneficial result of trade union action, may for any particular country mean the transference of the industry abroad; and this transference, especially in the case of industries dependent on export to neutral markets, may involve a considerable national loss.

Apart from the effect of trade unions on the total amount of the "national dividend," their supporters claim that they are able to alter the mode of distribution of this dividend. It is not usually claimed that they are able to affect the proportion of the total product which is paid as rent or interest for the use of the instruments of production, but that they can alter the proportions in which the residue is shared between the organizers of labour and the manual labouring class, to the advantage of the latter. The methods by which trade unions seek to achieve this result require separate examination.

The first group of methods are those which aim at creating a scarcity of some particular kind of labour so as to alter the relation of demand and supply. The particular methods employed for this purpose have been already sufficiently described. With regard to all of them, it may be remarked that they are ineffective as regards the raising of the general rate of wages throughout the country (*i.e.*, the average income per head of the manual labour classes), seeing that an artificial scarcity of one sort of labour implies a redundancy of some other kind. As regards the rate of wages in particular occupations, there is no doubt but that at least for a time such methods may cause a considerable rise of wages, only limited at first by the imperfection of the control exercised by the union over the number competing in the labour market, and by the extent to which the rise in the cost of production so caused is checked by the competition of goods imported from abroad, or of alternative commodities, or by the loss of foreign markets, or the diminution of home demand. But as time goes on other forces of a more subtle kind tend to come into play which further limit the power of the combination to keep up wages through restricting the supply of labour. Besides the substitution of alternative commodities, alternative processes of production may be invented, diminishing the demand for the services of the members of the exclusive trade union, while the artificial rise of wages is also likely to attract labour into the trade.

Generally speaking, it may be said that while the artificial restriction of the supply of workmen in a trade may raise wages for a time, it calls into play forces tending to restore the equilibrium of demand and supply by diminishing demand, and that these forces grow progressively stronger as time goes on, while the restrictive capacity of the combination usually tends to diminish. This is apart from the fact that restriction of the supply of labour entering a trade almost always involves the narrowing of the field of ability from which the trade can be recruited, and thus a lowering of the general standard of efficiency.

The other group of trade union methods which requires examination is that which aims at strengthening the economic position of the labourer by substituting collective for individual negotiations as regards wages, supported by a common reserve fund out of which the labourer may be maintained while waiting for his terms to be accepted. Undoubtedly these methods of mutual insurance and collective bargaining afford a powerful instrument for preventing "sweating," and for enabling the whole body of workmen to exact at the earliest moment and retain to the latest moment the full amount of the wages which a given state of trade and prices will enable the industry to support. The establishment of general working rules and standards of time or piece wages throughout a trade or district may also serve to protect the better and more capable employers against their more inefficient or unscrupulous competitors, and thus tend towards the survival of the "fittest" among the employing class. It is always to be remembered that the effect of collective bargaining is not in the long run one-sided. Combinations of workmen beget counter-combinations of employers, and the conditions of important industries tend to be settled more and more by "treaties" concluded between powerful bodies of employers and employed. Were the combinations on both sides which enter into these agreements conterminous with the entire trades which they represent, and especially if the trades were protected from foreign competition, the interests of the general unorganized mass of consumers might conceivably suffer from these agreements. But as a general rule there has hitherto been sufficient outside competition, either within or without the country, to obviate this danger.

As regards the future prospects of trade unions in Great Britain, it is difficult to prophesy. The hopes of those who look for a universal expansion of these organizations so as to include the whole or the majority of the members of the manual-labour classes are certainly extravagant. Not less chimerical is the expectation of the opponents of trade unions that a few defeats at the hands of determined employers or employers' organizations will permanently cripple them and lead to their decay and extinction. Probably for many years trade unions will include, as now, in their membership a powerful minority of the working classes, wielding an influence out of all proportion to their actual numbers. It is to be expected that experience and the spread of education may cause them gradually to abandon the rules and methods which interfere most with the economical application of labour and capital to industry, while continuing to protect the interests of their members in the fair distribution of the joint product of industry.

Lastly, it may be pointed out that trade-unionism has been the result of the growth of a class of manual workmen working for wages for employers who provide the materials and instruments of industry, and into whose ranks it is relatively difficult for the average workman to rise. It is doubtful if the class feeling which enables trade unions to flourish can permanently be fostered and maintained except among workmen who expect to remain workmen most of their lives. If these conditions should be materially altered, trade unionism in its present form must decay or undergo a profound alteration. (X.)

IV. United States.

Trade unions in the United States are best treated from the broad standpoint of labour organizations generally, *i.e.*, associations of wage-earners having for their general purpose the improvement of their members, either through a lessened working day, increased wages, or more satisfactory rules and conditions of employment. They may or may not admit employers, but as a rule they do not admit them. Sometimes they are formed for a specific purpose, like the Eight-Hours League, but generally they have platforms comprehending all the demands which labour usually makes. Labour organizations in the United States cannot be given a definite birthday. Prior to 1825 there were very few of them. In colonial days we have hints of their existence, but their purpose was partly political, and their membership often consisted of politicians. The purpose of the Caulkers' Club, in the early days of Massachusetts, was "to lay plans for introducing certain persons into places of trust and power." Tradition has it that the word "caucus" was derived from this club. It is also said that Samuel Adams's father, as early as 1724, was active in the club's work. There was probably a union of journeymen bakers in the city of New York in 1741, and of shoemakers in Philadelphia in 1792. The shipwrights of New York City were incorporated 3rd April 1803, and the tailors and carpenters of that city were organized in 1806. The New York Typographical Society was in existence in 1817, and was probably organized in the early years of the 19th century. Peter Force was its president for a time, and Thurlow Weed was a member. A strike occurred in Mr Weed's office in 1821 on account of the employment of a non-union man, who was then designated a "rat." In 1823 was organized the Columbian Charitable Society of Shipwrights and Caulkers of Boston and Charleston.

Labour organizations.

The period from 1825 to 1860 may be called the formative period. About 1825, and for some years afterwards, there was a general discussion of Socialistic theories, growing out of Robert Owen's experiments at New Lanark, in Scotland, and out of his communistic attempt at New Harmony, Ind., in 1825. These experiments gave a great impetus to Fourierism, more than 200 communistic villages being founded, among them the celebrated Brook Farm, in Massachusetts. A large proportion of these experiments lasted only for a few years, but their influence has not yet ceased. The wave of transcendentalism also, which swept over the country between 1825 and 1840, affected not only social but industrial life. Labour papers began to be established. The *Working Man's Advocate*, published in New York City in 1825, was probably the very first American labour journal. Soon afterwards there appeared the *Daily Sentinel* and *Young America*, projected by two Englishmen, George Henry Evans and Frederick W. Evans. The chief demands advocated by these journals were the freedom of public lands, the breaking up of monopolies, the adoption of a general bankruptcy law, a lien for the labourer upon his work for his wages, the abolition of imprisonment for debt, equal rights for women with men, and the abolition of chattel and wage slavery. These demands were endorsed by over 600 newspapers. In 1830 a Working-man's Convention was held in Syracuse, N.Y., the outcome of which was the nomination of Ezekiel Williams for governor. In 1832 a delegated convention which met in the State House at Boston initiated the 10-hours movement. The *Tribune* (New York), under the leadership of Horace Greeley, was opened to the advocacy of Fourierism, and so on all hands the movement towards organization was helped. In 1845 the New England Working Man's Association was organized, and such men as Charles A. Dana, George Ripley, Albert Brisbane, Wendell Phillips, William Lloyd Garrison, Theodore Parker, and others participated in its meetings. The first industrial congress of the United States was convened in the city of New York, 12th October 1845, but little came of it. Other and more important labour congresses were held in that city and in Chicago in 1847 and 1850 respectively. During the latter part of the formative period, that is, from 1825 to 1860, most of the great national trades unions that are now influential were projected and organized, though their great and rapid growth has been since the Civil War. The National Typographical Union was organized in 1852, its name being changed to International in 1862 in order to admit Canadian members; the National Union of Hat Finishers in 1854; the Iron Moulders' Union of North America on 5th July 1859, and in the same year the Machinists' and Blacksmiths' Union of North America. By 1860 the national unions already formed numbered 26.

Formative period.

During the next few years, among other important organizations, were instituted what are known as the group of railway brotherhoods, the oldest and largest of which is the International Brotherhood of Locomotive Engineers. The grand division was founded at Detroit, Mich., 17th August 1863, under the name of the Brotherhood of the Footboard. The society was reorganized under its present title at Indianapolis, Ind., 17th August 1864. The second national association of railway employés that was organized was the Conductors' Brotherhood, formed at Mendota, Ill., 6th July 1868, by the conductors from various railways in the United States. This brotherhood was recognized, and a general governing board established, on 15th December of the same year. Ten years later the name of the organization was changed from the Conductors' Brotherhood to the Order of Railroad Conductors of America. The Brotherhood of Locomotive Firemen was organized at Port Jervis, N.Y., 1st December 1873. The Brotherhood of Railroad Trainmen was organized at Oneonta, N.Y., 23rd September 1883. It was called the Brotherhood of Railroad Brakemen until 1st January 1890, when the present name was adopted. The Brotherhood of Railroad Trackmen is one of the younger and smaller organizations. The first efforts to found it were made in the spring of 1887, but its permanent organization took place a year later. The Brotherhood of Railroad Carmen of America was founded 9th September 1890, by the consolidation of the Carmen's Mutual Aid Association, the Brotherhood of Railroad Car Repairers, the Car Inspectors, Repairers, and Oilers' Protective Association, and the Brotherhood of Railroad Carmen of Canada. The Switchmen's Union of North America is the outgrowth of the Switchmen's Mutual Aid Association, the present organization dating from 1897. At one time the Mutual Aid Association was a large and influential body. Several of these railway brotherhoods suffered materially in their membership and influence through the organization of the American Railroad Union in 1893.

Railway brotherhoods.

The Cigar-Makers' National Union dates from 1864, the Bricklayers' and Masons' International Union from 17th October 1865, the United States Wool Hat Finishers' Association from 1869, and the National Union of Horse-shoers of the United States from 1875. The Amalgamated Association of Iron and Steel Workers resulted, as its name signifies, from the consolidation of various other orders and societies, the present order being organized at Pittsburg in August

National unions.

1876. The consolidated societies were known previously to the new order of things as the United Sons of Vulcan, the Associated Brotherhood of Iron and Steel Heaters, Rollers, and Roughers of the United States, and the Iron and Steel Roll Hands' Union. The oldest of these bodies was the United Sons of Vulcan, originating in Pittsburg, 17th April 1858, and known as the Iron City Forge. The Granite Cutters' National Union was organized in 1877, the Brotherhood of Carpenters and Joiners in 1881, and the Journeymen Bakers' National Union in 1886. This ends the list of the leading trades unions of the United States. All are organized along what is known as trade union lines; each is devoted to its particular interests, and primarily has nothing to do with other unions. Many, such as the Cigar-Makers, the Carpenters, and others, have special publications relating to their particular work.

In sympathy each union is, of course, bound up with all unions, and there have been attempts to organize labour on a general or universal plan. The first of these was the International Association of Working-men, known as the "International," which was organized in London in the autumn of 1864. This society sought to associate working-men wherever manufacturing has been extended. The International grew for a while, but never at any time had a membership exceeding 100,000, and probably never over 50,000. It did not extend to the United States with much force; certainly no large number of the working-men of the country were involved in it, and branches were not organized in the Union until 1870 or 1871. The International took part in the Parisian difficulties in the latter year, and thus lost its influence with Americans; in fact, its experience there killed the society. Its programme and propaganda sowed some seeds, however, through its broad foundation. Its practices were generally condemned.

The International.

The second attempt was the Noble Order of Knights of Labour of America, which was founded in Philadelphia on Thanksgiving Day 1869, through the efforts of Uriah S. Stephens and six associates, all garment-cutters. For several years the garment-cutters of Philadelphia had been organized as a trade union, but failed to maintain satisfactory rates of wages. Dissatisfaction prevailed, and resulted in the autumn of 1869 in the disbandment of the union. Stephens, who was a far-seeing man, and anticipated the disruption of his union, had prepared the outlines of a plan for an organization embracing, as he said, "all branches of honourable toil." He advocated education, co-operation, and an intelligent use of the ballot as the proper means for gradually abolishing the present wage-system. The Order had a varied career. Mr Stephens, himself a Mason, brought into the ritual of the new Order many of the features of speculative Masonry. The obligations were in the nature of oaths, taken with much solemnity upon the Bible, and the members were sworn to the strictest secrecy. The Order was known for a long time as "Five Stars," that designation being used in printing and writing. Many expressions taken from Greek literature were introduced into the ceremonies. The instructions given to every person admitted into the order are perhaps the best exponent of the nature of the ritual:—

Knights of Labour.

> Labour is noble and holy. To defend it from degradation; to divest it of the evils to body, mind, and estate which ignorance and greed have imposed; to rescue the toiler from the grasp of the selfish—is a work worthy of the noblest and best of our race. In all the multifarious branches of trade, capital has its combinations; and, whether intended or not, they crush the manly hopes of labour, and trample poor humanity in the dust. We mean no conflict with legitimate enterprise, no antagonism to necessary capital, but men, in their haste and greed, blinded by self-interests, overlook the interests of others, and sometimes violate the rights of those they deem helpless. We mean to uphold the dignity of labour, to affirm the nobility of all who earn their bread by the sweat of their brows. We mean to create a healthy public opinion on the subject of labour (the only creator of values), and the justice of its receiving a full, just share of the values or capital it has created. We shall, with all our strength, support laws made to harmonize the interests of labour and capital, and also those laws which tend to lighten the exhaustiveness of toil. To pause in his toil, to devote to his own interests [*sic*], to gather a knowledge of the world's commerce, to unite, combine, and co-operate in the great army of peace and industry, to nourish and cherish, build and develop, the temple he lives in, is the highest and noblest duty of man to himself, to his fellow-men, and to his Creator.

The ritual was neither printed nor written, and in all probability there is not now in existence a copy of it. So long as the utmost secrecy was retained, the Order did not grow rapidly; gradually it lost its secrecy, and worked on more general plans. From the best evidence that can be secured, it is probable that the first Local Assembly of the Knights of Labour was organized as early as 1873, in Philadelphia. Attempts at outside organization had been unsuccessful. The second Assembly consisted of ship-carpenters and caulkers employed in Cramp's shipyard. After this the Order spread quite rapidly, 20 Assemblies being organized in Philadelphia during 1873. A District Assembly, consisting of delegates from Local Assemblies in Philadelphia, met in that city on Christmas Day 1873, and organized District Assembly No. 1. The Order increased during the years following this action, and in 1877 delegates were chosen to organize a General Assembly. These delegates met at Reading, Pa., 1st January 1878, and organized the first General Assembly, Mr Stephens, the founder, presiding as temporary chairman. Seven states were represented. General Assemblies have been held each year since that time, and changes in the constitution or work of the Order have been the subject of warm discussion. At the meeting of the first General Assembly the membership must have been small, probably only a few thousand. It did not reach 50,000 till five years later. The General Assembly of 1880, at Pittsburg, denounced strikes as injurious, and not worthy of support, except in extreme cases. At the fifth session, at Detroit, in 1881, the most important actions in the history of the Order were taken, and from this session the rapid growth of the Order may be dated. The Assembly then declared that on and after 1st January 1882 the name and objects of the Order should be made public. It also declared that women should be admitted upon an equal footing with men, and a strong committee was appointed to revise the constitution and the ritual. At the next General Assembly, September 1882, in New York, the revised constitution was adopted, as well as laws and regulations for supporting strikes. After this the Order began to grow rapidly. It antagonized the trade unions, the contention being that the Order embraced higher and grander principles than those underlying the organization of the former. The trade unions in existence at that time struggled to preserve their organizations against what they considered the encroachment of the Knights of Labour. The high-water mark of the Order was probably during 1883, 1884, 1885, and 1886, when, according to the very best information, it numbered not less than 1,000,000 members. In 1900 its membership was estimated at about 130,000.

The declaration of principles of the Knights of Labour calls attention to the alleged alarming development and aggressiveness of great capitalists and corporations, and makes the following specific claims or demands: To make industrial moral worth, not wealth, the true standard of individual and national greatness; to secure to the workers the full enjoyment of the wealth they create; sufficient leisure in which

Declaration of principles.

to develop their intellectual, moral, and social faculties, and all of the benefits, recreations, and pleasures of association. As means for securing these results, they demand at the hands of the State the establishment of Bureaus of Labour Statistics; that public land, the heritage of the people, be reserved for actual settlers; the abrogation of all laws that do not bear equally upon capital and labour; the adoption of measures providing for the health and safety of those engaged in mining, manufacturing, and building industries, and for indemnification for injuries received; the recognition by incorporation of trade unions, orders, and such other associations as may be organized by the working masses; the enactment of laws to compel corporations to pay their employés weekly, and giving mechanics and labourers a first lien upon the product of their labour to the full extent of their wages; the abolition of the contract system on national, state, and municipal works; the enactment of laws providing for arbitration between employers and employed; the prohibition by law of the employment of children under fifteen years of age in workshops, mines, and factories; that the hiring out of convict labour be prohibited, and that a graduated income tax be levied. They demand of Congress the establishment of a national monetary system, in which a circulating medium shall issue directly to the people; that interest-bearing bonds, bills of credit, or notes shall never be issued by the Government; the prohibition of the importation of foreign labour under contract; the organization of financial exchanges, safe deposits, &c., in connexion with the post office; the possession by Government, by purchase, of telegraphs, telephones, and railways. The Order pledges itself, while making the foregoing demands upon the state and national governments, to endeavour to establish a co-operative institution to supersede the wage system, to secure for both sexes equal pay for equal work, to shorten the hours of labour by a general refusal to work for more than eight hours, and to persuade employers to agree to arbitrate all differences which may arise.

Organization.

The Order of the Knights of Labour is based on the federal plan, and has a hierarchy of assemblies—the Local Assembly, the District Assembly, the State and the General Assembly. The officers of the Local Assembly consist of a Master Workman, Worthy Foreman, Venerable Sage, Recording Secretary, Financial Secretary, Treasurer, Worthy Inspector, Almoner, Statistician, and some minor officers. These are elected semi-annually by ballot or by acclamation. The District Assembly is composed of duly accredited delegates from at least five Local Assemblies, and is the highest tribunal of the Knights of Labour within its jurisdiction under the general laws of the Order. It has the power to levy assessments for its maintenance upon all Locals, and has also the power to establish Locals in the territory governed by it. The officers and their duties are similar to those of the Local Assembly, except that the Master Workman is called the District Master Workman. The constitution of the General Assembly is a very imposing document, containing twenty articles. The Assembly consists of representatives chosen by the District Assemblies, and has full and final jurisdiction, being the highest tribunal of the Order. It alone possesses the power and authority to make, amend, or repeal the fundamental and general laws of the Order, to decide finally all controversies arising, and to issue charters to State, District, and Local Assemblies. The officers are elected at each annual session, and their titles correspond almost completely with those of the Local and District Assemblies, with the exception that the word "General" takes the place of "District," as "General Master Workman," &c. The General Master Workmen have been Uriah S. Stephens (the founder of the Order), Terence V. Powderly, James R. Sovereign, John N. Parsons, and Henry A. Hicks, the present incumbent. The Order has a publication known as the *Journal of the Knights of Labour*, published at Washington, D.C.

American Railroad Union.

The third attempt to bring into one order men employed in different vocations was the American Railroad Union, organized in Chicago on 20th June 1893. It included all railway employés born of white parents. It was organized for the protection of members in all matters relating to wages and their rights as employés, and affirmed that such employés were entitled to a voice in fixing wages and in determining conditions of employment. The union won a great victory on the North-Western Railroad in April 1894, but its action in the great strikes in Chicago in 1894 cost it its life. Its membership reached at one time 150,000.

Federations of labour.

The separate unions found that the co-operation of other unions was needed to perfect and extend their work, and attempts were made from time to time to organize a federated body. The initial steps were taken in 1866, when the trades assemblies of New York City and Baltimore called a national labour congress, the 100 delegates sent by 60 secret and open organizations from different trades unions meeting on 20th August. In 1867 a second convention was called to meet in Chicago, the aim being to form a Trades Union Congress like that existing in Great Britain. The National Labour Union held two conventions in 1868, the first in May and the other in September; it met again in Chicago in 1869, in Boston in 1870, in Philadelphia in 1871, and in Columbus, O., in 1872. This closed the experience of the National Labour Union. During 1873, owing to the industrial depression, many of the trade unions were suspended. An Industrial Congress met in Rochester, N.Y., in April 1874, consisting of some of the leading trade unionists of the United States, and on the 14th of that month a convention was held representing the Sovereigns of Industry. The expectation was that the old National Labour Union should be taken up. The Industrial Brotherhood of the United States, another secret order, partaking largely of the character of the Knights of Labour, was represented in that convention. As might have been expected, the two ideas—that on which the Knights of Labour was organized, and the trade union idea—immediately became antagonistic, yet a platform containing most of the principles of the Knights of Labour was adopted. The movement ended with the Rochester meeting. The years 1875 and 1876 saw other attempts; but they were chiefly political in their character, and the temporary orders then organized were disbanded. Between 1876 and 1881 other attempts were made at federation. A call issued jointly by the Knights of Industry and a body known as the Amalgamated Labour Union, consisting of some dissatisfied members of the Knights of Labour, resulted in a convention held at Terre Haute, Ind., 2nd August 1881. The chief purpose was to supplant the Knights of Labour by the creation of a new secret order. The membership of the convention, however, had trade union proclivities, and did not believe in multiplying labour societies. The secret organization was not effected. Another convention was held in Pittsburg, 19th November 1881, as the result of the following statement:—

> We have numberless trades unions, trades assemblies or councils, Knights of Labour, and various other local, national, and international labour unions, all engaged in the noble task of elevating and improving the condition of the working classes. But great as has been the work done by these bodies, there is vastly more that can be done by a combination of all these organizations in a federation of trades and labour unions.

It is claimed that the 107 delegates represented 262,000 workmen. Their deliberations resulted in the Federation of Organized Trades and Labour Unions of the United States and Canada. Its platform differed but very little from that of the Knights of Labour, although it was in some respects more comprehensive. It demanded eight hours as a day's work; called for national and state incorporation of trade unions; favoured obligatory education of all children, and the prohibition of their employment under the age of fourteen; favoured the enactment of uniform apprentice laws; opposed bitterly all contract

convict labour and the truck system for payment of wages; demanded laws giving to working men a first lien on property upon which their labour had been expended; insisted upon the abrogation of all so-called conspiracy laws; advocated the establishment of a national bureau of labour statistics; urged the prohibition of the importation of foreign labour; opposed Government contracts on public work; favoured the adoption by states of an Employers' Liability Act; and urged all other labour bodies to vote only for labour legislators. The second convention was held at Cleveland, O., 21st November 1882. The Federation had many very difficult problems under discussion during the next few years, among others being the attempt to include Socialism and the doctrines of Anarchists; but the Federation has always stood out against these attempts, although at one time it seemed likely that it would become a Socialistic body, in full alliance with the Socialist Labour party.

The American Federation of Labour is the largest labour organization in the United States. It was organized at Columbus, O., 8th December 1886, under the name it now bears. In 1888 it was declared that it owed its existence to the Federation of Organized Trades, &c., founded in 1881 at Pittsburg, and that the American Federation meetings or conventions should date from that year; hence it is generally stated that the Federation was founded in 1881. From the start in 1881 the Federation had a constitution, but it revised it at the convention held in Baltimore, 16th December 1887, under the name of the American Federation of Labour. The order is not secret, nor do individual members, through local trades unions or otherwise, owe any allegiance to it. Its object is the encouragement and formation of local trades and labour unions, and the closer federation of such societies through the organization of central trades and labour unions in every State, and the combination of such bodies into state, territorial, or provincial organizations for the purpose of securing general harmony not only in the interests of the working masses, but of legislation. While it is a federation, it cannot be called a federal body, like the Knights of Labour, although there are local trade unions, trade assemblies in cities, and state federations; nevertheless, there is not the hierarchical character of the other body. Most of the trade unions in the United States are affiliated with the American Federation. The great railway brotherhoods are not so affiliated, except the Amalgamated Association of Railroad Employés of America, the Order of Railroad Telegraphers, and the Brotherhood of Railroad Trackmen.

Affiliated unions. The following is a list of the principal unions affiliated:— Actors' National Protective Union; Allied Metal Mechanics, International Union of; Bakers and Confectioners International, Journeymen; Barbers National, Journeymen; Blacksmiths, International Brotherhood of; Blast Furnace Workers and Smelters of America, International Association of; Boiler Makers and Iron Ship Builders, Brotherhood of; Bookbinders, International Brotherhood of; Boot and Shoe Workers' Union; Brewery Workers, National Union of United; Brickmakers' National Alliance; Bridge and Structural Ironworkers; Broom Makers, International; Carpenters and Joiners of America, United Brotherhood of; Carpenters and Joiners, Amalgamated Society of; Carriage and Wagon Makers, International; Wood Carvers' Association of North America, International; Cigar-Makers' International Union of America; Clerks' International Protective Association, Retail; Coopers' International Union of North America; Coremakers' International Union; Curtain Operatives of America, Amalgamated Lace; Drivers' International Union, Team; Electrical Workers of America, National Brotherhood of; Engineers, National Brotherhood of Coal Hoisting; Engineers, International Union of Steam; Engineers, Amalgamated Society of; Engravers, International Association of Watch Case; Firemen, International Brotherhood of Stationary; Fitters and Helpers, National Association of Steam and Hot Water; Garment Workers of America, United; Glass Bottle Blowers' Association of the United States and Canada; Glass Cutters' League of America, Window; Glass Flatteners' Association of North America, Window; Glass Workers' Union, American Flint; Gold Beaters' Union, National; Granite Cutters' National Union; Grinders' National Union, Table Knife; Hatters of North America, United; Horse Shoers of United States and Canada, International Union of; Hotel and Restaurant Employés' International Alliance and Bar-tenders' International League of America; Iron, Steel, and Tin Workers, Amalgamated Association of; Lathers, International Union of Wood, Wire, and Metal; Leather Workers on Horse Goods, United Brotherhood of; Longshoremen's Association, International; Machinists, International Association of; Meat Cutters and Butcher Workmen of North America, Amalgamated; Metal Polishers', Buffers', Platers', and Brass Workers' Union of North America; Metal Workers' International Association, Amalgamated Sheet; Mine Workers of America, United; Mine Workers' Progressive Union, Northern Mineral; Moulders' Union of North America, Iron; Musicians, American Federation of; Oil and Gas Well Workers, International Brotherhood of; Paper Makers of America, United Brotherhood of; Pattern Makers' League of North America; Plumbers, Gas Fitters, Steam Fitters, and Steam Fitters Helpers, United Association of; Plate Printers' Union of United States, National Steel and Copper; Printing Pressmen's Union, International; Potters, National Brotherhood of Operative; Railroad Employés of America, Amalgamated Association of; Railroad Telegraphers, Order of; Railroad Trackmen, Brotherhood of; Seamen's Union, International; Spinners' Association, Cotton Mule; Stage Employés' National Alliance, Theatrical; Stove Mounters, International; Tailors' Union of America, Journeymen; Textile Workers of America, National Union of; Tile Layers' Union, International Mosaic and Encaustic; Tin Plate Workers' International Protective Union of America; Tobacco Workers' International Union: Trunk and Bag Workers' International Union; Typographical Union, International; Weavers' Amalgamated Association, Elastic Web; Wood Workers' International Union of America, Amalgamated.

The state branches affiliated with it are those of Alabama, California, Connecticut, Florida, Georgia, Illinois, Iowa, Kentucky, Massachusetts, Michigan, Missouri, Nebraska, New York, New Jersey, North Carolina, Ohio, South Carolina, Texas, Utah, Virginia, and Wisconsin. The central labour unions, trades assemblies, or labour councils of cities are also affiliated with the American Federation. The chief officers of the Federation are a president, first, second, third, fourth, fifth, and sixth vice-presidents, treasurer and secretary. Samuel Gompers of New York was the first president, holding that position till 1894, when he was defeated through the endeavours of the Socialist Labour party, and John M'Bride elected. At the next session, however, he was re-elected, and has been the president ever since. The numerical strength of the American Federation of Labour is probably not far from 1,000,000. It maintains a journal called the *American Federationist*, published at Washington, D.C. The doctrine of the Federation relative to strikes is that each affiliated society has its own government, distinct from the government of the national convention, which has no power to order strikes, such matters being left to the affiliated societies, but is advisory, and not conclusive in its action.

Estimated strength. Unions are often organized for temporary purposes, their existence ceasing as soon as the purposes succeed or fail. The total number of members of all kinds of labour organizations cannot be stated. There are many local societies and associations other than those belonging to the Knights of Labour or those affiliated with the American Federation of Labour, but which are distinctly labour bodies. In 1900, according to the best possible classification, there were 18,000,000 wage-earners in the United States, including men, women, and children. The most liberal estimate of the membership of all labour organizations places the total at 1,600,000. This would be about 8 per cent. of the whole body of wage-workers; but in some occupations, like that of the printing trade, the organization probably includes from 75 to 90 per cent.; and so of other organizations of workers found very largely in the unions. It is not safe, therefore, to make calculations from general estimates.

In the state of New York in 1901 there were known to be 1881 trade unions with 276,141 members, of which 84,401 belonged to the building trades, 41,883 to the clothing trades, 17,896 to the printing and kindred trades,

35,562 to iron and steel trades, 34,371 to railway service, and the others to various other trades and industries. In Connecticut there were, in 1900, 340 trade unions, of which 122 returned a membership of 14,244. The greater part of the expenditure appears to have been on sick and funeral benefits and management.

The law relating to trade unions varies somewhat in the different states. Both the Federal Legislature and several of the states (Massachusetts, New York, Pennsylvania, Michigan, Maryland, Iowa, Kansas, and Louisiana) have passed laws permitting the incorporation of unions. Michigan, Wyoming, and Nebraska have specially provided for incorporating assemblies of the Knights of Labour. Hardly any advantage, however, has been taken of these statutes. Some states have passed laws excepting trade unions from restrictions on combinations and conspiracies imposed by other statutes or the common law (*e.g.*, New York), and especially from the operation of anti-trust laws (Michigan, Wisconsin, Nebraska, Montana, North Carolina, and Texas). The Texas law, however, has been held unconstitutional. A number of states have passed laws, some of doubtful validity, prohibiting employers from making it a condition of employment that labourers should not belong to a union. Most states have adopted statutes legalizing union labels to indicate the products of members of trade unions.

By Act of Congress, associations of the nature of labour organizations, having branches in several states or territories, may, on filing articles of association for record in Washington, become corporations. American legislation generally is friendly to trade unions. Their purposes are regarded as lawful by the courts, but if they use unlawful means for their accomplishments, a remedy will be applied. Injury to property, intimidation by threats, personal violence, or boycotts enforced by terrorism, are such unlawful means. The liberty of action thus secured to organizations of labour is equally the right of the employer. Therefore, a statute making it an offence for one to require those whom he employs to withdraw from a trade union is unconstitutional and void (see *Reports of American Bar Association*, volume xxi. 367, 372).

Traill, Henry Duff (1842–1900), English author and journalist, was born at Blackheath on 14th August 1842. When he left Oxford with the usual degree, he studied for the bar. He was called in 1868, but practised scarcely at all, and in 1871 obtained a post in the Education Office. This left him leisure to cultivate the literary gift which had clearly shown itself in him at Oxford, and in 1873 he became a contributor to the *Pall Mall Gazette*, then under the editorship of Mr Frederick Greenwood. He followed Mr Greenwood to the *St James's Gazette* when in 1880 the *Pall Mall Gazette* took for a time the Liberal side, and he continued to contribute to that paper up to 1895. In the meantime he had also joined the staff of the *Saturday Review*, to which he sent, amongst other writings, weekly verses upon subjects of the hour. Some of the best of these he republished in 1882 in a volume called *Recaptured Rhymes*, and others in a later collection of *Saturday Songs* (1890). He was also a leader-writer on the *Daily Telegraph*, and acted for a time as editor of the (Sunday) *Observer*. In 1897 he became first editor of *Literature*, when that weekly journal was established by the proprietors of *The Times*, and directed its fortunes until his death. But it was rather as a writer than an editor that Traill excelled. He wrote best when he wrote with least sense of the burden of responsibility. His playful humour and his ready wit were only given full scope when he was writing to please himself. One of his most brilliant *jeux d'esprit* was a pamphlet which was published without his name soon after he had begun to write for the newspapers. It was called *The Canaanitish Press and the Israelitish Question.* This told the story of the Exodus in articles which parodied very cleverly the style of all the leading journals of the day, and was at once recognized as the work of a born humorist. Traill sustained this reputation with *The New Lucian*, which appeared in 1884 (second edition with several new dialogues, 1900); but for the rest his labours were upon more serious lines. He directed the production of a vast work on *Social England* in 1893–98; he wrote, for several series of biographies, studies of Coleridge, Sterne, William III., Shaftesbury, Strafford, and Lord Salisbury; he compiled a biography of Sir John Franklin, the Arctic explorer; and after a visit to Egypt he published a volume on the country and another on Lord Cromer, the man who had done so much to bring it back to prosperity. Traill was certainly one of the most distinguished journalists of his day, and might well have left some enduring monument of his talent as a man of letters if he had not been so constantly occupied with ephemeral production. He died in London on 21st February 1900. (H. H. F.)

Tralee, a maritime town, market town, and urban sanitary district in the county of Kerry, Ireland, on the river Lee, 181½ miles W.S.W. of Dublin by rail. Large vessels discharge at Fenit, 8 miles westward, where a pier has been constructed, connected with the town by railway. In all 289 vessels of 1498 tons entered in 1900, and 120 of 23,459 tons cleared. Population about 9867.

Tranent, a police burgh of Haddingtonshire, Scotland, on the highroad between Edinburgh and Haddington, 9½ miles east of the former. The town thrives on the retail trade of its district and the surrounding coal-mines and quarries. It has the oldest coal-mining charter (1202–18) in Great Britain. A fragment of a parish church said to have been built in the 11th century is still standing. Tranent is being largely reconstructed. There is a town hall, an Elizabethan school, and a Roman Catholic boarding school. Population (1881), 2235; (1891), 2389; (1901), 2584.

Tranmere. See BIRKENHEAD.

Tranquebar, a town of British India, in the Tanjore district of Madras, on the sea coast, 22 miles north of Negapatam. Population (1891), 5000. It lost its importance when the railway was opened to Negapatam. The Lutheran mission high school (combined with one at the village of Shiyali on the railway) had 120 pupils in 1896–97. There is a mission press, issuing a monthly periodical in the vernacular, besides a reading room and literary institute.

Transbaikalia (*Zabaikalskaya Oblast*), a province of Eastern Siberia, to the east of Lake Baikal, bounded on the W. by Irkutsk, on the N. by Yakutsk, on the E. by the province of Amur, and on the S. by Mongolia. Its area is 236,868 square miles, and its population, which was 497,760 in 1882, numbered 664,071 (domiciled only)

in 1897, of whom 325,349 were women, and 36,823 lived in towns. The province is divided into five districts, the chief towns of which are Tchita (11,480 inhabitants), which is also the capital of the province, Barguzin (1378), Nerchinsk (6713), Selenghinsk (1076), and Verkhneudinsk (8002). Other towns are Kyakhta (4300), Nerchinskiy Zavod, and Sryetensk. The standard of education is low, there being less than 200 schools attended by less than 10,000 scholars. Mining, and especially gold mining, is important, but the production of gold has fallen off (4451 kilogrammes in 1882, 3882 kilogrammes in 1897). Silver mines have only a very small output (925 kilogrammes in 1897), and the production of iron is also insignificant (in 1897, 645 tons of pig iron and 532 tons of iron). Iron mining, however, is gradually developing, and explorations in connexion with the Trans-Siberian Railway have led to the discovery of good coal mines, which are now being worked. Salt is raised from several lakes to the amount of about 750 tons per annum, and the extraction of Epsom salts has considerably developed, nearly 1000 tons being obtained every year. Agriculture, however, continues to remain the main occupation of the people, and the average yield of all cereals is estimated to be not less than a million quarters yearly. Cattle-breeding is also of great importance, there being in the province over 500,000 horses and an aggregate of 2,700,000 head of various cattle. Hunting for sables and (especially) squirrels, and the gathering of nuts are widely followed. Manufactures, though insignificant, have somewhat increased. Transbaikalia is crossed by the Trans-Siberian Railway from Mysovaya on Lake Baikal, *viâ* Tchita, to Sryetensk, and from Kaidalovo, near Tchita, to the Mongolian frontier; this latter section is continued, as the main line, across Manchuria to Vladivostok and Port Arthur (see RUSSIA and SIBERIA). River navigation has been improved and extended; regular steamer communication has been established along Lake Baikal, not only for the transport of passengers and goods between the two railway stations of Listvenichnaya and Mysovaya, but also with the object of developing the fishing industry, which is of great importance. Steamers ply up the Selenga river as far as the town of Selenghinsk, considerable cargoes of tea being transported along this line. (P. A. K.)

Trans-Caspian Territory (*Zakaspiyskaya Oblast*), a province of Russia to the east of the Caspian Sea, bounded by Uralsk on the N., by Khiva and Bokhara on the N.E., by Afghan Turkestan on the S.E., and by the highlands of Afghanistan and Khorassan on the S. Its area is officially estimated at 220,540 square miles, but Strelbitzky reckons it to be only 214,240 square miles. In 1897 the domiciled population numbered 372,193, of whom 166,084 were women, and only 42,431 lived in towns; but, besides those of whom alone the census took account, there were about 25,000 strangers and troops. In 1895, when the population was estimated at 331,030, there were 240,200 Turcomans, 60,560 Kirghiz, 12,400 Russians (only 2174 peasants), 11,600 Persians and Tatars, 4170 Armenians, and 2100 of various nationalities. The province is divided into five districts, the chief towns of which are: Askhabad (19,428), which is also the capital of the province; Krasnovodsk (6359); Fort Alexandrovskiy (882), in the district of Manghishlak, on the Caspian Sea; Merv (8727), and Tejen (382). In 1898 there were only 24 schools with 1200 pupils.

The land is very rich in minerals: rock-salt covers over 80 acres on the island of Cheleken, and is also found at Bala Ishem, along the Uzboi, and in many lakes; while naphtha, ozokerite, and gypsum are found in several places. At the present time the chief minerals extracted are rock-salt, 18,300 tons in 1897; naphtha, 14,050 tons from Cheleken Island; gypsum, 1240 tons; sulphur, nearly 5000 tons. Nearly 300,000 acres are irrigated by the natives, and attempts are being made by the Government to increase the irrigated area by means of dams and new canals; it is considered that over 5,000,000 acres of land could be rendered suitable for agriculture. Strenuous efforts are being made to increase the forest area; several hundred thousand trees are planted every year, and a forest guard has been established to prevent useless destruction of the saksaul trees, which grow freely in the steppes. A model garden and a mulberry-tree plantation have been established at Askhabad in connexion with the gardening school. The land in the oases, especially those of the Atrek, is highly cultivated. In 1896, 1,300,000 cwt. of wheat and 220,000 cwt. of barley were grown, in addition to sorghum, Indian corn, rice, millet, and "kunjut" for oil. Raw cotton to the amount of nearly 3000 tons was obtained in 1896 in the Merv district, where nearly 10,000 acres were under this crop, and four factories were engaged in cotton cleaning. Gardening is well developed, and attempts are being made to encourage the spread of viticulture. Cattle-breeding is the chief occupation of the nomad Turcomans and Kirghiz. It was estimated in 1895 that there were in the province 106,000 horses, 44,000 horned cattle, 18,000 donkeys, 186,000 camels, and nearly 3,000,000 sheep and goats. Raw wool is exported to the value of 600,000 roubles per annum, as also over 60,000 hides and nearly 150,000 sheepskins. Considerable fishing is carried on off the coasts of the Caspian Sea, and seals are killed on the Manghishlak Peninsula. The natives follow a variety of domestic trades, in which they excel, chiefly the making of carpets, travelling bags, felt goods, and embroidered leather. The Russian population is chiefly limited to the military and the towns, only eight agricultural and three fishing villages containing Russians. Wheat, flour, wool, raw cotton, and dried fruit are exported, while tea, manufactured goods, timber, sugar, iron, paraffin oil are imported, as also rice and fruit from Bokhara, Turkestan, and Persia. The Trans-Caspian Railway, constructed across the province from Krasnovodsk to Merv, with a branch to Kushka, and from Merv to Bokhara and Russian Turkestan, has accomplished quite a revolution in the trade of Central Asia. The old caravan routes *viâ* Orenburg have lost their importance, and goods coming from India, Persia, Bokhara, and even China are now brought to different stations on the railway. The export of raw cotton from Bokhara along this line supplies the Russian cotton mills with a considerable portion of the raw material which they require, and in the year 1895 the exports of cotton, wool, dried fruit, hides, sheepskins, &c., were estimated at nearly 100,000 tons, while the imports of corn, metals, paraffin oil, and timber amounted to 613,000 tons. (For the recent history see RUSSIA: *History*.)

(P. A. K.)

Transformers.—An electrical transformer is the name given to any device for producing by means of one electric current another of a different character. The working of such an appliance is, of course, subject to the law of conservation of energy. The resulting current represents no more (in fact, always less) power than the applied current, the difference being represented by the power dissipated in the translating process. Hence an electrical transformer corresponds to a simple machine in mechanics, both transforming power from one form into another with a certain energy-dissipation depending upon frictional losses, or something equivalent to them. Electrical transformers may be divided into several classes, according to the nature of the transformation effected. The first division comprises those which change the form of the power, but keep the type of the current the same; the second, those that change the type of the current as well as the form of power. The power given up electrically to any circuit is measured by the product of the *effective value* of the current, the *effective value* of the difference of potential between the ends of the circuit, and a factor called the *power factor*. In dealing with periodic

currents, the effective value is that called the root-mean-square value (R.M.S.), that is to say, the square root of the mean of the squares of the time equidistant instantaneous values during one complete period (see ELECTRICITY: *Electric Current*). In the case of continuous currents, the power factor is unity, and the effective value of the current or voltage is the true mean value. As the electrical measure of a power is always a product involving current and voltage, we may transform the character of the power by increasing or diminishing the current with a corresponding decrease or increase of the voltage. A transformer which raises voltage is generally called a *step-up* transformer, and one which lowers voltage is called a *step-down* transformer.

Again, electric currents may be of various types, such as continuous, single-phase alternating, polyphase alternating, unidirectional but pulsating, &c. Accordingly, transformers may be distinguished in another way, in accordance with the type of transformation they effect. (1) *An alternating current transformer* is an appliance for creating an alternating current of any required magnitude and electromotive force from another of different value and electromotive force, but of the same frequency. An alternating current transformer may be constructed to transform either single-phase or polyphase currents. (2) *A continuous current transformer* is an appliance which effects a similar transformation for continuous currents, with the difference that some part of the machine must revolve, whereas in the alternating current transformer all parts of the machine are stationary; hence the former is generally called a rotatory transformer, and the latter a static transformer. (3) *A rotatory or rotary transformer* may consist of one machine, or of two separate machines, adapted for converting a single-phase alternating current into a polyphase current, or a polyphase current into a continuous current, or a continuous current into an alternating current. If the portions receiving and putting out power are separate machines, the combination is called a *motor-generator*. (4) A transformer adapted for converting a single-phase alternating current into a unidirectional but pulsatory current is called a *rectifier*, and is much used in connexion with arc lighting in alternating current supply stations. (5) *A phase transformer* is an arrangement of static transformers for producing a polyphase alternating current from a single-phase alternating current. Alternating current transformers may be furthermore divided into (*a*) single-phase, (*b*) polyphase. Transformers of the first class change an alternating current of single-phase to one of single-phase identical frequency, but different power; and transformers of the second class operate in a similar manner on polyphase currents. (6) The ordinary induction or spark coil may be called an intermittent current transformer, since it transforms an intermittent low-tension primary current into an intermittent or alternating high-tension current.

Alternating Current Transformer.—The typical alternating current transformer consists essentially of two insulated electric circuits wound on an iron core constituting the magnetic circuit. They may be divided into (1) open magnetic circuit static transformers, and (2) closed magnetic circuit static transformers, according as the iron core takes the form of a terminated bar or a closed ring. A closed circuit alternating current transformer consists of an iron core built up of thin sheets of iron or steel, insulated from one another, and wound over with two insulated conducting circuits, called the primary and secondary circuits. The core must be laminated or built up of thin sheets of iron to prevent local electric currents, called eddy currents, from being established in it, which would waste energy. In practical construction, the core is either a simple ring, round or rectangular, or a double rectangular ring, that is, a core whose section is like the figure 8. To prepare the core, thin sheets of iron or very mild steel, not thicker than ·014 of an inch, are stamped out of special iron (see ELECTROMAGNET) and carefully annealed.

Examples of the shapes in which these stampings are supplied are shown in Fig. 1. The plates when annealed are varnished or covered with thin paper on one side, and then piled up so as to make an iron core, being kept together by bolts and nuts or by

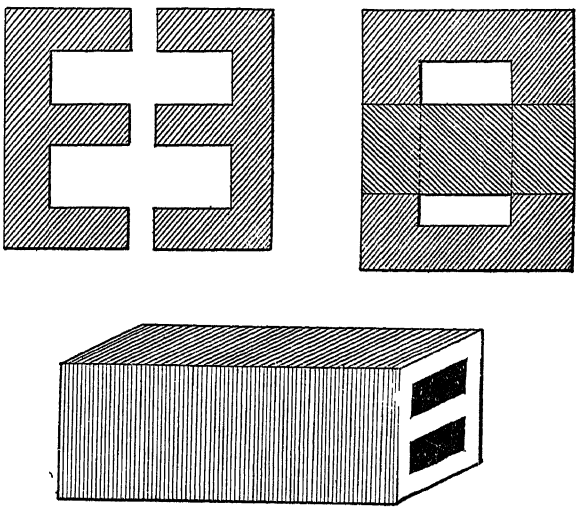

FIG. 1.—Transformer Stampings and Core.

pressure plates. The designer of a transformer core has in view, first, economy in metal, so that there may be no waste fragments, and second, a mode of construction that facilitates the winding of the wire circuits. These consist of coils of cotton-covered copper wire which are wound on formers and baked after being well saturated with shellac varnish. The primary and secondary circuits are sometimes formed of separate bobbins which are sandwiched in between each other; in other cases they are wound one over the other (Fig. 2). In any case the primary and secondary coils must be symmetrically distributed. If they were placed on opposite sides of the iron circuit, the result would be considerable magnetic leakage. Sometimes a metal shield is placed between the primary and secondary coils; in other cases safety sheets of mica or ebonite are used. The transformer is then well baked and placed in a cast-iron case sometimes filled in with heavy insulating oil, the ends of the primary and secondary circuits being brought out through water-tight glands. The most ordinary type of alternating current transformer is one intended to transform a small electric current produced by a large electromotive force (2000 to 10,000 volts) into a larger current of low electromotive force (100 to 200 volts). Such a transformer is called a step-down transformer, but it may be obviously employed in the reverse direction for raising pressure and reducing current, in which case it is called a step-up transformer. A transformer when manufactured has to be carefully tested to ascertain, first, its power of resisting breakdown, and, second, its energy-dissipating qualities. With the first object, the transformer is subjected to a series of pressure tests. If it is intended that the primary shall carry a current having an electromotive force of 2000 volts, an insulation test must be applied with double this voltage between the primary and the secondary, the primary and the case, and the primary and the core, to ascertain whether the insulation is sufficient. To prevent electric discharges from breaking down the machine in ordinary work, this extra pressure ought to be applied for at least a quarter of an hour. In some cases three or four times the working pressure is applied for one minute between the primary and secondary circuits. When such an alternating current transformer has an alternating current passed through its primary

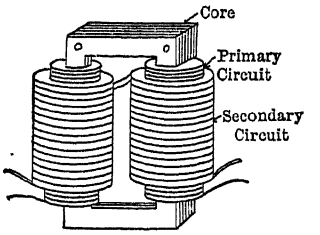

FIG. 2.—Closed Circuit Transformer.

circuit, an alternating magnetization is produced in the core, and this again induces an alternating secondary current. The secondary current has a greater or less electromotive force than the primary current according as the number of windings or turns on the secondary circuit is greater or less than those on the primary. Of the power thus imparted to the primary circuit one portion is dissipated by the heat generated in the primary and secondary circuits by the currents, and another portion by *the iron core losses* due to the energy wasted in the cyclical magnetization of the core; the latter are partly eddy current losses and partly hysteresis losses.

In open magnetic circuit transformers the core takes the form of a laminated iron bar or a bundle of iron wire. An ordinary induction coil is an instrument of this description. It has been shown, however, by careful experiments, that for alternating current transformation there are very few cases in which the closed magnetic circuit transformer has not an advantage. An immense number of designs of closed circuit transformer have been elaborated since

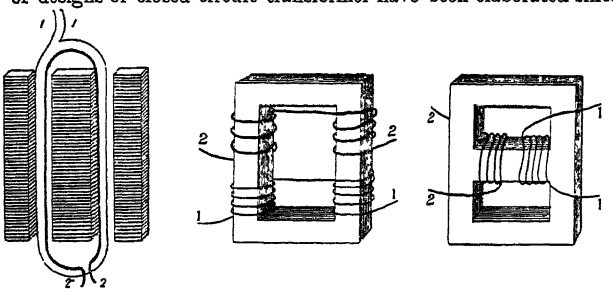

FIG. 3.—Diagrams of (A) Mordey (in section), (B) Kapp, and (C) Ganz Transformers.
1, 1, primary circuit; 2, 2, secondary circuit.

the year 1885. It suffices simply to mention the names of the principal modern types, such as those of Ferranti, Kapp, Mordey, Westinghouse, Berry, and Ganz. Diagrammatic representations of the arrangements of the core and circuits in some of these transformers are given in Fig. 3.

Alternating current transformers are classified into (i.) *Core* and (ii.) *Shell* transformers, depending upon the arrangements of the iron and copper circuits. If the copper circuits are wound on the outside of what is virtually an iron ring, the transformer is a core transformer; if the iron encloses the copper circuits, it is a shell transformer. Shell transformers have the disadvantage generally of poor ventilation for the copper circuits. Berry, however, has overcome this difficulty by making the iron circuit in the form of a number of bunches of rectangular frames which are set in radial fashion and the adjacent legs all embraced by the two copper circuits in the form of a pair of concentric cylinders. In this manner he secures good ventilation and a minimum expenditure in copper and iron, as well as the possibility of insulating the two copper circuits well from each other and from the core.

The ratio between the power given out by a transformer and the power taken up by it is called its *efficiency*, and is best represented by a curve, of which the ordinate is the efficiency expressed as a percentage, and the corresponding abscissæ represent the fractions of the full load as decimal fractions. The output of the transformer is generally reckoned in kilowatts, and the load is conveniently expressed in decimal fractions of the full load taken as unity. The efficiency on one-tenth of full load is generally a fairly good criterion of the economy of the transformer as a transforming agency. In large transformers the one-tenth load efficiency will reach 90 per cent. or more, and in small transformers 75 to 80 per cent. The general form of the efficiency curve for a closed circuit transformer is shown in Fig. 4. The horizontal distances represent fractions of full secondary load (represented by unity), and the vertical distances efficiency in percentages. The efficiency curve has a maximum value corresponding to that degree of load at which the copper losses in the transformer are equal to the iron losses.

Efficiency.

In the case of modern closed magnetic circuit transformers the copper losses are proportional to the square of the secondary current (I_2) or to qI_2^2, where q stands for the function $(R_1a^2+R_2)$; R_1 being the resistance of the primary and R_2 that of the secondary circuit, while a is the ratio of the number of secondary and primary windings of the transformer. Let C stand for the core loss, and V_2 for the secondary terminal potential difference (R.M.S. value). We can then write as an expression for the efficiency (η) of the transformer,

$$\eta=\frac{I_2V_2}{C+qI_2^2+I_2V_2}.$$

It is easy to show that if C_1, V_2, and q are constants, but I_2 is variable, the above expression for η has a maximum value when

$$C-qI_2^2=0,$$

that is, when the iron core loss C = the total copper losses qI_2^2.

Iron and copper losses.

The iron core energy-waste, due to the hysteresis and eddy currents, may be stated in watts, or expressed as a fraction of the full load secondary output. In small transformers of 1 to 3 kilowatts output it may amount to 2 or 3 per cent., and in large transformers of 10 to 50 kilowatts and upwards it should be 1 or less than 1 per cent. Thus the core loss of a 30-kilowatt transformer (one having a secondary output of 30,000 watts) should not exceed 300 watts. It has been shown that for the constant potential transformer the iron core loss is constant at all loads, but diminishes slightly as the core temperature rises. On the other hand, the copper losses due to the resistance of the copper circuits increase about 0·4 per cent. per degree Centigrade with rise of temperature. The current taken in at the primary side of the transformer, when the secondary circuit is unclosed, is called the *magnetizing current*, and the power then absorbed by the transformer is called the *open circuit loss* or magnetizing watts. The ratio of the terminal potential difference at the primary and secondary terminals is called the *transformation ratio* of the transformer. Every transformer is designed to give a certain transformation ratio, corresponding to some particular primary voltage. In some cases transformers are designed to transform, not potential difference, but current in a constant ratio. The product of the root-mean-square (R.M.S.), effective or virtual, values of the primary current, and the primary terminal potential difference, is called the *apparent power* or apparent watts given to the transformer. The true electrical power may be numerically equal to this product, but it is never greater, and is sometimes less. The ratio of the true power to the apparent power is called the *power factor* of the transformer. The power factor approaches unity in the case of a closed circuit transformer, which is loaded non-inductively on the secondary circuit to any considerable fraction of its full load, but in the case of an open circuit transformer the power factor is always much less than unity at all loads. Power factor curves show the variation of power factor with load. A low power factor always implies a magnetic circuit of large reluctance.

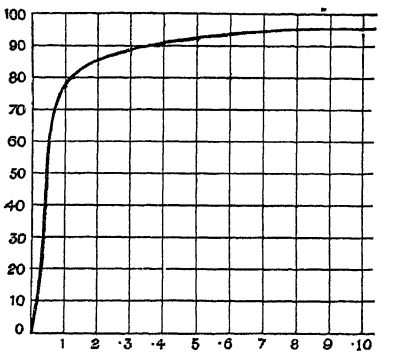

FIG. 4.—Efficiency Curve of Closed Circuit Transformer.

The operation of the alternating current is then as follows: The periodic magnetizing force of the primary circuit creates a periodic magnetic flux in the core, and this being linked with the primary circuit creates by its variation what is called the back electromotive force in the primary circuit. The variation of the particular portion of this periodic flux, linked with the secondary circuit, originates in this last a periodic electromotive force. The whole of the flux linked with the primary circuit is not interlinked with the secondary circuit. The difference is called the *magnetic leakage* of the transformer. This leakage is increased with the secondary output of the transformer and with any disposition of the primary and secondary coils which tends to separate them. The leakage exhibits itself by increasing the *secondary drop*. If a transformer is worked at a constant primary potential difference, the secondary terminal potential difference at no load or on open secondary circuit is greater than it is when the secondary is closed and the transformer giving its full output. The difference between these last two differences of potential is called the secondary drop. This secondary drop should not exceed 2 per cent. of the open secondary circuit potential difference.

Appraisement.

The facts required to be known about an alternating current transformer to appraise its value are (1) its full load secondary output or the numerical value of the power it is designed to transform, on the assumption that it will not rise in temperature more than about 60° C. above the atmosphere when in normal use; (2) the primary and secondary terminal voltages and currents, accompanied by a statement whether the transformer is intended for producing a constant secondary voltage or a constant secondary current; (3) the efficiency at various fractions on secondary load from one-tenth to full load taken at a stated frequency; (4) the power factor at one-tenth of full load and at full load; (5) the secondary drop between full load and no load; (6) the iron core loss, also the magnetizing current, at the normal frequency; (7) the total copper losses at full load and at one-tenth of full load; (8) the final temperature of the transformer after being left on open secondary circuit but normal primary potential for twenty-four hours, and at full load for three hours. The matters of most practical importance in connexion with an alternating current transformer are (1) the iron core loss, which affects the efficiency chiefly, and must be considered (*a*) as to its initial value, and (*b*) as affected by "ageing" or use; (2) the secondary drop or difference of secondary voltage between full and no load, primary voltage being constant, since this affects the service and power of the transformer to work in parallel with others; and (3) the temperature rise when in normal use, which affects the insulation and life of the transformer. The shellacked cotton, oil, and other materials with which the transformer circuits are insulated suffer a deterioration in insulating power if continuously maintained at any temperature much above 80° C. to 100° C. In taking the tests for core loss and drop, the temperature of the transformer should therefore be stated. The iron losses are reduced in value as temperature rises and the copper losses are increased. The former may be 10 to 15 per cent. less, and the latter 20 per cent. greater than when the transformer is cold. For the purpose of calculations we require to know the number of turns on the primary and secondary circuits, represented by N_1 and N_2; the resistances of the primary and secondary circuits, represented by R_1 and R_2; the volume (V) and and weight (M) of the iron core; and the mean length (L) and section (S) of the magnetic section. The hysteresis loss of the iron reckoned in watts per pound per 100 cycles of magnetization per second and at a maximum flux density of 2500 C.G.S. units should also be determined.

Testing.

The experimental examination of a transformer involves the measurement of the efficiency, the iron core loss, and the secondary drop; also certain tests as to insulation and heating, and finally an examination of the relative phase position and graphic form of the various periodic quantities, currents, and electromotive forces taking place in the transformer. The efficiency is best determined by the employment of a properly constructed wattmeter (see MEASURING INSTRUMENTS, ELECTRIC). The transformer T (Fig. 5) should be so arranged that, if a constant potential transformer, it is supplied with its normal working pressure at the primary side and with a load which can be varied, and which is obtained either by incandescent lamps, L, or resistances in the secondary circuit. A wattmeter, W, should be placed with its series coil, Se, in the primary circuit of the transformer, and its shunt coil, Sh, either across the primary mains in series, with a suitable non-inductive resistance, or connected to the secondary circuit of another transformer, T^1, called an *auxiliary transformer*, having its primary terminals connected to those of the transformer under test. In the latter case one or more incandescent lamps, L, may be connected in series with the shunt coil of the wattmeter so as to regulate the current passing through it. The current through the series coil of the wattmeter is then the same as the current through the primary circuit of the transformer under test, and the current through the shunt coil of the wattmeter is in step with, and proportional to, the primary voltage of the transformer. Hence the wattmeter reading is proportional to the mean power given up to the transformer. The wattmeter can be standardized and its scale reading interpreted by replacing the transformer under test by a non-inductive resistance or series of lamps, the power absorption of which is measured by the product of the amperes and volts supplied to it. In the secondary circuit of the transformer is placed another wattmeter of a similar kind, or, if the load on the secondary circuit is non-inductive, the secondary voltage and the secondary current can be measured with a proper alternating current ammeter, A_2, and voltmeter, V_2, and the product of these readings taken as a measure of the power given out by the transformer. The ratio of the powers, namely, that given out in the external secondary circuit and that taken in by the primary circuit, is the efficiency of the transformer.

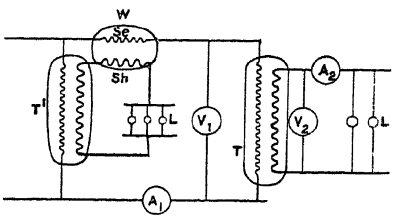

FIG. 5.—Arrangement for Testing Transformers.

In testing large transformers, when it is inconvenient to load up the secondary circuit to the full load, a close approximation to the power taken up at any assumed secondary load can be obtained by adding to the value of this secondary load, measured in watts, the iron core loss of the transformer, measured at no load, and the copper losses calculated from the measured copper resistances when the transformer is hot. Thus, if C is the iron core loss in watts, measured on open secondary circuit, that is to say, is the power given to the transformer at normal frequency and primary voltage, and if R_1 and R_2 are the primary and secondary circuit resistances when the transformer has the temperature it would have after running at full load for two or three hours, then the efficiency can be calculated as follows: Let O be the nominal value of the full

secondary output of the transformer in watts, V_1 and V_2 the terminal voltages on the primary and secondary side, N_1 and N_2 the number of turns, and A_1 and A_2 the currents for the two circuits; then O/V_2 is the full load secondary current measured in amperes, and N_2/N_1 multiplied by O/V_2 is to a sufficient approximation the value of the corresponding primary current. Hence O^2R_2/V_2^2 is the watts lost in the secondary circuit due to copper resistance, and $O^2R_1N_2^2/V_2^2N_1^2$ is the corresponding loss in the primary circuit. Hence the total power loss in the transformer $(=L)$ is such that

$$L = C + \frac{O^2}{V_2^2}R_2 + \left(\frac{N_2}{N_1}\right)^2\frac{O^2}{V_2^2}R_1$$
$$= C + (R_2 + R_1a^2)O^2/V_2^2.$$

Therefore the power given up to the transformer $O+L$ and the efficiency is the fraction $O/(O+L)$ expressed as a percentage. In this manner the efficiency can be determined with a considerable degree of accuracy in the case of large transformers without actually loading up the secondary circuit. The secondary drop, however, can only be measured by loading the transformer up to full load, and, while the primary voltage is kept constant, measuring the potential difference of the secondary terminals, and comparing it with the same difference when the transformer is not loaded.

Ageing.

No test of a transformer is complete which does not comprise some investigation of the "ageing" of the core. The slow changes which take place in the hysteretic quality of iron (see ELECTROMAGNET) when heated give rise to a time-increase in iron core loss. Hence a transformer which has a core loss, say, of 300 watts when new, may, unless the iron is well chosen, have its core loss increased from 50 to 300 per cent. by a few months' use. In some cases specifications for transformers include fines and deductions from price for any such increase; but there has in this respect been great improvement in the manufacture of iron for magnetic purposes, and makers are now able to obtain supplies of good magnetic iron or steel with non-ageing qualities. It is always desirable, however, that in the case of large sub-station transformers tests should be made at intervals to discover whether the core loss has increased by ageing. If so, it may mean a very considerable increase in the cost of magnetizing power. Consider the case of a 30-kilowatt transformer connected to the mains all the year round; the normal core loss of such a transformer should be about 300 watts, and therefore, since there are 8760 hours in the year, the total annual energy dissipated in the core should be 2628 kilowatt hours. Reckoning the value of this electric energy at only one penny per unit, the core loss costs £10 19s. 0d. per annum. If the core loss becomes doubled, it means an additional annual expenditure of nearly £11. Since the cost of such a transformer would not exceed £100, it follows that it would be economical to replace it by a new one rather than continue to work it at its enhanced core loss.

Iron sheet for transformer cores is always furnished to specifications which state the maximum hysteresis loss to be allowed in it in watts per pound (avoirdupois) at a frequency of 100, and at a maximum flux-density during the cycle of 2500 C.G.S. units. When plates having a thickness t are made up into a transformer core, the total energy loss in the core due to hysteresis and eddy current loss when worked at a frequency n and a maximum flux-density during the cycle B is given by the empirical formulæ

$$T = \cdot0032nB^{1\cdot55}10^{-7} + \left(\frac{tnB}{10^8}\right)^2$$

or

$$T^1 = 0\cdot88nB_1^{1\cdot55}10^{-9} + \frac{1\cdot4}{10^{10}}(t_1nB_1)^2,$$

where T stands for the loss per cubic centimetre, and T_1 for the same in watts per pound of iron core, B for the maximum flux-density in lines per square centimetre, and B_1 for the same in lines per square inch, t for the thickness of the plates in thousandths of an inch (mils), and t_1 for the same in inches. The hysteresis loss varies as some power near to 1·6 of the maximum flux-density during the cycle as shown by Steinmetz (see ELECTROMAGNET). Good sheet-iron for transformer cores should not have a hysteresis loss of more than 0·25 watt per pound per 100 cycles per 2500 B max.; it can be produced as low as 0·15 watt per pound, but with irons of very low hysteretic value there is always more risk of "ageing" than with the slightly higher values. The flux-density or induction in the core should never rise beyond a maximum value of 4000 to 5000, and it is preferably kept even lower. Since the hysteresis loss varies as the 1·6th power of the maximum flux-density during the cycle (B max.), the advantages of a low flux-density are evident. An excessively low flux-density increases, however, the cost of the core and the copper by increasing the size of the transformer. If the form factor (f) of the primary voltage curve is known, then the maximum value of the flux-density in the core can always be calculated from the formula

$$B = \frac{E_1}{4fnSN_1},$$

where E_1 is the R.M.S. value of the primary voltage, N_1 the primary turns, S the section of the core, and n the frequency.

Curve tracing.

The study of the processes taking place in the core and circuits of a transformer have been greatly facilitated in recent years by the improvements made in methods of observing and recording the variation of periodic currents and electromotive forces. The original method, due to Joubert, was greatly improved and employed by Ryan, Bell, Duncan and Hutchinson, Fleming, Hopkinson, and Rosa and Callendar; but the most important improvement was the introduction and invention of the oscillograph by Blondel, subsequently improved by Duddell (see description in MEASURING INSTRUMENTS, ELECTRIC). This instrument enables us, as it were, to look inside a transformer, for which it, in fact, performs the same function that a steam engine indicator does for the steam cylinder.[1] Delineating in this way the curves of primary and secondary current and primary and secondary electromotive forces, we get the following result:— Whatever may be the form of the curve of primary terminal potential difference, or primary voltage, that of the secondary voltage or terminal potential difference is an almost exact copy, but displaced 180° in phase. Hence the alternating current transformer reproduces on its secondary terminals all the variations of potential on the primary, but changed in scale. The curve of primary current when the transformer is on open secondary circuit is different in form and phase, lagging behind the primary voltage curve (Fig. 6); but if the transformer is loaded up on its secondary side, then the primary current curve comes more into step with the primary voltage curve. The secondary current curve, if the secondary load is non-inductive, is in step with the secondary voltage curve (Fig. 7). These transformer diagrams yield much information as to the nature of the operations proceeding in the transformer.

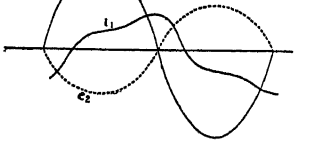

FIG. 6.—Transformer Curves at no load.

e_1, primary voltage curve; i_1, primary current curve; e_2, secondary voltage curve.

The form of the curve of primary current at no secondary load is a consequence of the hysteresis of the iron, combined with the fact that the form of the core flux-density curves of the transformer is always not far removed from a simple sine curve. If e_1 is at any moment the electromotive force, i_1 the current on the primary circuit, and b_1 is the flux-density in the core, then we have the fundamental relation $e_1 = R_1i_1 + SN_1db_1/dt$, where R_1 is the resistance of the primary, and N_1 the number of turns, and S is the cross-section of the core. In all modern closed circuit transformers the quantity R_1i_1 is very small compared with the quantity $SNdb/dt$ except at one instant during the phase, and in taking the integral of the above equation, viz., in finding the value of $\int e_1dt$, the integral of the first term on the right-hand side may be

[1] For a useful list of references to published papers on alternating current curve tracing see a paper by W. D. B. Duddell, read before the British Association, Toronto, 1897; also *Electrician* (1897), vol. xxxix. p. 636; also *Handbook for the Electrical Laboratory and Testing Room* (J. A. Fleming), vol. i. p. 407.

neglected in comparison with the second. Hence we have approximately $b_1 = \frac{1}{SN_1}\int e_1 dt$. In other words, the value of the flux-density in the core is obtained by integrating the area of the primary voltage curve. In so doing the integration must be started from the time point through which passes the ordinate bisecting the area of the primary voltage curve. When any curve is formed such that its ordinate y is the integral of the area of another curve, viz., $y=\int y^1 dx$, the first curve is always smoother and more regular in form than the second. Hence the process above described

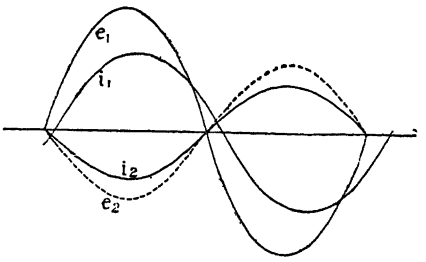

FIG. 7.—Transformer Curves at full load.

when applied to a complex periodic curve, which can by Fourier's theorem be resolved into a series of simple periodic curves, results in a relative reduction of the magnitude of the higher harmonics compared with the fundamental term, and hence a wiping out of the minor irregularities of the curve. In actual practice the curve of electromotive force of alternators can be quite sufficiently reproduced by employing three terms of the expansion, namely, the first three odd harmonics, and the resulting flux-density curve is always very nearly a simple sine curve.

We have then the following rules for predetermining the form of the current curve of the transformer at no load, assuming that the hysteresis curve (see ELECTROMAGNET) of the iron is given, set out in terms of flux-density and ampere-turns per centimetre, and also the form of the curve of primary electromotive force. Let the time base line be divided up into equal small elements. Through any selected point draw a line perpendicular to the base line. Bisect the area enclosed by the curve representing the half wave of primary electromotive force and the base line by another perpendicular. Integrate the area enclosed between the electromotive force curve and these two perpendicular lines and the base. Lastly, set up a length on the last perpendicular equal to the value of this area divided by the product of the cross-section of the core and the number of primary turns. The resulting value will be the core flux-density b at the phase instant corresponding. Look out on the hysteresis loop the same flux-density value, and corresponding to it will be found two values of the magnetizing force in ampere-turns per centimetre, one the value for increasing flux-density and one for decreasing. An inspection of the position of the point of time selected on the time line will at once show which of these to select. Divide that value of the ampere-turns per centimetre by the product of the values of the primary turns and the mean length of the magnetic circuit of the core of the transformer, and the result gives the value of the primary current of the transformer. This can be set up to scale on the perpendicular through the time instant selected. Hence, given the form of the primary electromotive force curve and that of the hysteresis loop of the iron, we can draw the curves representing the changes of flux-density in the core and that of the corresponding primary current, and thus predict the root-mean-square value of the magnetizing current of the transformer. It is therefore possible, when given the primary electromotive force curve and the hysteresis curve of the iron, to predetermine the curves depicting all the other variables of the transformer, provided that the magnetic leakage is negligible.

Elementary theory.

The elementary theory of the closed iron circuit transformer may be stated as follows:—Let N_1 N_2 be the turns on the primary and secondary circuits, R_1 and R_2 the resistances, S the section of the core, and b_1 and b_2 the co-instantaneous values of the flux-density just inside the primary and secondary windings. Then, if i_1 and i_2 and e_1 and e_2 are the primary and secondary currents and potential differences at the same instant, these quantities are connected by the two equations

$$e_1 = R_1 i_1 + SN_1 \frac{db_1}{dt},$$

$$e_2 = SN_2 \frac{db_2}{dt} - R_2 i_2.$$

Hence, if $b_1 = b_2$, and if $R_1 i_1$ is negligible in comparison with $SN_1 db/dt$, and $i_2 = o$, that is, if the secondary circuit is open, then $e_1/e_2 = N_1/N_2$, or the transformation ratio is simply the ratio of the windings. This, however, is not the case if b_1 and b_2 have not the same value; in other words, if there is magnetic leakage. If the magnetic leakage can be neglected, then the resultant magnetizing force, and therefore the iron core loss, is constant at all loads. Accordingly, the relation between the primary current (i_1), the secondary current (i_2), and the magnetizing current (i), or primary current at no load, is given by the equation $N_1 i_1 - N_2 i_2 = N_1 i$. Then, writing b for the instantaneous value of the flux-density in the core, everywhere supposed to be the same, we arrive easily at the identity

$$e_1 i_1 = e_2 i_2 + (R_1 i_1^2 + R_2 i^2) + S\frac{db}{dt}(N_1 i_1 - N_2 i_2).$$

This equation merely expresses the fact that the power put into the transformer at any instant is equal to the power given out on the secondary side together with the power dissipated by the copper losses and the constant iron core loss.

The efficiency of a transformer at any load is the ratio of the mean value, during the period, of the product $e_1 i_1$ to that of the product $e_2 i_2$. The efficiency of an alternating current transformer is a function of the form of the primary electromotive force curve. Experiment has shown[1] that if a transformer is tested for efficiency on various alternators having electromotive force curves of different forms, the efficiency values found at the same secondary load are not identical, those being highest which belong to the alternator with the most peaked curve of electromotive force, that is, the curve having the largest *form factor*. This is a consequence of the fact that the hysteresis loss in the iron depends upon the manner in which the magnetization (or what here comes to the same thing, the flux-density in the core) is allowed to change. If the primary electromotive force curve has the form of a high peak, or runs up suddenly to a large maximum value, the flux-density curve will be more square-shouldered than when the voltage curve has a lower form factor. The hysteresis loss in the iron is less when the magnetization changes its sign somewhat suddenly than when it does so more gradually. In other words, a diminution in the form factor of the core flux-density curve implies a diminished hysteresis loss. The variation in core loss in transformers when tested on various forms of commercial alternator may amount to as much as 10 per cent. Hence, in recording the results of efficiency tests of alternating current transformers, it is always necessary to specify the form of the curve of primary electromotive force. The power factor of the transformer, or ratio of the true power absorption at no load, to the product of the R.M.S. values of the primary current and voltage, and also the secondary drop of the transformer, vary with the form factor of the primary voltage curve, being also both increased by increasing the form factor. Hence there is a slight advantage in working alternating current transformers off an alternator giving a rather peaked or high maximum value electromotive force curve. This, however, is disadvantageous in other ways, as it puts a greater strain upon the insulation of the transformer and cables. At one time a controversy arose as to the relative merits of closed and open magnetic circuit transformers. It was, however, shown by tests made by Fleming and by Ayrton on Swinburne's "Hedgehog" transformers, having a straight core of iron wires bristling out at each end, that for equal secondary outputs, as regards efficiency, open as compared with closed magnetic circuit transformers had no advantage, whilst, owing to the smaller power factor and consequent large R.M.S. value of the magnetizing current, the former type had many disadvantages (see Fleming, "Experimental Researches on Alternate Current Transformers," *Proc. Inst. Elec. Eng.*, 1892).

Magnetic leakage.

The discussion of the theory of the transformer is not quite so simple when magnetic leakage is taken into account. In all cases a certain proportion of the magnetic flux linked with the primary circuit is not linked with the secondary circuit, and the difference is called the magnetic leakage. This magnetic leakage constitutes a wasted flux which is non-effective in producing secondary electromotive force. It increases with the secondary current, and can be delineated by a curve on the transformer diagram in the following manner. The curves of primary and secondary electromotive force, or terminal potential difference and current, are determined experimentally, and then two curves are plotted on the same diagram which represent the variation of $(e_1 - R_1 i_1)/N_1$ and $(e_2 + R_2 i_2)/N_2$; these will represent the time differentials of the total magnetic fluxes Sb_1 and Sb_2 linked respectively with the primary and secondary circuits. The above curves are then progressively integrated, starting from the time point through which passes the ordinate bisecting the area of each half wave, and the resulting curves plotted to express by their ordinates Sb_1 and Sb_2. A curve is then plotted whose ordinates

[1] See Dr G. Roessler, *Electrician*, vol. xxxvi. p. 150 (1895); Beeton, Taylor, and Barr, *Journal Inst. Elec. Eng.*, vol. xxv. p. 474; also J. A. Fleming, *Electrician*, vol. xxxiii. p. 580 (1894).

are the differences $Sb_1 - Sb_2$, and this is the curve of magnetic leakage.

The existence of magnetic leakage can be proved experimentally by a method due to Mordey, by placing a pair of thermometers, one of mercury and the other of alcohol, in the centre of the core aperture. If there is magnetic leakage, the mercury bulb is heated not only by radiant heat, but by eddy currents set up in the mercury, and its rise is therefore greater than that of the alcohol thermometer. The leakage is also determined by observing the secondary voltage drop between full load and no load, and deducting from it the part due to copper resistance; the remainder is the drop due to leakage. Thus if V_2 is the secondary voltage on open circuit, and V_2^1 that when a current A_2 is taken out of the transformer, the leakage drop v is given by the equation

$$v = (V_2 - V_2^1) - \{R_2A_2 + R_1\left(\frac{N_2}{N_1}\right)^2 A_2\}.$$

The term in the large bracket expresses the drop in secondary voltage due to the copper resistance of the primary and secondary circuits.

In drawing up a specification for an alternating current transformer, it is necessary to specify that the maximum secondary drop between full and no load to be allowed shall not exceed a certain value, say 2 per cent. of the no-load secondary voltage; also that the iron core loss as a percentage of the full secondary output shall not exceed a value, say, of 1 per cent. after six months' normal work.

Transformer design.

In the design of large transformers, one of the chief points for attention is the arrangement for dissipating the heat generated in their mass by the copper and iron losses. For every watt expended in the core and circuit, a surface of 3 to 4 square inches must be allowed, so that the heat may be dissipated. In large transformers it is usual to employ some means of producing a current of air through the core to ventilate it. In these, called *air-blast transformers*, apertures are left in the core by means of which the cooling air can reach the interior portions. This air is driven through the core by a fan actuated by an alternating current motor, which does not, however, take up power to a greater extent than about one-quarter or one-tenth per cent. of the full output of the transformer, and well repays the outlay.

In some cases transformers are *oil-insulated*, that is to say, included in a cast-iron box which is filled in with a heavy insulating oil. For this purpose an oil must be selected free from mineral acids and water: it should be heated to a high temperature before use, and tested for dielectric strength by observing the voltage required to create a spark between metal balls immersed in it at a distance of 1 millimetre apart. Oils, however, are inferior in dielectric strength or spark-resisting power to solid dielectrics, such as micanite, ebonite, &c., as shown by the following table of dielectric strengths (see T. Gray, *Phys. Rev.*, 1898, p. 199).

Polyphase transformers are appliances of similar construction to the single-phase transformers already described, but modified so as to enable them to transform two or more phase-related primary alternating currents into similar secondary currents. Thus, a three-phase transformer may be constructed with a core, as shown in Fig. 8. Each core leg is surrounded with a primary coil, and these are joined up either in star or delta fashion, and connected to the three or four line wires. The secondary circuits are then connected in a similar fashion to three or four secondary lines. In the case of two-phase transmission with two separate pairs of leads, single-phase transformers may be employed in each branch, but with two-phase three-wire supply, two-phase transformers must be supplied.

Phase transformers are arrangements of static or rotatory transformers intended to transform single-phase

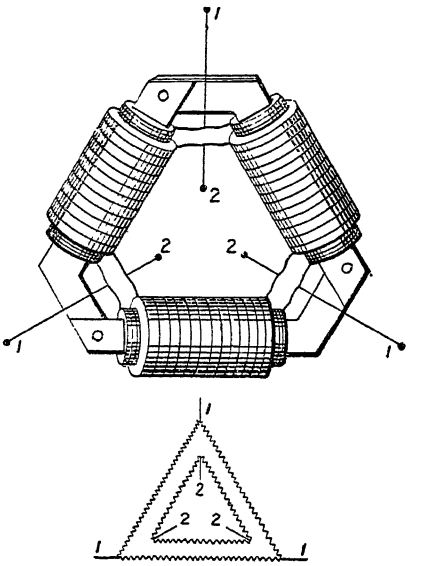

FIG. 8.—Three-phase Transformer.

alternating currents into polyphase currents. An important system of phase transformation has been described by Mr C. F. Scott.[1] It is well known that if two alternating electromotive forces differing in phase are connected in series, the resulting electromotive force will in general differ in phase and value from either of the components.

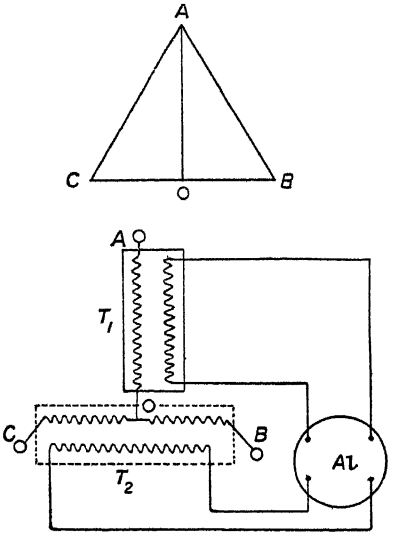

FIG. 9.—Scott's arrangement for transformation of two-phase to three-phase currents.

Thus, if two alternating electromotive forces differing 90° in phase, and having magnitudes in the ratio of $1 : \sqrt{3}$, are connected in series, the resulting electromotive force will have a magnitude represented by 2, and the three can be

[1] *Proceedings of the National Electric Light Association*, Washington, U.S.A., 1894; also *Electrician*, vol. xxxii. p. 640, 1894.

represented by the sides of a triangle which is half an equilateral triangle. If then a two-phase alternator, D, (Fig. 9) provides two-phase currents, and if the two circuits are connected, as shown, to a pair of single-phase transformers, T_1 and T_2, we can obtain three-phase alternating currents from the arrangement. The primaries of both transformers are the same. The secondary circuit of one transformer, T_2, has, say, 100 turns, and a connexion is made to its middle point O, and this is connected to the secondary of the other transformer which has 87 ($=50\sqrt{3}$) turns. From the points A, B, C we can then tap off three-phase alternating currents. The advantages of the Scott system are that we can transform two-phase alternating currents into three-phase for transmission, and then by a similar arrangement retransform back again into two-phase for use. In this manner an economy of 25 per cent. in copper is effected, for instead of four transmission lines we only have three. The system adapts itself for the transmission of currents both for power in driving three-phase motors and for working incandescent lamps. A somewhat similar system has been designed by Mr C. P. Steinmetz for producing three-phase currents from single-phase (see *Electrician*, vol. xliii. p. 236.) When a number of alternating electromotive forces are maintained in a closed circuit, the sum of all must be zero, and may be represented by the sides of a closed polygon. The fundamental principle of Mr Steinmetz's invention consists in so choosing the number of these electromotive forces that the polygon must remain stable. Thus, if three single-phase alternators are driven independently at constant speed and excitation, and if they are joined in series, then three wires led away from the junction points will provide three-phase currents to a system from which lamps and motors may be worked.

Reference must be made in the next place to the continuous current transformer. The conversion of a continuous current supplied, say, at 100 volts, into one having an electromotive force of 10 volts, can of course be achieved by coupling together on the same bedplate a suitable electric motor and a dynamo. The combination is called a *motor-dynamo set*, and each machine preserves its own identity and peculiarity. The same result may, however, be accomplished by winding two separate armature circuits on one iron core, and furnishing each with its own commutator. The two circuits are interlaced or wound on together. An arrangement of this kind constitutes a *rotatory transformer*, or continuous current transformer. It has the advantage of greater cheapness and efficiency, because one field magnet serves for both armature windings, and there is only one armature core and one pair of bearings; moreover, no shift or lead of the brushes is required at various loads. The armature reactions of the two circuits annul each other. Machines of this description are self-starting, and can be constructed to take in primary current at high pressures, say 1000 to 2000 volts, and yield another larger current of much lower voltage, say 100 or 150 volts, for use with electric lamps. They are used in connexion with public electric supply by continuous current in many places.

Continuous current transformers.

Another important class of rotatory transformer is that also called a *rotatory converter*, by means of which continuous current is translated into alternating current of one-, two-, or three-phase, or *vice versâ*. The action of such an appliance may best be understood by considering the simple case of a Gramme ring armature (see DYNAMO) having, in addition to its commutator, a pair of insulated rings on its shaft connected with opposite ends of the armature winding (Fig. 10). If such a ring is placed in a bipole field magnet, and if a pair of brushes make contact with the commutator C and another pair with the two rings called slip rings, S_1 S_2, and if continuous current at a constant voltage is supplied to the commutator side, then the armature will begin to revolve in the field, and from the brushes in contact with the slip rings we can draw off an alternating current. This reaches its maximum value when the points of contact of the rings with the armature circuit pass the axis of commutation, or line at right angles to the direction of the magnetic field, for it has at this moment a value which is double the steady value of the continuous current being poured into the armature. The maximum value of the electromotive force creating this alternating current is nearly equal to the electromotive force on the continuous current side. Hence if A is the maximum value of the continuous current put into the armature and V is the value of the brush potential difference on the continuous current side, then 2A is the maximum value of the outcoming alternating current and V is the maximum value of its voltage. Hence $2AV/2 = AV$ is the maximum value of the outcoming alternating current power, and if we neglect the loss in the armature for the moment, the power given out is equal to the power put in. Hence, assuming a simple harmonic law of variation, the effective value of the alternating current voltage is $V/\sqrt{2}$, and that of the alternating current is $2A\sqrt{2}$. This conclusion follows at once from the fact that the mean value of the square of a sine function is half its maximum value, and hence the R.M.S. value is $1/\sqrt{2}$ times the maximum value. The outcoming alternating current has its zero value at the instant when the ends of the diameter of the axis to which the rings are connected are in the direction of the magnetic field of the transformer. Hence the power output on the alternating current side varies from a maximum value AV to zero. The rotatory transformer thus absorbs continuous current power and emits it in a periodic form; accordingly, there is a continual storage and emission of energy by the armature, and therefore its kinetic energy is periodically varying during the phase. The armature is also creating a back-electromotive force which acts at some instants against the voltage driving the current into the armature and at others is creating an electromotive force that assists the external impressed voltage in driving a current through the alternating current side. If we put on another pair of insulated rings and connect them to points of the insulated diameter at right angles to the points of connexion of the first pair of rings, we can draw off another alternating current, the phase of which differs 90 degrees from that of the first. Similarly, if we provide three rings connected to points removed 120 degrees apart on the armature circuit, we can tap off a three-phase alternating current.

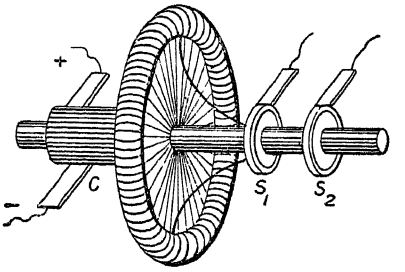

FIG. 10.—Converter, continuous to two-phase.

Returning to the case of the single-phase rotatory transformer, we may notice that at the instant when the outcoming alternating current is zero the armature is wholly engaged in absorbing power and is acting entirely as a motor. When the alternating current is a maximum, the armature on the other hand is acting as a generator and adds current to the current put into it. The ratio

between the potential difference of the brushes on the continuous current side and the root-mean-square or effective value of the voltage between any pair of rings on the alternating current side is called the transformation ratio of the converter.

The following table, taken from a paper upon rotatory converters by Professor S. P. Thompson (*Proc. Inst. Elec. Eng.*, November 1898), gives the voltage ratio or conversion ratio in the case of various forms of rotatory transformer :—

Number of slip rings.	Angle between points of connexions to armatures.	Type of current generated.	Voltage ratio.	Effective voltage on alternating current side as percentage of voltage on continuous current side.
2	180 deg.	Single-phase	$\sqrt{2} : 1$	70·71
3	120 ,,	Three-phase	$2\sqrt{2} : \sqrt{3}$	61·23
4	90 ,,	Two-phase	$\sqrt{2} : 1$	70·71
4	90 ,,	Four-phase	$2 : 1$	50
6	60 ,,	Three-phase	$3\sqrt{3} : \sqrt{3}$	61·23
6	60 ,,	Six-phase	$2\sqrt{2} : 1$	35·35

Neglecting the energy losses in the armature, and assuming that the continuous current side of the transformer is supplied with 100 amperes, the following table, also taken from a paper by Professor S. P. Thompson, shows the effective value of the current on the alternating side put out into each line :—

Number of slip rings.	Angle between points of connexion to armature.	Type of current generated.	Effective current put out on each line in amperes.
2	180 deg.	Single-phase	141·4
3	120 ,,	Three-phase	94·3
4	90 ,,	Two-phase	70·7
6	60 ,,	Six-phase	47·2

It is obvious that the same results of conversion can be obtained by coupling together two separate machines on the same shaft; thus we might obtain a single-phase alternating current from a continuous current by coupling together mechanically a continuous current motor and a single-phase alternator. Such a combination is generally called a *motor-dynamo*. In this case there are two field magnets and two separate armatures, and the hysteresis eddy current and copper losses are all in duplicate. If, however, the same armature winding is made to serve both purposes, the resulting machine is called a *rotatory* or *rotary converter*. In the former combination the brushes of the continuous current part require to be set with the usual lead or lag according as that part is generator or motor, but in the latter the armature reactions nearly annul each other, and lead or lag is no longer necessary. The fact was pointed out by S. P. Thompson, in connexion with continuous current transformers (*Phil. Mag.*, August 1888). One objection to the rotatory converter arrangement, as above described, is the rather awkward fractional values of the conversion ratio. An ingenious modification of the single armature winding for obviating this difficulty has been described by Heldt (*Electrical World*, vol. xxviii., 1896).

Rectifiers. Finally, a brief allusion must be made to *rectifiers*, which are devices for transforming an alternating (generally single-phase) current into a continuous but pulsatory current. They may shortly be described as appliances for separating out each alternate current flux in an alternating current. An immense number of more or less imperfect methods of doing this have been proposed, but we have merely space for allusion to two which may be called respectively the mechanical and the electrolytic methods. Of the first class a good example is the Ferranti rectifier (Fig. 11). This consists of a synchronous alternating current motor which is started up and driven in step with the alternator supplying the current. The motor drives a commutator of insulated segments, each alternate segment being connected to two insulated rings, against which press a pair of brushes. Another pair of brushes, so adjusted as to be in contact simultaneously with a pair of adjacent commutator segments, are in connexion with the alternator supplying the current to be commutated. The insulated rings are in connexion with the external circuit. It will easily be seen that when the commutator revolves at proper speed the currents delivered from the insulated

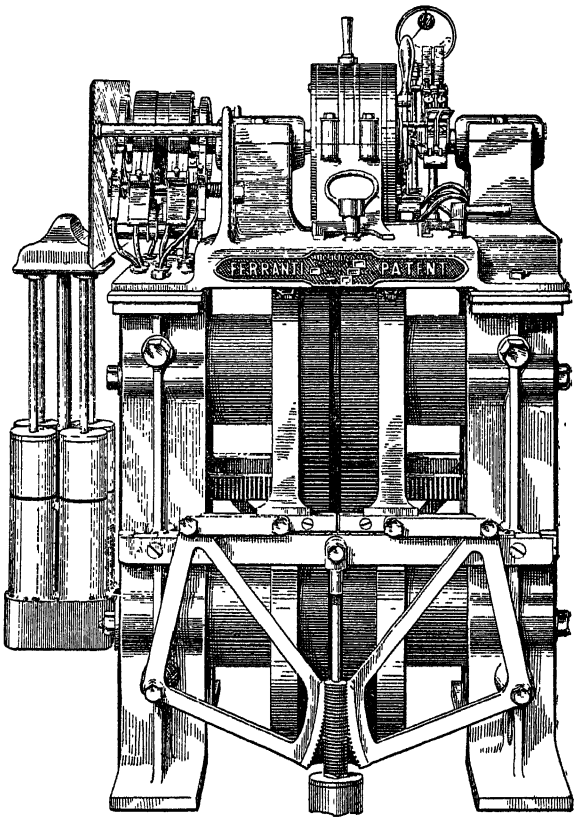

FIG. 11.—Ferranti Rectifier.

rings are unidirectional. The Ferranti rectifier is much employed for rectifying alternating current for arc lighting purposes. With this object it is associated with a constant current transformer which converts alternating current supplied at constant potential to one supplied at constant current. This is achieved by taking advantage of the repulsive force existing between the primary and secondary circuits of a transformer. These are wound separately, and so balanced that any increase in the current presses them away from each other and so reduces the secondary current to normal value. An appliance of the above description is useful for rectifying currents up to 10 or 15 amperes, but with larger currents it becomes troublesome, owing to the excessive sparking at the contacts.

The electrochemical rectifier is based upon a phenomenon originally discovered by Buff in 1857 (*Lieb. Ann.*, lii. p. 296, 1857), and rediscovered by Ducretet in 1874 (*Comptes Rendus*, lxxx. p. 280, 1874). If plates of aluminium and carbon are placed in an electrolyte, say a solution of alum or dilute acids which yield oxygen on electrolysis,

it is found that a current can be sent through the liquid from the carbon to the aluminium, but that great counter-electromotive force is created to a current in the opposite direction. Grätz and Pollak (*Elektrotechnische Zeitschrift*, 25, p. 359, 1897), taking advantage of this fact, have constructed a rectifying arrangement by arranging two series of carbon-aluminium (CAl) cells with alum or hydro-potassic phosphate solution as electrolyte. In one set the order of the plates is (CAl), (CAl), &c., and in the other series (AlC), (AlC), counting from the same end. These series being connected in parallel, it follows that if an alternating current is sent through the parallel series all the currents in one direction pass through one battery and all those in the opposite direction through the other. Thus the constituents of the alternating current are separated out. By using very large cells so as to reduce the internal resistance, an efficiency of 95 per cent. is said to be obtained. The first application of the unilateral conductivity of aluminium-carbon cells for the rectification of alternating currents was probably made by Hutin and Leblanc (*Études sur les courants alternatifs et leurs applications industrielles*, part ii. chap. x. p. 135; also French Patent No. 215945, 1891).

Theory of electrolytic rectifier.

The theory of the electrolytic rectifier has engaged the attention of a great many investigators, and although some progress has been made towards the elucidation of its action and in its application in electrotechnics, as illustrated by the numerous patents issued during the last few years, there are many points in its operation which have as yet been imperfectly explained. The action of the aluminium electrolytic rectifier, consisting as it does of an aluminium plate and a lead or carbon plate placed in an aqueous electrolyte, is to oppose a great obstruction to a current passing out of the aluminium plate, but little or no obstruction to the current passing into the aluminium plate, especially if the aluminium has been subjected to a previous treatment called *formation*. This unilateral conductivity is dependent on a certain voltage or potential difference between the plates not being exceeded, but within these limits a plate of carbon and aluminium placed in a solution, say of hydrosodic phosphate, acts as an electrical *valve*, allowing current to pass in one direction but not in another. An examination of the aluminium plate after it has been so used shows that its appearance has changed and that its surface is covered by a thin film, the thickness of which varies with the electrolyte and the time of formation. After a certain period of use this film is seen as a grey, dull coating traversed by dark lines. It is impossible that the unilateral conductivity can be due to a true electrolytic polarization, because we know of no polarization of this latter kind which exceeds three volts, and the film can be made to resist the flow of a current under an electromotive force of 140 to 200 volts. The resistance of this film has been measured and found to be very high, so high as to be practically an insulation. Light was thrown upon the subject by F. Kohlrausch's discovery of the polarization capacity of metallic electrodes, and this discovery was applied to develop the theory of the aluminium cell by Streintz (1888), Scott (1899), and others.

This theory was expounded by Dr K. Norden in an article on the electrolytic rectifier (see the *Electrician*, vol. xlviii. p. 107). According to this view, the deposit covering the aluminium electrode forms the dielectric of a condenser. One plate of the condenser is formed by the aluminium plate and the other by an opposite layer of electrically-charged ions in the electrolyte. The dielectric film on the aluminium having been formed, the electromotive force of the circuit then charges the resulting condenser to the value of its own voltage, but immediately the impressed electromotive force is removed this condenser discharges itself. This condenser theory receives support from the behaviour of the aluminium cell when placed in the circuit of an alternating current dynamo, for it is found that in these circumstances the current through the cell is in advance in phase of the difference of potential. The question then arises, What is the nature of this insulating film? The first discoverer of the phenomenon (Buff) considered it to consist of silicon. Later Professor Beetz disproved this by experiment, and, with many others, assumed that a sub-oxide of aluminium was formed; but this has never been demonstrated in a satisfactory manner. By forming a sufficient quantity of the film Dr K. Norden was able to obtain sufficient of the material to make a chemical analysis, and this revealed the fact that it consists of normal aluminium hydroxide, $Al_2(OH)_6$.

According to the facts above stated, one wave of the alternating current produces the insulating film by converting the surface of the aluminium into hydroxide, practically, therefore, blocking its own path very quickly by the creation of this film. If, then, the electromotive force reverses its direction, the current immediately flows. According to Dr Norden, the rapid removal of the insulating film is due to the action of the electrolyte corroding or dissolving the weak points in the coating and thus breaking down its insulating power. The insulating film is therefore a conductor in one direction, but when the current is reversed and flows out of the aluminium plate, the insulating film is renewed and is continually being repaired and kept in order. Thus different electrolytes yield aluminium valves having very different efficiencies.

Rectifying cells have been made by Pollak which will bear a voltage of over 140 volts, and which are said to have an efficiency of 75 per cent. The plates, however, must be removed when not in use, otherwise the film of hydroxide is destroyed by the electrolyte. One great practical difficulty in connexion with the aluminium rectifier is the tendency to heat in working, and as the temperature cannot be allowed to exceed 104° F. without producing ill effects, it is necessary to employ a cell many times larger than the plate it contains in order that there may be a sufficient amount of liquid to keep down the temperature. In any event, after 500 to 800 hours' working the aluminium plate becomes furrowed and in the end falls to pieces. These difficulties have not so far been overcome as to make the aluminium valve of any great practical utility. At its first introduction it was hailed as a practical means of obtaining direct currents from alternating currents for the purpose of charging accumulators and doing other chemical work, but although it has been employed in this manner to a limited extent, considerable improvements must be made before it can realize all the expectations which were once formed concerning it.

The historical development of the discovery of this unilateral conductivity of an electrolytic cell with an aluminium electrode is as follows. The effect was first noticed by Buff in 1857, but was not applied technically until 1874, when Ducretet employed it in telegraphy. Beret in 1877 and Streintz in 1887 discussed the theory of the cell and sought for an explanation. In 1891 Hutin and Leblanc, in their study of alternating currents, showed its uses in rectifying an alternating current. Pollak and Grätz laboured to give it a practically useful form. Pollak took out patents in 1895, and made a communication to the Academy of Sciences in Paris in June 1897; and Grätz presented a memoir at a meeting of the German Association of Electrochemists in Munich in 1897. M. Blondin has summarized all the work so far done on the aluminium rectifier in two articles in *L'Éclairage Électrique*, vol. xiv. (1898) p. 293, and vol. xxviii. (1901) p. 117. The choice of an electrolyte is of great importance. Buff, Ducretet, and Grätz employed dilute sulphuric acid, and the greatest difference of potential which could then be applied to the cell without breaking down its insulation in one direction was 20 volts. Pollak in 1896 found that when aqueous solutions of alkaline salts were used, and when the aluminium plate was subjected to a preliminary formation, the back electromotive force or what is equivalent to it could be raised to 140 or 200 volts. Pollak found that the best results were given by the use of phosphate of potassium or sodium. It appears, therefore, that the ions of K or Na effect the breaking down of the film of aluminium hydroxide more quickly than the ion of hydrogen. The practical form of aluminium rectifier, according to Pollak, consists of plates of thick aluminium and lead placed in a large deep glass vessel filled with a solution of hydro-potassic phosphate.

Induction coils.

The ordinary induction or spark coil may be said to perform the operation of converting an intermittent low-tension continuous current into an intermittent high-tension one. An impetus has been given of late to the manufacture of large spark coils by the demand for them in Röntgen ray and wireless telegraph work. A modern induction coil for the production of long sparks is constructed as follows:— The primary coil consists of two or more layers of insulated wire wound on an iron core formed of a bundle of well annealed iron wire. This coil and core are entirely enclosed in a thick ebonite tube, leaving openings only for the entrance and exit of the primary coil and for a soft iron cylinder which is in magnetic connexion with the iron core. Over this tube is slipped a series of flat coils generally made of shellacked paper, the wire winding being in two vertical layers separated by an insulating disc. In this way the two ends of the coil are brought to the outside. These flat coils are electrically joined up so as to make one continuous bobbin of wire in which the insulated wire is so disposed that parts of the wire near to each other are not very different in potential. This secondary winding is likewise enclosed in an ebonite tube. The coil is completed by a contact breaker and condenser. The former is an automatic vibrator on the principle of the vibrating hammer of an electric bell, which is actuated by the magnetism of the core and interrupts the circuit of the primary coil. The condenser consists of interleaved sheets of tin-foil and paraffined paper, the alternate sheets of foil being connected together. This condenser is connected across the break to the two

platinum points between which the rapid interruption of the primary circuit takes place. The function of the condenser is to assist in rapidly demagnetizing the core, and in destroying the electric spark between these points as they separate. When the contact points are together the condenser is discharged but the core is magnetized. When the contact points separate the condenser is charged through the primary coil, and the charge takes place by a series of electrical oscillations which rapidly remove the remanent magnetism of the core. As the electromotive force in the secondary circuit depends on the rate at which the flux of magnetic induction is removed from the core, the condenser has a remarkable effect in increasing the secondary electromotive force at the break of the primary current. Accordingly the electromotive forces set up in the secondary circuit at *break* and at *make* of the primary circuit are very different in value, the former being enormously greater than the latter. Hence, when the secondary circuit is interrupted by a spark gap and the primary current is intermitted, the secondary discharges are also intermittent and unidirectional, being those which correspond with the break of the primary current. Lord Rayleigh has, however, shown that if the primary circuit is interrupted with great rapidity, as by severing it with a bullet, the secondary spark of the coil may be even longer without the condenser across the break gap. The E.M.F. of the secondary is then greatly increased (see *Phil. Mag.*, December 1901, p. 581).

The manufacture of very large induction coils is a matter requiring great care and experience. The reader may be referred for details to a book by Mr A. T. Hare on *The Construction of Large Induction Coils* (London, 1900). Also for details of many large historical induction coils see *The Alternate Current Transformer* (Fleming, vol. ii.). If the induction coil has a condenser, such as a Leyden jar, connected across its secondary terminals, the sparks produced become much shorter and brighter, but more intermittent and noisier. The current flowing from the secondary circuit charges the condenser, and hence at each discharge a much larger quantity of electricity passes than when the condenser is not used. The reason the spark lengths are so much reduced is as follows:—To charge a condenser of capacity C to a voltage V through a resistance R, the electromotive force must be applied steadily for a period at least equal to ten times the value of the product C R, where R is measured in megohms and C in microfarads. If the condenser is a Leyden jar having, say, 1 square foot of contact surface, the glass being about 1/10th of an inch thick, then the capacity will be approximately 1/400th of a microfarad. The resistance of the secondary circuit of a 6-inch spark coil is usually about 10,000 ohms, or 1/100th of a megohm. Hence, the product C R, or the time constant of the jar circuit, is 1/4000th of a second. Now the vibrating break of the induction coil may make from 20 to 50 oscillations per second, and the time during which the secondary electromotive force in the coil has approximately its maximum value, or value corresponding to the ordinary spark length, is probably less than 1/100th of the time period of the break. Accordingly, the electromotive force of the coil is applied to the jar for a time too short to charge it up to the potential which corresponds to the full ordinary spark length (6 inches) of the coil.

The oscillatory discharges produced by discharging a large condenser through a low resistance can be transformed in potential, and we can construct an oscillation transformer. This is usually called a Tesla coil, but Mr Tesla was not by any means the first person to transform by induction the oscillatory discharges of a Leyden jar. A length of copper wire is coiled on an insulating cylinder in one layer, the turns being preferably separated by a silk cord. Over this is placed another cylinder of glass or ebonite, and on this second cylinder another coil of fine wire is wound in one layer. If the primary coil of the above arrangement is connected in series with a Leyden jar or battery of jars, and the two together connected across the secondary terminals of an ordinary induction coil, the spark balls of which are separated by a few millimetres, then loud rattling discharges of the jar take place when the induction coil is worked. These discharges are oscillatory, and consist of groups of rapidly alternating currents flowing through the primary circuit of the oscillation transformer; these oscillations are transformed up in potential by the secondary circuit, and from these latter terminals we can draw off a secondary discharge of higher potential and much higher frequency than the ordinary secondary spark of the induction coil (see TELEGRAPHY: *Wireless*). These high potential, high frequency discharges produce many interesting effects, and can be passed through the human body without producing painful shock. The secondary terminals of the oscillation transformer produce powerful brush discharges in air when separated beyond their sparking distance, and also very brilliant discharges through highly exhausted vacuum tubes.

TRANSVAAL COLONY.

I. GEOGRAPHY AND STATISTICS.

TRANSVAAL Colony, formerly the SOUTH AFRICAN REPUBLIC, Africa, lies between 22° and 28° S. and 25° and 32° E. The boundaries laid down by the Convention of 27th February 1884 were modified by the Conventions of 1894 and 1897 relating to the district of Vryheid and the territory of Swaziland, and in 1902 as the result of the extension of Natal (*q.v.*). As thus delimited the Transvaal presents the outlines of an irregular oblong disposed in the direction from south-west to north-east, and truncated in the north by the east to west direction of the Limpopo, which forms the frontier river towards Bechuanaland and southern Rhodesia as far as the Limvubu confluence. The southern boundary coincides with the Vaal and its Klip headstream as far as Natal, where it follows the Drakensberg range to the head-waters of the Pongola river, which it follows to the border of the Utrecht district, while the Lobombo range forms the dividing line towards Zululand and Portuguese territory northwards to the Limvubu confluence. From this point to the lower Vaal at Platberg there was, before the alteration of the boundary, an extreme length of about 500 miles, and a breadth of nearly 400 miles from the western border near Mafeking to Komati Poort, where the Delagoa Bay railway enters the Transvaal from Portuguese territory. Within these limits there is a total area of about 126,000 square miles, and a population approximately estimated in 1898 at 1,094,000, of whom about 245,000 were whites, mostly Boers and British, and 748,000 natives of Bantu (Zulu and Bechuana) stock and speech. Some 8000 whites and 50,000 natives were added by the 1902 rectification of the frontier.

Mineral Wealth.—The Transvaal is one of the most highly mineralized regions in the world. The gold-bearing reefs are widely distributed over the whole land, ranging from Lydenburg, De Kaap, Komati, Barberton, and Swaziland in the extreme east to the Marico district in the extreme west, and from the Zoutpansberg and Murchison Hills in the north to Rustenburg, Krugersdorp, Schoonspruit, Rooderand, and especially the Witwatersrand ("The Rand," with chief centre Johannesburg) in the south. Although many of the reefs in these districts have scarcely yet been tapped, the annual output rose

from £2,924,000 in 1891, from which year date the first official returns, to £8,570,000 in 1895 and no less than £16,044,000 in 1898, the year before the outbreak of hostilities. The total yield from 1884 to 1900 probably exceeded £80,000,000, while with the institution of orderly government it is expected that at least 20,000,000 tons of quartz will be annually dealt with on the Rand alone. But the mineral resources of the Transvaal are by no means confined to gold. Diamonds are found in the Pretoria district and other places, and in 1898 the product exceeded 22,000 carats, valued at nearly £44,000. Extensive deposits of good coal, including some very thick seams of steam coal, occur near the Rand and other goldfields, and although mining operations are yet in their infancy, the output rose from 1,437,000 tons in 1896 to 1,600,000 in 1897 and 1,907,000 in 1898. It appears that the rich Carboniferous beds of the Newcastle district in northern Natal extend with little interruption northwards far into the Vaal basin, and are already used by Boer farmers for domestic purposes. Like that of Newcastle, the Transvaal coal burns with a clear flame and leaves little or no ash. Amongst other mineral treasures are lead, sulphur, cobalt, saltpetre, iron, and copper. The last two are widely distributed, and the Yzerberg, "Iron Mountain," near Marabastad, which is now reached by rail from Pretoria, consists of a huge mass of exceedingly rich iron ore, which has been smelted and wrought into divers implements by the natives from the remotest times.

Agricultural Resources.—The agricultural prospects of the country, including both tillage and stock-breeding, are also much brighter than is commonly supposed. Husbandry, however, is still in a very backward state, and in 1898 not more than 50,000 acres altogether had been brought under cultivation. There are no doubt over 12,000 farms, averaging about 6000 acres each, but the Boers are essentially stock-breeders, and cultivate very little land, not enough even for the local demand, so that cereals and other produce have to be imported in considerable quantities—corn, vegetables, preserves, &c., to the value of £1,200,000 in 1898. All this and much more might be grown several times over in the country itself, where the Potchefstroom and Pretoria districts are specially suited for cereals, fruits, tobacco, the vine, and vegetables; Rustenburg, with its sub-tropical climate, for cereals, ground-nuts, tobacco, coffee, cane-sugar, bananas, and oranges; Lydenburg, for cereals, tobacco, sugar, and coffee; and all or most of these crops might also be easily raised in the Marico, Middelburg, Waterberg, and several other districts. The great drawbacks are the tsetse-fly, which, however, is mainly confined to the swampy tracts in the middle and lower Limpopo valley; horse-sickness, which is being dealt with apparently with some success; the locust plague, which might be abated by such measures as those adopted in Cyprus and Algeria; lastly, the deficient rainfall, which it is proposed to neutralize to some extent by regulating the discharge of the Vaal and Limpopo affluents, and husbanding the flood-waters which now run waste. By these and other irrigation works it is calculated that, as in Cape Colony, many hundred thousand acres of land now arid might be brought under cultivation.

Trade, &c.—No accurate returns are available for the exports, which consist chiefly of gold, wool, cattle, hides, grain, ostrich feathers, ivory, and minerals. The total exports rose from 8500 tons in 1895 to 51,400 tons in 1898, and of this quantity (value not stated) 47,645 tons represented such local produce as coal (38,800 tons), wool (2540), hides and skins (2100), ores (1920). The imports advanced from £6,440,000 in 1894 and £9,816,000 in 1895, to £14,088,000 in 1896; but owing to the political unrest fell to £13,564,000 in 1897 and £10,633,000 in 1898, and in 1901 to £3,670,000, but this was exclusive of Government and military supplies. They consist chiefly of machinery, cottons, clothing, chemicals, cutlery, provisions, haberdashery, and furniture. In 1898, of the total imports £6,332,000 came from Europe, £1,159,000 from Cape Colony, £1,203,000 from Natal, £537,000 from the Orange Free State, £537,000 from Lourenço Marquez, and £481,500 from America and other countries. The revenue rose from £1,703,000 in 1893 to £4,807,000 in 1896, and then fell to £4,480,000 in 1897 and £3,984,000 in 1898, the expenditure being for the corresponding years £1,302,000, £4,671,000, £4,394,000, and £3,971,000. The communications are still in a backward state, the roads especially being generally very rough. But railway enterprise has made some progress since the development of the gold-mining industry. In 1898 there was a total length of 774 miles open, connecting Pretoria with the Cape through Bloemfontein, with Durban through Standerton, Newcastle, and Ladysmith, with Delagoa Bay through Middelburg and Komati Poort, with Johannesburg, Pietersburg, and other places by branch lines ramifying from the capital. In the same year 270 miles were in progress and 250 projected.

II. History.

From the time of the Great Trek out of Cape Colony to lands north of the Vaal river in 1833–37, down to the Sand River Convention in 1852, the history of the Transvaal Boers was one of continued strife with the natives. The Apprentice Law of 1856 practically legalized slavery, and the opposition which this measure excited in the minds of many Englishmen was one of the most fertile causes of irritation between the Boers and the British authorities. Apart from the Trek Boers' attitude towards the natives, their history in the Transvaal until 1877 shows that they carried with them to their new home a spirit hostile not merely, as has been represented by many writers, to British rule, but to civilized rule in any shape or form. They and their fathers had, while still resident in the frontier districts of the colony, rebelled first of all against the government of the Dutch East India Company, and at a later date against the British Government, because they resented in both cases any interference with their relations either to the natives or to one another. Governments within the Transvaal appointed by themselves, as a review of their history will show, fared no better, but even worse than those from the rule of which the Boers had withdrawn.

Earlier years.

In 1856 a series of public meetings among the Boers, summoned by Commandant-General M. W. Pretorius, was held at different districts in the Transvaal for the purpose of discussing and deciding whether the time had not arrived for abolishing the system of petty district governments which had hitherto existed. The result was that a representative assembly of delegates was elected, empowered to draft a constitution. In December this assembly met at Potchefstroom, and for three weeks was engaged in modelling the constitution of the country. The new constitution made provision for a Volksraad to which members were to be elected by the people for a period of two years, and in which the legislative function was vested. The administrative authority was to be vested in a President, aided by an executive council. It was stipulated that members both of assembly and council should be members of the Dutch Reformed Church. In reviewing an incident so important in the history of the Transvaal as the appointment

Potchefstroom assembly, 1856.

of the Potchefstroom assembly, it is of interest to note the gist of the complaint among the Boers which led to this revolution in the government of the country as it had previously existed. In his *History of South Africa*, Theal says, "The community of Lydenburg" (the oldest district government) "was accused of attempting to domineer over the whole country, without any other right to pre-eminence than that of being composed of the earliest inhabitants, a right which it had forfeited by its opposition to the general weal." In later years this complaint was precisely that of the Uitlanders at Johannesburg. In order to endeavour to conciliate one of these district governments at Zoutpansberg, the new-born assembly at Potchefstroom appointed Mr Schoeman, a commandant of the Zoutpansberg district, commandant-general. This offer was, however, declined by Schoeman, and both Zoutpansberg and Lydenburg indignantly repudiated the new assembly and its constitution. The executive council, which had been appointed by the Potchefstroom assembly with Pretorius as President, now took up a bolder attitude: they deposed Schoeman from all authority, declared Zoutpansberg in a state of blockade, and denounced Boers of the two northern districts as rebels.

In order further to strengthen their position, Pretorius and his party also endeavoured to bring about a union with the Free State. With this intention they sent emissaries to the Free State Government to make overtures on the subject. These overtures were rejected. Nothing daunted, Pretorius determined to win by force what he had failed to obtain by persuasion. There was a certain number of Free State Boers prepared to accede to the proposals of Pretorius, and relying on their aid, Pretorius entered into an intrigue to overthrow the President of the Free State, Boshof, and his Government. Pretorius placed himself at the head of a commando and crossed the Vaal, being joined by a certain number of Free State burghers. On learning of the invasion, President Boshof immediately took energetic measures to defend his country. He proclaimed martial law, called out his burghers, and marched towards Kroonstad to meet the invaders. At the same time Boshof received an offer from the outraged and deposed General Schoeman of Zoutpansberg to gather a force and come to his assistance. The forces of Pretorius and Boshof at length faced each other on opposite banks of the Rhenoster river. Threatened from the north as well as the south, Pretorius now recognized that he was engaged in a dangerous enterprise. He had as his lieutenant on this occasion no less a personage than Mr Stephanus Johannes Paulus Kruger, and to Mr Kruger was entrusted the task of bearing a flag of truce to the Free Staters, with an expression of hope that a peaceful settlement might be arrived at. A treaty, containing an apology from Pretorius, was agreed upon, and the invading force withdrew. By the year 1860, the foregoing events notwithstanding, Zoutspansberg and Lydenburg had become incorporated with the republic. Schoeman had accepted the post of commandant-general, and Pretoria was made the seat of Government and capital of the country. The state was now apparently united, and the Government founded on the will of the people. The Separatist Church of Holland in the year 1858 sent out a young expositor of its doctrines named Postma. This minister settled at Rustenburg and founded the first branch of the Dopper sect, a sect which has since become famous in the Transvaal, as well as in the Free State and even Cape Colony. The tenets of the Separatist Reformed (or Dopper) Church do not call for close analysis here. It will be sufficient to say that they approached somewhat those held by the Scottish Covenanters. They raised strong objection to the singing of hymns, other than paraphrases of Scripture, as part of the church service. Of this sect Paul Kruger, who resided near Rustenburg, became an adherent.

Presidency of Pretorius.

In 1860 a curious sequel to the invasion of the Free State by Pretorius occurred. Pretorius, while still President of the Transvaal, was elected President of the Free State. He thereupon obtained six months' leave of absence and repaired to Bloemfontein, in the hope of peacefully bringing about a union between the two republics. He had no sooner left the Transvaal than the old Lydenburg party, headed by Potgieter, landdrost of Lydenburg, protested that the union would be much more beneficial to the Free State than to the people of Lydenburg, and followed this up with the contention that it was illegal for any one to be President of the South African Republic and the Free State at the same time. Pretorius, apparently in disgust at the whole situation, resigned. Mr J. H. Grobelaar, who had been appointed President during the temporary absence of Pretorius, was requested to remain in office. The immediate followers of Pretorius now became extremely incensed at the action of the Lydenburg party, and a mass meeting was held at Potchefstroom, where it was resolved that: (*a*) the Volksraad no longer enjoyed its confidence; (*b*) that Pretorius should remain President of the South African Republic, and have a year's leave of absence to bring about union with the Free State; (*c*) that Schoeman should act as President during the absence of Pretorius; (*d*) that before the return of Pretorius to resume his duties a new Volksraad should be elected.

Internal dissensions.

In view of later events, the anarchy which has existed among the Trek Boers, north of the Vaal, from the earliest times demands the closest study, in order that the true character and aspirations of the Boers may be understood. The action of the Volksraad, incited by the jealousies of the old district governments and their followers in Lydenburg and Zoutpansberg, was antagonistic to anything in the shape of a patriotic and truly republican government. If at this stage of their existence the real ambition of the Transvaal Boers was to found a strong and compact republican state, their conduct in opposing a scheme of union with the Free State was foolish to a degree. The events of the year 1860, as well as of all the years that followed down to British annexation in 1877, show that licence rather than liberty, a narrow spirit of faction rather than patriotism, were the dominant instincts of the Boer. Had the fusion of the two little republics which Pretorius sought to bring about, and from which apparently the Free State was not averse, actually been accomplished in 1860, it is more than probable that a republican state on liberal lines, with some prospect of permanence and stability, might have been formed. But a narrow, distrustful, grasping policy on the part of whatever faction might be dominant at the time invariably prevented the state from acquiring stability and security at any stage of its history. On no less than three occasions, unique opportunities were afforded for consolidating and establishing this republic. The first of these occasions we have dealt with. The second occurred in 1887, and the third in 1895. Of these opportunities no advantage was taken.

The complications that ensued on the action of the Pretorius party subsequent to his resignation were interminable and complicated. Some of the new party were arraigned for treason and fined; and for several months there were once more two acting Presidents and two rival governments within the Transvaal. At length Commandant Paul Kruger called out the burghers of

his district and entered into the strife. Having driven Schoeman and his followers from Pretoria, Kruger invaded Potchefstroom, which, after a skirmish in which three men were killed and seven wounded, fell into his hands. He then pursued Schoeman, who doubled on his opponent and entered Potchefstroom. At this stage Pretorius intervened. A temporary peace was no sooner secured than Commandant Jan Viljoen rose in revolt and engaged Kruger's forces. At length in 1864, after a series of intestine quarrels, a conference was held lasting six days, followed by a new election for President, and once more Pretorius was called upon to fill that office. Kruger was appointed commandant-general.

Civil strife for a time was now at an end, but the injuries inflicted on the state were deep and lasting. The public funds were exhausted; taxes, always an abomination to the Transvaal Boer, were not only in arrear, but impossible to collect; and the natives on the borders of the country and in the mountains of the north, taking advantage of the anarchy that prevailed, had thrown off all allegiance to the state. The prestige of the country was practically gone, not only with the world outside, but, what was of still more moment, with her neighbour the Free State, which felt that a federation with the Transvaal, which the Free State once had sought but which it now definitely forswore, was an evil avoided and not an advantage lost. A charge frequently laid at the door of the Boers, at that time and since, was that of enslaving the black races. It is true that laws prohibiting slavery were in existence, but the Boer who periodically took up arms against his own appointed Government was not likely to be, nor was he, restrained by laws. Natives were openly transferred from one Boer to another, and the fact that they were described as apprentices by the farmers did not in the least alter the status of the native, who to all intents and purposes became the property of his master. Missionaries were not at this time allowed to reside wherever they chose in the country, the Boers dreading an inculcation of doctrines among the natives likely to be subversive of their rule. Education, as need hardly be said, was in the 'sixties at a very low ebb. Even institutions for children were few in number, and nothing approaching the standard of a high school existed. The private tutor was a good deal in demand, but his qualifications were of the slightest. An unsuccessful European carpenter or other mechanic or even labourer not infrequently occupied this position. At the various churches such elementary schools as existed were to be found, but they did not profess to teach more than a smattering of the three "R's" and the principles of Christianity.

In 1865 an empty exchequer called for drastic measures, and the Volksraad determined to endeavour to meet their liabilities and provide for further contingencies by the issue of notes. Paper money was thus introduced, and in a very short time fell to a considerable discount. In this same year the farmers of the Zoutpansberg district were driven into laagers by a native rising which for some considerable time they were unable to suppress.

Zoutpansberg native rising, 1865. Schoemansdal, a village at the foot of the Zoutpansberg, was the most important settlement of the district, and the most advanced outpost in European occupation at that time in South Africa. It was just one degree north of the tropic, and was situated in a well-watered and beautiful country. It was used as a base by hunters and traders with the interior, and in its vicinity there gathered a number of settlers of European origin, many of them outcasts from Europe or Cape Colony. They earned the reputation of being the most lawless white inhabitants in the whole of South Africa, and to-day a considerable number of these men or their descendants are still to be found in the northern Transvaal. When called upon to go to the aid of this settlement, which in 1865–66 was sore pressed by one of the mountain Bantu tribes known as the Baramapulana, the burghers of the southern Transvaal objected that the white inhabitants of that region were too lawless and reckless a body to merit their assistance. Attempts on the part of the Government to raise a relief force met with very partial success. At length a small relief party proceeded to the district, but they had no sooner arrived than dissension arose between them and some of the more turbulent spirits of the Zoutpansberg. Ultimately Schoemansdal and a considerable portion of the district were abandoned, and Schoemansdal finally was burnt to ashes by a party of natives. For some time after the destruction of Schoemansdal a settlement continued to exist in the district known as Potgieter's Rust. For ten years it had been occupied by Europeans without ill effects, but in 1870 the inhabitants were attacked with fever, from which nearly the whole community perished. The only village which remained under European occupation after this in the Zoutpansberg was Marabastad, at which the Boer landdrost continued to reside. Meanwhile the public credit and finances of the Transvaal went from bad to worse. The paper notes already issued had been constituted by law legal tender for all debts, but in 1868 their power of actual purchase was only 30 per cent. compared with that of gold, and by 1870 it had fallen as low as 25 per cent. Civil servants, who were paid in this depreciated scrip, naturally suffered considerable distress. The revenue for 1869 was stated as £31,511; the expenditure at £30,836. The discovery of gold at Tati led President Pretorius in 1868 to issue a proclamation extending his territories on the west and north so as to embrace the goldfield, and on the east so as to advance considerably over the Portuguese boundary. This proclamation was followed by protests on the part of Her Majesty's High Commissioner, Sir Philip Wodehouse, as well as on the part of the consul-general for Portugal in South Africa. The boundary on the east was settled by a treaty with Portugal in 1870; that on the west was dealt with in 1871.

The Sand River Convention of 1852 had not clearly defined the western border of the state, and the discovery of gold at Tati to the north-west, together with the discovery of diamonds on the Vaal in 1867, doubtless offered Pretorius every inducement to extend his boundary. Although to-day the great diamond mines are south of the Vaal river, it so happened that the early discoveries of diamonds were made chiefly on the northern bank of the Vaal, near the site of the town now known as Barkly West. This territory was claimed by the South African Republic, by some of the Batlapin tribe, and also by Mr David Arnot, on behalf of Nicholas Waterboer, the chief of the Griquas, a race of bastards sprung from the illicit intercourse between Boers and native women, who had been settled north of the Orange since 1834. In order to settle the boundary question, an arbitration court was appointed, consisting of a Transvaal landrost, Mr O'Reilly, on behalf of the South African Republic, and Mr John Campbell on behalf of the other claimants, with Lieutenant-Governor Keate of Natal as final referee. The two judges disagreed, and the final decision, afterwards known as the Keate award, was given by the referee. The decision was in favour of Waterboer, and conceded to him the boundary line to the north and north-east which his agent Arnot had claimed for him. Following

Keate award.

on this decision, Waterboer offered his territory to Queen Victoria. The offer was accepted, and the territory became British under the title of Griqualand West. The Keate award practically brought Bechuanaland into existence as a separate state, and thus kept the great trade route to the north open to British enterprise.

The award caused a strong feeling of resentment among the Boers, and led to the resignation of President Pretorius and his executive. The Boers now cast about to find a man who should have the necessary ability, as they said, to negotiate on equal terms with the British authorities should any future question of dispute arise. With this view they approached Brand, President of the Free State, and asked him to allow them to nominate him for the Presidency of the South African Republic. To this Brand would not consent. He recognized that, even at this early stage of their history, in addition to having neither credit, nor resources, nor power of organization, the Transvaal Boers were filled with the wildest ideas as to what steps they would take in the future to counteract the influence of Great Britain. A number of them openly advocated a repudiation of such conventions as then existed, the extension of a road to Delagoa Bay so as to exclude British trade, and the establishment of a gunpowder factory. Brand did not, in declining the Transvaal invitation, merely content himself with an official communication. He intimated clearly to many of the leading Tranvaal Boers that in his opinion they were embarking on a rash and mistaken policy. He urged that their true interests lay in friendship with, not in hostility to, Great Britain and the British. Having failed with Brand, the Boers now invited the Rev. Thomas François Burgers, a member of a well-known Cape Colony family and a minister of the Dutch Reformed Church, to allow himself to be nominated. Burgers accepted the offer, and in 1872 was duly elected President. In 1871 gold reefs were discovered in the Zoutpansberg district near Marabastad, and already a few gold-seekers from Europe and Cape Colony began to prospect the northern portions of the Transvaal. The miners and prospectors did not, however, exceed a few hundred in number for several years, and it was not until 1882 that they began to make themselves felt as a political and an important commercial factor in the development and future of the country.

Burgers becomes President, 1872.

The appointment of Burgers to the Presidency in 1872 was a new departure. Hitherto the Boers had always chosen one of their own number as President, but in Burgers they had selected a man from outside for the express purpose of securing an educated and capable leader. In a measure Burgers may be said to have fulfilled their choice. He was able, active, and enlightened, but he was unfortunately a visionary rather than a man of affairs or sound judgment. Instead of reducing chaos to order and concentrating his attention, as Brand had done so wisely in the Free State, on establishing security and promoting industry in the country, he took up, with all its entanglements, the old misguided policy of intrigues with native chiefs beyond the border and the dream of indefinite expansion. Thus he had no sooner taken office than he endeavoured to support the claims of Moshette against Montsioa as paramount chief of Bechuanaland, and having failed in bringing about this change, he made overtures to Montsioa in the following year to induce him to alter the Barolong boundary as settled by the Keate award. In this endeavour he was equally unsuccessful, and Montsioa, fearing further aggression, made a formal request to be taken under British protection (see BECHUANALAND). In 1875 Burgers proceeded to Europe with the project of raising a loan for the construction of a railway to Delagoa Bay. He was empowered by the Volksraad to raise £300,000, but with great difficulty he obtained in Holland the sum of £90,000 only, and that at a high rate of interest. With this inadequate sum some railway plant was obtained, and subsequently lay for ten years at Delagoa Bay, the scheme having to be abandoned for want of funds. On his return to the Transvaal in 1876 Burgers found that the condition of affairs in the state was worse than ever. The acting President had in his absence been granted leave by the Volksraad to carry out various measures opposed to the public welfare; native lands had been indiscriminately allotted to adventurers, and a war with Secocoeni, a native chief on the eastern borders of the country, was imminent. A commando was called out, which the President himself led. The expedition was an ignominious failure, and many burghers did not hesitate to assign their non-success to the fact that Burgers' views on religious questions were not sound. Burgers then proceeded to levy taxes, which were never paid; to enrol troops, which never marched; and to continue the head of a Government which had neither resources, credit, nor power of administration. In 1877 the Transvaal one-pound notes were valued at one shilling cash. Add to this condition of things the fact that the Zulus were threatening the Transvaal on its western border, and the picture of utter collapse which existed in the state is complete. In 1877 the condition of the Transvaal appeared so menacing to the peace of South Africa that Sir Theophilus Shepstone was despatched to the country by the High Commissioner, Sir Henry Barkly, to confer with President Burgers as to its future government. By this time Burgers had had his eyes opened to the true state of things. He was no longer blinded by the foolish optimism of a visionary who had woven fine-spun theories of what an ideal republic might be. He had lived among the Boers and attempted to lead their Government. He had found their idea of liberty to be anarchy, their native policy to be slavery, and their republic to be a sham. His was a bitter awakening, and the bitterness of it found expression in some remarkable words addressed to the Volksraad: "I would rather," said Burgers in March 1877, "be a policeman under a strong Government than the President of such a state. It is you—you members of the Raad and the Boers—who have lost the country, who have sold your independence for a drink. You have ill-treated the natives, you have shot them down, you have sold them into slavery, and now you have to pay the penalty. . . . We should delude ourselves by entertaining the hope that matters would mend by-and-by. . . . Do you know what recently happened in Turkey? Because no civilized government was carried on there, the Great Powers interfered and said, 'Thus far and no farther.' And if this is done to an empire, will a little republic be excused when it misbehaves? . . . If we want justice, we must be in a position to ask it with unsullied hands. . . . To-day a bill for £1000 was laid before me for signature, but I would sooner have cut off my right hand than sign that paper, for I have not the slightest ground to expect that when that bill becomes due there will be a penny to pay it with."

After spending some months at Pretoria, Shepstone satisfied himself that annexation was the only possible salvation for the Transvaal. The treasury was empty, the Boers refused to pay their taxes, and there was no power to enforce them. A public debt of £215,000 existed, and

Government contractors were left unpaid. Out of a male population of less than 9000, 3000 had already signed a petition for annexation. Sir Theophilus Shepstone therefore, in April 1877, issued a proclamation annexing the country. The proclamation stated: "It is the wish of Her Most Gracious Majesty that it [the state] shall enjoy the fullest legislative privileges compatible with the circumstances of the country and the intelligence of its people." The wisdom of the step taken by Shepstone has been called in question. Unfortunately, for many years subsequently the matter was so surrounded with the sophistry of English party politics that it was difficult for Englishmen to form any impartial opinion. The history of the Transvaal is more complete and better understood to-day than it was in 1877, and no one who acquaints himself with the simple facts of the position will deny that Shepstone's task was an extremely difficult one, and that he acted with care and moderation. The best evidence in favour of the step is to be found in the publicly expressed views of the state's own President, Burgers, already quoted. Moreover, the menace of attack on the Zulu side was a pressing and serious one. Even before annexation had occurred, Shepstone felt the danger so acutely that he sent a message to Cetewayo, the Zulu chief, warning him that British annexation was about to be proclaimed and that invasion of the Transvaal would not be tolerated. To this warning Cetewayo, who, encouraged by the defeat of the Boers at Secocoeni's hands, had already gathered his warriors together, replied: "I thank my father Somtseu [Shepstone] for his message. I am glad that he has sent it, because the Dutch have tired me out, and I intended to fight with them . . . and to drive them over the Vaal." . . . A still further reason for Shepstone's annexation, given by Sir Bartle Frere, was that Burgers had already sought alliance with Continental Powers, and Shepstone had no reason to doubt that if Great Britain refused to interfere, Germany would intervene. The only military force at Shepstone's command at the time of annexation was twenty-five policemen, and it is quite certain that, apart from the attitude of President Burgers, which cannot be said to have been one of active opposition, a large number, probably a majority of the Boers, accepted the annexation with complacency. Burgers himself left the Transvaal a disappointed, heart-broken man, and a deathbed statement published some time after his decease throws a lurid light on the intrigues which arose both before and after annexation. He shows how, for purely personal ends, Mr Kruger allied himself with the British faction who were agitating for annexation, and in order to undermine him and endeavour to gain the Presidency, actually urged the Boers to pay no taxes. However this may be, Burgers was crushed, but as a consequence the British Government and not Mr Paul Kruger was, for a time at least, master of the Transvaal. In view of his attitude before annexation, it was not surprising that Mr Kruger should be one of the first men to agitate against it afterwards. The work of destruction had gone too far. The plot had miscarried. And so Kruger and Jorissen, by whom he was accompanied, were the first to approach Lord Carnarvon with an appeal for revocation of the proclamation. To this request Lord Carnarvon's reply was that the act of annexation was an irrevocable one. Unfortunately, the train of events in England favoured the intrigues of the party who were bent on getting the annexation cancelled. In 1878 Lord Carnarvon resigned, and there were other evidences of dissension in the British cabinet.

British annexation, 1877.

Mr Kruger, who since the annexation had held a salaried appointment under the British Government, again became one of a deputation to England. On this occasion Sir T. Shepstone not unnaturally determined to dispense with his further services as a Government servant, and terminated the engagement. In the beginning of 1879 Shepstone was recalled and Colonel Owen Lanyon, an entire stranger to the Boers and their language, was appointed his successor as administrator in the Transvaal. In the meantime, the Zulu forces which threatened the Transvaal had been turned against the British, and the disaster of Isandhlwana occurred. Rumours of British defeat soon reached the Transvaal, and encouraged the disaffected party to become still bolder in their agitation against British rule. Thus Sir Bartle Frere wrote at the time: "All accounts from Pretoria represent that the great body of the Boer population is still under the belief that the Zulus are more than a match for us, that our difficulties are more than we can surmount, and that the present is a favourable opportunity for demanding their independence." In April Frere visited Pretoria and conferred with the Boers. He assured them that they might look forward to complete self-government under the Crown, and at the same time urged them to sink political differences and join hands with the British against their common enemy, the Zulus. The Boers, however, continued to agitate for complete independence, and with the honourable exception of Piet Uys, a gallant Boer leader, and a small band of followers, who assisted Colonel Evelyn Wood at Hlobani, the Boers held entirely aloof from the conflict with the Zulus, a campaign which cost Great Britain many lives and £5,000,000 before the Zulu power was finally broken. In June Sir Garnet Wolseley went to South Africa as commander of the forces against the Zulus, and as High Commissioner "for a time," in place of Sir Bartle Frere, of the Transvaal and Natal. After the settlement of the Zulu question, Sir Garnet Wolseley proceeded to Pretoria and immediately organized an expedition against the old Transvaal enemy Secocoeni, who throughout the Zulu campaign had been acting under the advice of Cetewayo. Secocoeni's stronghold was captured and his forces disbanded.

Agitation for independence.

It will be seen from this review of the events following annexation that the first work accomplished, over and above establishing a solvent and responsible Government in the country, was the demolition by the British of the two native foes who for so long had harassed the Boers. In speaking, after the conclusion of the native wars, on the question of the revocation of the Act of annexation, Sir Garnet Wolseley assured the Boers at a public gathering that so long as the sun shone the British flag would fly at Pretoria. In May 1880 he returned to England. Meanwhile events in Great Britain had once more taken a turn which gave encouragement to the disaffected Boers. Already in November 1879 Gladstone had conducted his Midlothian campaign. In his speeches he denounced in the strongest terms the annexation which had been carried out by the Beaconsfield Government. Referring to Cyprus and the Transvaal, he went so far as to say, "If those acquisitions were as valuable as they are valueless, I would repudiate them, because they were obtained by means dishonourable to the character of our country." Expressions such as these were translated into Dutch and distributed among the Boers by some of their leaders, and it is impossible not to admit that they exercised a good deal of influence in fanning the agitation for retrocession already going on in the Transvaal. So keenly were the Midlothian speeches appreciated by the Boers that the Boer committee wrote a letter of thanks to Mr Gladstone, and expressed the hope that, should a change

Effect of Mr Gladstone's speeches in England.

in the Government of Great Britain occur, "the injustice done to the Transvaal might find redress." In April 1880 this change in the British Government did occur. Gladstone became Prime Minister, and shortly afterwards Frere was recalled. Could events be more auspicious for the party seeking retrocession? If words in the mouth of an ex-minister at election-time meant anything, retrocession could only be a matter of time. The loyalists, not only in the Transvaal, but throughout South Africa, were disheartened and disgusted. The retrocession party in the Transvaal redoubled their efforts and their appeals. They were not destined to meet with such immediate success as the British premier's speeches, delivered during the heat of an election, very naturally led them to anticipate. On being directly appealed to by Kruger and Joubert, Mr Gladstone replied that the liberty which they sought might be "most easily and promptly conceded to the Transvaal as a member of a South African Confederation." This was not at all what was wanted, and the agitation continued. Meanwhile in the Transvaal itself, concurrently with the change of Prime Minister and High Commissioner, the Administrator, Colonel Lanyon, began vigorously to enforce taxation among the Boers. Men who would not pay taxes to their own appointed governments, and who were daily expecting to be allowed to return to that condition of anarchy which they had come to regard as the normal order of things, were not likely to respond willingly to the tax-gatherer's demands. That many of them refused payment in the circumstances which existed was natural.

In November matters were brought to a head by Bezuidenhout's waggons being seized in respect of the non-payment of taxes, and promptly retaken from the sheriff by a party of Boers. Lanyon began to recognize that the position was becoming grave, and wired to Sir George Colley, the High Commissioner of South-East Africa, for military aid. This, however, was not immediately available, and the Boers in public meeting at Paardekraal resolved once more to proclaim the South African Republic, and in the meantime to appoint a triumvirate, consisting of Kruger, Pretorius, and Joubert, who were to act as a provisional government. Within three days of the Paardekraal meeting a letter was sent to the Administrator demanding the keys of the Government offices within forty-eight hours. Hostilities forthwith began, and then followed a series of the most disastrous skirmishes, the most contradictory and most vacillating changes of policy, which have ever embarrassed a military force or discredited a Government. No outbreak or rebellion ever occurred under more anomalous conditions. While the Administrator and High Commissioner were endeavouring to carry out with very inadequate resources the declared policy of the British Government and their own instructions, continual pressure was being put on the British Prime Minister, not only from the insurgent Boers, but from his own followers, to carry out the policy he had avowed while out of office, and to grant the retrocession of the country. But it was not until Great Britain was suffering from the humiliation of defeat that the Premier was convinced that the time for granting that retrocession had arrived. The first shots fired were outside Potchefstroom, which was then occupied by a small British garrison, who, aided by the loyal inhabitants of the town, successfully sustained a siege of the place until after the close of the war. On 29th December a small body of some 240 men, chiefly belonging to the 94th Regiment, while marching from Lydenburg to Pretoria, were surprised and cut up by the Boer forces. Half the men were killed and wounded, the other half, including some officers, were taken prisoners. Of the prisoners, Captains Elliott and Lambert were subsequently treacherously shot by the Boers while crossing a stream, after they had been released on parole. In the meantime Pretoria, Rustenburg, Lydenburg, and other smaller towns had been placed in a position of defence under the directions of Colonel Bellairs, who remained in command at Pretoria, the garrison consisting of a small number of troops and the loyal inhabitants. Sir George Colley, with about 1400 men, marched towards the Transvaal frontier, but before reaching it he found, on 24th January 1881, that the Boers had already invaded Natal and occupied Lang's Nek. He pitched his camp at Ingogo. Having been defeated at Lang's Nek, and suffered considerable loss in an engagement near Ingogo, Colley took a force to the top of Majuba, a mountain overlooking the Boer camp and the Nek. He went up during the night, and in the morning was attacked and overwhelmed by the Boers (February 27). Of the 554 men who constituted the British force on Majuba, 92 were killed and 134 wounded, Sir George Colley himself being amongst the slain.

Outbreak of war, 1880.

Majuba Hill, 1881.

Ten days previous to the disaster at Majuba, Sir Evelyn Wood had arrived at Newcastle with reinforcements. On Colley's death he assumed command, and on 6th March concluded an armistice with Joubert at Lang's Nek. Lord Kimberley then telegraphed offering an amnesty to the Boers. Gladstone announced in Parliament that an opportunity for a settlement of affairs in the Transvaal had arisen. On 6th March the terms of peace were arranged between the Boers and Sir Evelyn Wood. The most important of these terms were, that the Transvaal should have complete self-government under British suzerainty, and that a British Resident should be stationed at Pretoria. The treaty of peace practically conceded all that the Boers demanded, and was never regarded as anything else than surrender either by the Boers or the loyalists in South Africa. It had hardly been concluded when Sir Frederick Roberts arrived at the Cape with 10,000 troops, and after spending forty-eight hours there returned to England.

In the meantime, while the English general was making a treaty under the instructions of British ministers on the frontier, the beleaguered garrisons of Pretoria, Potchefstroom, and other smaller towns were stoutly and gallantly holding their own. The news of the surrender reached Pretoria through Boer sources, and when first received there was laughed at by the garrison and inhabitants as a Boer joke. When the bitter truth was at length realized, the British flag was dragged through the dust of Pretoria streets by outraged Englishmen. At Potchefstroom the garrison under Colonel Winsloe were hard pressed. During the siege a third of their number had been killed and wounded. The Boer commander, Cronje, was duly informed of the armistice by his leaders, but in spite of this knowledge continued the siege for ten days afterwards, until Winsloe and his little band were compelled to surrender. In May the terms of settlement already agreed upon were drawn up at Pretoria in the form of a convention and signed. The preamble to the Pretoria Convention of 1881 contained in brief but explicit terms the grant of self-government to the Boers, subject to British suzerainty. In later years, when the Boers desired to regard the whole of this convention (and not merely the articles) as cancelled by the London Convention of 1884, and with it the suzerainty which was only mentioned in the preamble, Mr Chamberlain pointed out that if the preamble to this instrument were considered cancelled,

Pretoria Convention.

so also would the grant of self-government be cancelled The Pretoria Convention contained thirty-three articles. The most important of these reserved to Her Majesty "the control of the external relations of the said State, including the conclusion of treaties and the conduct of diplomatic intercourse with foreign Powers," and the right to march troops through the Transvaal. The boundaries of the state were defined, and to them the Transvaal was strictly to adhere.

The retrocession of the Transvaal was a terrible blow to the loyalists. The Boers, on the other hand, found themselves in better plight than they had ever been before. Their native foes Cetewayo and Secocoeni had been crushed by British forces; their liabilities were consolidated into a debt to Great Britain, to be repaid at convenience and leisure—as a matter of fact, not even interest was paid for some time. If ever a small state was well treated by a large one, the Transvaal was so in the retrocession of 1881. Unfortunately, this magnanimity was forthcoming after defeat. It appeared as though a virtue had been made of a necessity, and the Boers never could regard it in any other light.

The new régime.

The new Volksraad had scarcely been returned, and Mr Kruger elected President, before a system of Government concessions to private individuals was started. These concessions, in so far as they prejudiced the commerce and general interests of the inhabitants, consisted chiefly in the granting of monopolies. Among the first monopolies which were granted in 1882 was one for the manufacture of spirituous liquor. The system continued steadily down to 1899, by which time railways, dynamite, spirits, iron, sugar, wool, bricks, jam, paper, and a number of other things were all of them articles of monopoly. In 1882 also began that alteration of the franchise law which subsequently developed into positive exclusion of all but the original Boer burghers of the country from the franchise. In 1881, on the retrocession, full franchise rights could be obtained after two years' residence; in 1882 the period of residence was increased to five years. Meanwhile the land-hunger of the Boers became stimulated rather than checked by the regaining of the independence of their country. On the western border intrigues were already going on with petty tribal chiefs, and the Boers drove out a portion of the Barolongs from their lands, setting up the so-called republics of Stellaland and Goshen (see BECHUANALAND). This act called forth a protest from Lord Derby, the minister chiefly responsible for the Pretoria Convention, stating that he could not recognize the right of Boer freebooters to set up governments of their own on the Transvaal borders. This protest, however, had no effect upon the freebooters, who issued one proclamation after another until in November 1883 they united the two new republics under the title of the "United States of Stellaland." Simultaneously with this "irresponsible" movement for expansion, President Kruger, having found the policy of putting pressure upon Great Britain so successful, proceeded to London to interview Lord Derby and endeavour to induce him to dispense with the suzerainty, and to withdraw other clauses in the Pretoria Convention on foreign relations and natives, which were objectionable from the Boer point of view. Moreover, Kruger significantly requested that the term "South African Republic" should be substituted for Transvaal State.

The result was the London Convention of 1884. In this document a fresh set of articles was substituted for those of the Pretoria Convention of 1881. In the articles of the new convention the boundaries were once more defined, and to them the Transvaal was bound "strictly to adhere." In what followed it must always be remembered that Lord Derby began by emphatically rejecting the first Boer draft of a treaty on the ground that no treaty was possible except between equal sovereign states. Moreover, it is undeniable that Lord Derby acted as though he was anxious to appear to be giving the Boers what they wanted. He would not formally abolish the suzerainty, but he was willing not to mention it; and though, as before stated, in substituting new articles for those of the Pretoria Convention he left the preamble untouched, he avoided anything which could commit the Boer delegates to a formal recognition of that fact. On the other hand, he was most indignant when in the House of Lords he was accused by Lord Cairns of impairing British interests and relinquishing the Queen's suzerainty. He declared that he had preserved the thing in its substance, if he had not actually used the word; and this view of the matter was always officially maintained in the Colonial Office (which, significantly enough, dealt with Transvaal affairs) whatever the political party in power. Unfortunately, the timid way in which it was done made as ineffaceable an impression on Mr Kruger even as the surrender after Majuba. Article 4 stated: "The South African Republic will conclude no treaty or engagement with any state or nation other than the Orange Free State, nor with any native tribe to the eastward or westward of the Republic, until the same has been approved by Her Majesty the Queen." The other article to which the greatest interest was subsequently attached was Article 14:—"All persons, other than natives, conforming themselves to the laws of the South African Republic (*a*) will have full liberty, with their families, to enter, travel, or reside in any part of the South African Republic; (*b*) they will be entitled to hire or possess houses, manufactories, warehouses, shops, and premises; (*c*) they may carry on their commerce either in person or by any agents whom they may think fit to employ; (*d*) they will not be subject, in respect of their persons or property, or in respect of their commerce or industry, to any taxes, whether general or local, other than those which are or may be imposed upon citizens of the said Republic."

London Convention, 1884.

As the freebooters continued their operations in Bechuanaland, Sir Hercules Robinson despatched the Rev. J. Mackenzie to adjust matters and if necessary "to order the ejectment of the persons now trespassing at Rooi Grond" (see BECHUANALAND). Mr Mackenzie met with but partial success, and Mr Rhodes was sent to succeed him, but the latter equally failed to bring about a settlement. Meanwhile President Kruger "provisionally" proclaimed and ordained, "in the interests of humanity," that the territory in dispute should be under the protection of the South African Republic. Public protests were made in Cape Town and throughout the Colony against this last act of aggression, and in October 1884 Sir Charles Warren was despatched by the British Government to "pacificate" and "hold the country" pending further instructions. Thereupon President Kruger withdrew his proclamation, and on Sir Charles Warren's arrival met him and endeavoured to persuade him from proceeding. Sir Charles Warren subsequently broke up the freebooters' two states, and occupied the country without a shot being fired. The expedition cost Great Britain a million and a half, but the attempt at farther extension westwards was foiled. At the eastern border a similar policy was followed by the Boers, and in this instance with more success. Following up the downfall of the Zulu power after the British conquest in 1879, several parties of Boers began intriguing with the petty

Bechuanaland expedition.

chiefs, and in January 1883, in the presence of 10,000 Zulus, they proclaimed Dinizulu, the son of Cetewayo, to be king of Zululand (see ZULULAND). As a "reward" for their services to the Zulus, the Boers then took over from them a tract of country in which they established a "New Republic." Encouraged by success, the Boer claims were extended until at the end of 1885 they claimed about three-fourths of the whole Zulu territory. In 1886 the "New Republic," with limits considerably narrowed, was recognized by Great Britain, and the territory became incorporated with the Transvaal in 1888. Their eastern boundary, in the teeth of the spirit of the conventions, and with but scant observance of the letter, was by this means eventually considerably extended. A similar policy eventually brought Swaziland almost entirely under their dominion (see SWAZILAND).

Meanwhile, events occurring within the state augured ill for the future of the country. In 1884 a concession to a number of Hollander and German capitalists of all rights to make railways in the state led to the formation of the Netherlands Railway Company. This company, which was not actually floated till 1887, was destined to exercise a disastrous influence upon the fortunes of the state. Gold digging, which had commenced with the discovery in 1869 of the Zoutpansberg and Lydenburg gold-fields, had hitherto enjoyed in the Transvaal but a precarious existence. In 1883 the discovery of Moodie's Reef near the Kaap Valley led to a considerable influx of diggers and prospectors from the colonies and Europe, and by 1884 the Sheba Mine had been opened up and Barberton, with a population of 5000 inhabitants, sprung into existence. In 1886 the Rand gold-fields, which had just been discovered, were proclaimed and Johannesburg was founded. From that time the gold industry made steady progress until the Rand gold mines proved the richest and most productive gold-field in the world. As the industry prospered, so did the European population increase. The revenue of the state went up by leaps and bounds. In 1882 it was £177,407; in 1889, £1,577,445; in 1896, £3,912,095. At the end of 1886 Johannesburg consisted of a few stores and some few thousand inhabitants. In October 1896 the Sanitary Board census estimated the population as 107,078, of whom 50,907 were Europeans. The wealth which was pouring into the Boer state coffers exceeded the wildest dreams of President Kruger and his followers. Land went up in value, and farms, many of them at comparatively remote distances from the actual gold-fields, were sold at enormously enhanced prices. In fact, so attractive did this sale of land become to the Boers that they eventually parted with a third of the whole land area of the country to Uitlander purchasers. Yet in spite of the wealth which the industry of the Uitlanders was bringing both to the state and to individuals, a policy of rigid political exclusion and restriction was adopted towards them.

Economic developments: Gold industry.

An attempt was made in 1888, after the conference held between Cape Colony, the Orange Free State, and Natal, to induce the Transvaal to enter the Customs Union. Kruger would have none of it. His design at this time was ultimately to bring the whole of the external trade of the state, which was growing yearly as the gold industry developed, through Delagoa Bay and over the Netherlands Railway (see ORANGE RIVER COLONY and CAPE COLONY). His hostility towards Great Britain and even Cape Colony led him to adopt a commercial policy both narrow and prejudicial to the interests of the gold industry. In 1888 Sir John Brand, President of the Free State, who had always been an enlightened advocate of civilization and friendly relations with Great Britain, died. He was succeeded in 1889 by Mr Reitz. In the appointment of Mr Reitz, President Kruger recognized a new opportunity of endeavouring to cajole the Free State. While Brand was alive he had arranged, in the teeth of the strongest protests from Mr Kruger, that the Cape railway should extend to Bloemfontein and subsequently to the Vaal river. President Kruger now endeavoured to bind the future railway policy of the Free State, and induced the Free State to agree to a treaty whereby each state bound itself to help the other whenever the independence of either should be threatened or assailed, unless the cause of quarrel was, in the eyes of the state called in to assist, an unjust one. This was the thin end of the wedge, which in Brand's time President Kruger had never been able to insert into the affairs of the Free State.

Relations with the rest of South Africa.

President Kruger now turned his attention to finding a seaport, and was only prevented from doing so by the British annexation of Tongaland, which barred his progress in that direction. In 1890 a feeling of considerable irritation had grown up among the Uitlanders at the various monopolies, but particularly at the dynamite monopoly, which pressed solely and with peculiar severity upon gold-miners. Requests for some consideration in the matter of the franchise, and also for a more liberal commercial policy in the matter of railways, dynamite and customs dues, began to be made. In response Kruger resorted to the most sweeping alteration in the franchise law. He enacted that the period of qualification for the full franchise should now be raised to ten years instead of five. He at the same time instituted what was called a second chamber, the franchise qualifications for which were certainly less, but which was not endowed with any real power. During this year Kruger visited Johannesburg, and what was known as "the flag incident" occurred. He had by this time rendered himself somewhat unpopular, and in the evening the Transvaal flag, which flew over the landdrost's house, was pulled down. This incensed Kruger so much that for many years he continued to quote it as a reason why no consideration could be granted to the Uitlanders.

Oligarchical restrictions.

In 1891 the Transvaal attempted its last border raid before the war of 1899. The Banjailand trek was organized. The trekkers intended forcibly to annex a portion of the British South Africa Company's territory. The High Commissioner protested, and the President prohibited the trek, but the trekkers were not finally turned back until they were opposed by the British South Africa forces under Dr Jameson and Colonel Goold-Adams.

In 1892 the Uitlanders began to feel that if they were to obtain any redress for their grievances some combined constitutional action was called for, and the first reform movement began. The Transvaal National Union was formed. This consisted at the outset chiefly of mercantile and professional men and artisans. The mining men, especially the heads of the larger houses, did not care at this juncture to run the risk of political agitation. The Hon. J. Tudhope, an ex-minister in the Cape Government, was elected chairman of the Union. The objects of this body were avowed from the outset. They desired equal rights for all citizens in the state, the abolition of monopolies and abuses, together with the maintenance of the state's independence. In the furthering of this policy the Uitlander leader, Mr Tudhope, was supported by Mr Charles Leonard and his brother Mr James Leonard, who at one time had distinguished himself as attorney-general of Cape Colony.

Uitlander grievances.

Both the Leonards, as well as many of their followers, were South Africans by birth. They, in common with the great bulk of the Uitlanders, recognized that the state had acquired its independence, and had every right to have that independence respected. They neither sought nor desired to see it abolished. But they asserted that a narrow and retrogressive policy, such as Kruger was following, was the very thing to endanger that independence. The soundness of these views and the legitimacy of Uitlander aspirations were recognized by a few of the most enlightened men among the Boer officials at Pretoria. Some prominent burghers even spoke at Uitlander meetings in favour of the Uitlander requests. At a later date, Chief Justice Kotze when on circuit warned the Boers that in its retrogressive action the Boer Government was undermining the *grondwet* or constitution of the state. It soon became evident that one course, and one only, lay open to President Kruger if he desired to avert a catastrophe. It was to meet in a friendly spirit those men who had by their industry converted a poor pastoral country into a rich industrial one, who represented more than half the inhabitants, who paid more than three-fourths of the revenue, and who were anxious to join him as citizens, with the rights of citizenship. He chose a course diametrically opposite. In an interview accorded to seven delegates from the National Union, who visited him in 1892, with regard to reforms, he told Mr Charles Leonard to "go back and tell your people that I shall never give them anything. I shall never change my policy. And now let the storm burst." In 1894 there occurred an incident which not only incensed the Uitlanders to fury, but called for British intervention. A number of British subjects resident in the Transvaal, in spite of their having no political status, were commandeered for compulsory service to suppress a native rising. This led to a protest, and eventually a visit to Pretoria, from Sir Henry Loch. In the negotiations between Sir Henry Loch and President Kruger which followed, President Kruger at length agreed to extend "most favoured nation" privileges to British subjects in reference to compulsory military service, and five British subjects who had been sent as prisoners to the front were released. This result was not, however, achieved before President Kruger had done his utmost to induce Sir Henry Loch to promise some revision in favour of the Transvaal of the London Convention. Following this incident came a further alteration in the franchise law, making the franchise practically impossible to obtain. At a banquet given in honour of the German Emperor's birthday in Pretoria in January 1895, Kruger referred in glowing terms to the friendship of Germany for the Transvaal, which in the future was to be more firmly established than ever. This speech was public evidence of what was known to be going on behind the scenes. The German consul at Pretoria at this juncture was a volatile, sanguine man, with visionary ideas of the important part Germany was to play in the future as the patron and ally of the South African Republic, and of the extent to which the Bismarckian policy might go in abetting an anti-British campaign. Whether he deceived himself or not, he led President Kruger and the Boers to believe that the Kaiser was prepared to go to almost any length in support of the Transvaal if an opportunity occurred. His influence was an undoubted factor in the Kruger policy of that time.

Commandeering incident.

German flirtation.

A minor incident early in 1895 served to mark the truculent attitude which the Boer Government had come to adopt towards the Uitlander population at Johannesburg. The Netherlands Railway had at length, very late in the day, completed their line from the Delagoa Portuguese frontier to Pretoria. To the official banquet in honour of the event invitations were issued to the High Commissioner and a host of minor Government officials in Pretoria. To the large commercial and mining houses in Johannesburg, to the men who had built up that very commerce which the new railway was built to carry, no invitations were sent. The Uitlanders were ignored. The Delagoa Bay Railway now being completed, Kruger determined to take steps to bring the Rand traffic over it. The Netherlands Railway began by putting a prohibitive tariff on goods from the Vaal river (see CAPE COLONY). Not to be coerced in this manner, the Rand merchants proceeded to bring their goods on from the Vaal by waggon. Kruger then closed the drifts (or fords) on the river by which the waggons crossed. He only reopened them after the receipt of what was tantamount to an ultimatum on the subject from Great Britain.

Drifts incident.

At this time the Uitlanders formed a majority of the population, owned half the land and nine-tenths of the property, and they were at least entitled to a hearing. When in August they forwarded one of their many petitions praying for redress of their grievances and an extension of the franchise, their petition with over thirty-five thousand signatures was rejected with jeers and insult. One member of the Raad, during a debate in the Chamber, called upon the Uitlanders to "come on and fight" for their rights if they wanted them. The words, it is true, were but the utterance of an individual Raad member, but they were only a shade less offensive than those used by President Kruger in 1892, and they too accurately described the attitude of the Boer executive. In September a combined meeting of the Chambers of Mines and Commerce was held at Johannesburg, and a letter on various matters of the greatest importance to the mining industry and community at Johannesburg was addressed to the Boer executive. It was never vouchsafed an answer. Men of any spirit among the Uitlanders were exasperated beyond measure. Their position was not merely unjust; it was humiliating. What the next step should be was freely discussed. It was easy to propound the question, impossible to answer it. Some urged an appeal to the Imperial Government; but others, especially men of colonial birth and experience, objected that they would be leaning on a broken reed. That men who had still the memory of Majuba in their hearts should have felt misgiving is not to be wondered at. At this juncture came overtures to the leading Uitlanders from Mr Rhodes and Dr Jameson, leading to the Jameson Raid. To one or two men this scheme, subsequently known as the Jameson Plan, had been revealed earlier in the year, but to the majority even of the small group of leaders it was not known till October or November 1895. The proposition came in a tempting hour. Mr Rhodes and Dr Jameson, after considerable deliberation, came to the conclusion that they might advantageously intervene between Mr Kruger and the Uitlanders. They induced Mr Alfred Beit, who was an old personal friend of Mr Rhodes, and also largely interested in the Rand gold mines, to adopt this view and to lend his co-operation. They then submitted their scheme to some of the Uitlander leaders. Between them it was arranged that Dr Jameson should gather a force of eight hundred men on the Transvaal border; that the Uitlanders should continue their agitation; and that, should no satisfactory concession be obtained from President Kruger, a combined movement of armed forces should be made against the Government. The arsenal at Pretoria was to be seized; the Uitlanders in Johannesburg were to rise and hold the town. Jameson

Uitlander reform movement.

The "Jameson Plan."

was to make a rapid march to Johannesburg. The various movements were to be started simultaneously. Meanwhile, in order to give Mr Kruger a final chance of making concessions with a good grace, and for the purpose of stating the Uitlander case to the world, Mr Leonard, as chairman of the National Union, issued a historic manifesto, which concluded as follows :—

> We have now only two questions to consider: (*a*) What do we want? (*b*) How shall we get it? I have stated plainly what our grievances are, and I shall answer with equal directness the question, What do we want? We want: (1) the establishment of this Republic as a true Republic; (2) a *grondwet* or constitution which shall be framed by competent persons selected by representatives of the whole people and framed on lines laid down by them—a constitution which shall be safeguarded against hasty alteration; (3) an equitable franchise law, and fair representation; (4) equality of the Dutch and English languages; (5) responsibility to the heads of the great departments of the Legislature; (6) removal of religious disabilities; (7) independence of the courts of justice, with adequate and secured remuneration of the judges; (8) liberal and comprehensive education; (9) efficient Civil Service, with adequate provision for pay and pension; (10) free trade in South African products. That is what we want. There now remains the question which is to be put before you at the meeting of the 6th January, viz., How shall we get it? To this question I shall expect from you an answer in plain terms according to your deliberate judgment.

The Jameson conspiracy fared no worse and no better than the great majority of conspiracies in history. It failed in its immediate object. Dr Jameson did not obtain more than five hundred men. Johannesburg had the greatest difficulty in smuggling in and distributing the rifles with which the insurgents were to be armed. The scheme to seize the Pretoria fort had to be abandoned, as at the time fixed Pretoria was thronged with Boers. Finally, to make confusion worse confounded, Dr Jameson, becoming impatient of delay, in spite of receiving direct messages from the leaders at Johannesburg telling him on no account to move, marched into the Transvaal on the day which had been provisionally decided on.

The policy of delay in the execution of the plot which the Uitlander leaders found themselves compelled to adopt was determined by a variety of causes. Apart from the difficulty of obtaining arms, a serious question arose at the eleventh hour which filled some of the Uitlanders with mistrust. The reform leaders in the Transvaal, down to and including the Johannesburg rising, had always recognized as a cardinal principle the due observance and maintenance of the independence of the state. From Cape Town it was now hinted that the movement in which Dr Jameson was to co-operate should, in Mr Rhodes's view, be carried out under the British flag. A meeting of Uitlander leaders was hastily summoned on 25th December. Two messengers were that night despatched to interview Mr Rhodes, who then gave the assurance that he approved of the republican flag. Meanwhile, on 29th December, Dr Jameson had started, and the news of his having done so reached Johannesburg from outside sources. A number of leading citizens were at once formed into a reform committee. In the absence of Mr Charles Leonard, who had been sent as one of the delegates to Cape Town to interview Mr Rhodes, Mr Lionel Phillips, a partner in Messrs Eckstein & Co., the largest mining firm on the Rand, was elected chairman. Mr Phillips had been for three years in succession chairman of the Chamber of Mines, and he had persistently for several years endeavoured to induce President Kruger to take a reasonable view of the requirements of the industry. He was a man of marked ability and energy, and enjoyed the confidence of the great majority of the Uitlanders. Under the supervision of the reform committee, such arms as had been smuggled in were now distributed, and Colonel Frank Rhodes was given charge of the armed men. The canteens were closed in the towns and along the mines. A large body of police was enrolled, and order was maintained throughout the town. On 2nd January 1896 Dr Jameson, who found himself at Doornkop in a position surrounded by Boers, surrendered. Dr Jameson and his men were conveyed to Pretoria as prisoners, and subsequently handed over to the High Commissioner. The whole of the reform committee (with the exception of a few who fled the country) were arrested on a charge of high treason and imprisoned in Pretoria; they were then brought up for preliminary examination in the Raadzaal, and committed for trial. In April, at the trial, the four leaders—Mr Lionel Phillips, Colonel Frank Rhodes, Mr J. H. Hammond, and Mr George Farrar, who in conjunction with Mr Charles Leonard had made the arrangements with Dr Jameson—were sentenced to death, the sentence being after some months' imprisonment commuted to a fine of £25,000 each. The rest of the committee were each sentenced to two years' imprisonment, £2000 fine or another year's imprisonment, and three years' banishment. This sentence, after a month's incarceration, was also commuted. The fine was exacted, and the prisoners, with the exception of Woolls Sampson and Karri Davis, were liberated on undertaking to abstain from politics for three years in lieu of banishment. Messrs Sampson and Davis, refusing to appeal to the executive for a reconsideration of their sentence, were retained for over a year. At a later date both of them, as well as several of their reform colleagues, served gallantly in the Imperial Light Horse during the war.

Collapse of Jameson Raid and Johannesburg rising.

Sir Hercules Robinson was unfortunately in feeble health at the time, and having reached Pretoria on the 4th of January, he had to conduct negotiations under great physical disadvantage. He had no sooner learnt of the Raid in Cape Town than he issued a proclamation through Sir Jacobus de Wet, the British Resident at Pretoria, warning all British subjects in Johannesburg or elsewhere from aiding and abetting Jameson. This was freely distributed among the public of Johannesburg. While in Pretoria the High Commissioner in the first instance addressed himself to inducing Johannesburg to lay down its arms. He telegraphed to the reform committee that President Kruger had insisted "that Johannesburg must lay down arms unconditionally as a precedent to any discussions and consideration of grievances." On the following day, 7th January, Sir Hercules telegraphed again through the British Agent, who was then at Johannesburg, saying: "That if the Uitlanders do not comply with my request they will forfeit all claims to sympathy from Her Majesty's Government and from British subjects throughout the world, as the lives of Jameson and the prisoners are now practically in their hands." The two thousand odd rifles which had been distributed among the Uitlanders were then given up. With regard to the inducements to this step urged upon the reform committee by the High Commissioner, it is only necessary to say with reference to the first that the grievances never were considered, and with reference to the second it subsequently appeared that one of the conditions of the surrender of Dr Jameson's force at Doornkop was that the lives of the men should be spared. It was after the Johannesburg disarmament that President Kruger had sixty-four members of the reform committee arrested, announcing at the same time that his motto would be "Forget and forgive." Sir Hercules Robinson, in response to a message from the British Government urging him to use firm language in reference to reasonable concessions, replied that he considered the moment inopportune, and on 15th January he left for Cape Town.

In the three years which intervened between the Jameson

Raid and the outbreak of the war in 1899 Kruger's administration continued to be what it had been before the war; that is to say, it was not merely bad, but it got progressively worse. His conduct immediately after Johannesburg had given up its arms, and while the reform committee were in prison, was distinctly disingenuous. Instead of discussing grievances, as before the Johannesburg disarmament he had led the High Commissioner to believe was his intention, he proceeded to request the withdrawal of the London Convention, because, among other things, "it is injurious to dignity of independent Republic." When President Kruger found that no concession was to be wrung from the British Government, he proceeded, instead of considering grievances, to add considerably to their number. The Aliens' Expulsion and Aliens' Immigration Laws, as well as the new Press Law, were passed in the latter part of 1896.

After the Raid.

In 1897 a decision of Chief Justice Kotze was overruled by an Act of the Volksraad. This led to a strong protest from the judges of the High Court, and eventually led to the dismissal of the Chief Justice, who had held that office for over twenty years, and during the whole of that time had been a loyal and patriotic friend to his country. While in office Mr Kotze had protested that no honourable man could continue to sit as judge under such conditions. After dismissal he spoke out still more plainly at a public dinner in Johannesburg, and openly charged President Kruger with the tyranny of a despot. An Industrial Commission appointed during this year by President Kruger fared no better than the High Court had done. The commission was deputed to inquire into and report on certain of the grievances adversely affecting the gold industry. Its constitution for this purpose was anomalous, as it consisted almost entirely of Transvaal officials whose knowledge of the requirements of the industry was scanty. In spite of this fact, however, the commission reported in favour of reform in various directions. They urged, among other things, due enforcement of the liquor law, more police protection, the abolition of the dynamite concession, and that foodstuffs should be duty free. These recommendations made by President Kruger's own nominees were practically ignored. In January 1899 the British Colonial Secretary, Mr Chamberlain, pointed out in a despatch to President Kruger that the dynamite monopoly constituted a breach of the London Convention. In order to help the Transvaal Government out of its difficulty, and to make one more effort towards conciliation, the financial houses of Johannesburg offered to lend the Transvaal Government £600,000 wherewith to buy out the dynamite company, and so terminate the scandal and bring some relief to the industry. The offer was not accepted. In May the Uitlanders, hopeless of ever obtaining redress from President Kruger, weary of sending petitions to the Raad only to be jeered at, determined to invoke intervention if nothing else could avail, and forwarded a petition to Queen Victoria. This petition, the outcome of the second Uitlander movement for reform, was signed by 21,000 British subjects, and stated the Uitlander position at considerable length. The following extract conveys its general tenor :—

Petition to the Queen.

"The condition of your Majesty's subjects in this State has become well-nigh intolerable. The acknowledged and admitted grievances, of which your Majesty's subjects complained prior to 1895, not only are not redressed, but exist to-day in an aggravated form. They are still deprived of all political rights, they are denied any voice in the government of the country, they are taxed far above the requirements of the country, the revenue of which is misapplied and devoted to objects which keep alive a continuous and well-founded feeling of irritation, without in any way advancing the general interest of the State. Maladministration and peculation of public moneys go hand in hand, without any vigorous measures being adopted to put a stop to the scandal. The education of Uitlander children is made subject to impossible conditions. The police afford no adequate protection to the lives and property of the inhabitants of Johannesburg; they are rather a source of danger to the peace and safety of the Uitlander population."

In response to this appeal, which the Imperial Government felt themselves bound to deal with, Mr Chamberlain proposed a conference; and this was arranged between President Kruger and Sir Alfred Milner, who met at Bloemfontein on 31st May 1899. It no sooner opened than it was evident that Kruger had come to obtain, not to grant, concessions. He offered, it is true, a seven years' franchise law in place of the five years' franchise which Sir Alfred Milner asked for. But apart from the relief suggested being entirely inadequate, it was only to be given on certain conditions, one of which was that all future disputes which might arise between the Transvaal and the Imperial Government should be referred to a court of arbitration, of which the president should be a foreigner. No arrangement was possible on such terms. Meanwhile feeling was running high at Johannesburg and throughout South Africa. Meetings were held in all the large towns, at which resolutions were passed declaring that no solution of the Transvaal question would be acceptable which did not provide for equal political rights for all white men. Sir Alfred Milner (who in a published despatch compared the position of the Uitlanders to that of "helots") urged the Home Government strongly to insist upon a minimum of reform, and primarily the five years' franchise; and Mr Chamberlain, backed by the Cabinet, adopted the policy of the High Commissioner. (A. P. H.)

Bloemfontein conference.

The Crisis of 1899.

A state of extreme diplomatic tension lasted all the summer. The British public, in whom there had always been the latent desire to wipe out the memory of Majuba, were at last awakened by the Ministerialist press to the necessity of vindicating British influence in South Africa, and the Government soon found that, in spite of a highly articulate Radical minority, the feeling of the country was overwhelmingly behind them. It was not then realized either by the public or the Government how seriously, and with what considerable justification, the Boers believed in their ability, if necessary, to sweep the English "into the sea." President Kruger had every expectation of large reinforcements from the Dutch in the two British colonies; he believed that, whatever happened, Europe would not allow Boer independence to be destroyed; and he had assured himself of the adhesion of the Orange Free State, though it was not till the very last moment that President Steyn formally notified Sir Alfred Milner of this fact. The Boers profoundly despised the military power of Great Britain, and there was no reason why they, any more than Germany or France, should contemplate the possibility of the Empire standing together as a whole in such a cause. In England, on the other hand, it was thought by most people that if a firm enough attitude were adopted Mr Kruger would "climb down," and the effect of this error was shown partly in the whole course of the negotiations, partly in the tone personally adopted by Mr Chamberlain. It was only later that it was seen that if Great Britain intended effectually to champion the Uitlander cause, the moment for a test of strength had inevitably arrived. Negotiations could only bring the conflict a little nearer, delay it a little longer, or supply an opportunity to either side to justify its action in the

eyes of the world. The conditions of the problem were such that unless Great Britain were to accept a humiliating rebuff, any correspondence, however skilfully conducted, was bound to bring into greater prominence the standing causes of offence between the two sides. The exchange of despatches soon led to a complete *impasse*. The persistent attempt of the South African Republic to assert its full independence, culminating in a formal denial of British suzerainty, made it additionally incumbent on Great Britain to carry its point as to the Uitlander grievances, while, from Mr Kruger's point of view, the admission of the Uitlanders to real political rights meant the doom of his oligarchical régime, and appeared in the light of a direct menace to Boer supremacy. The franchise, again, was an internal affair, in which the Convention gave Great Britain no right to interfere, while if Great Britain relied on certain definite breaches of the Convention, satisfaction for which was sought in the first place in such a guarantee of amendment as the Uitlander franchise would involve, the Boer answer was an offer of arbitration, a course which Great Britain could not accept without admitting the South African Republic to the position of an equal. Here was material enough for an explosion, even if personal misunderstandings and aggravations, adding fuel to the fire, had not naturally occurred (or even been deliberately plotted) during the negotiations. But the truth was that the Boers thought they stood to gain by fighting, while the British, though not expecting war, and acting up till the last month or so on the assumption that serious military preparations were either unnecessary or sufficiently unlikely to be necessary to make them politically inexpedient, had with no less confidence committed themselves to a policy which was impracticable on peaceful terms.

After July the tactics of the Boer executive were simply directed towards putting off a crisis till the beginning of October, when the grass would be growing on the veldt, and meanwhile towards doing all they could in their despatches to put the blame on Great Britain. At last they drafted on 27th September an ultimatum to the British Government. But, although ready drafted, many circumstances conspired to delay its presentation. Meanwhile, the British War Office began to wake up. Certain departmental details were despatched to South Africa to form a working nucleus for military bases, and early in September the Cabinet sanctioned the despatch to Natal from India of a mixed force, 5600 strong, while two battalions were ordered to South Africa from the Mediterranean. Sir George White was nominated to the chief command of the forces in Natal, and sailed on 16th September, while active preparations were set on foot in England to prepare against the necessity of despatching an army corps to Cape Town, in which case the chief command was to be vested in Sir Redvers Buller. Fortunately, although the draft of the ultimatum was lying in the State Secretary's office in Pretoria, the Boers, unprepared in departmental arrangements which are necessary in large military operations, were unable to take the field with the promptitude that the situation demanded. They consequently forfeited many of the advantages of the initiative. Thus it happened that, while the ultimatum remained undelivered in Pretoria, the British Government were able, if not to render their line of resistance secure, at least to prop it with sufficient reinforcements to enable it to defeat the crowning object of the Boer invasion of Natal—the capture of Pietermaritzburg and Durban.

The military strength of the two republics was practically an unknown quantity. It was certain that, since the troublous times of 1896, the Transvaal had greatly increased its armaments; but at their best, except by a very few, the Boers were looked upon by English military experts as a disorganized rabble, which, while containing many individual first-class marksmen, would be incapable of maintaining a prolonged resistance against a disciplined army. As was to be subsequently shown, the hostilities were not confined to opposition from the fighting strength of the two little republics alone; the British had to face Dutch opposition in their own colonies, and it was only the apathy and caution of the South African Dutch, taken as a whole, which saved the Empire from disaster. The total fighting strength of the Boer republics was probably never more than 60,000 men, and of these it is doubtful if at any period of the war there were more than 36,000 in the field at the same time. But the fact that it was to a large extent a struggle with a nation in arms doubled the numbers of the force that the Transvaal executive was able to draw upon, while to this may be added the not insignificant total of 10,000 Uitlanders and foreigners, and 15,000 Kaffirs, employed in menial duties attendant upon military operations. Of this force only a microscopic proportion was permanent and disciplined. At the outbreak of war the disciplined forces in the Transvaal were the South African Republic Police, about 1400 strong, with 20 officers; the Swaziland Police, 400 strong; and the Staats Artillerie, which, when the reservists were called up in mobilization for war, numbered about 800 men. The permanent forces of the Orange Free State simply consisted of an artillery corps, at the most 400 strong. For the rest, the bulk of the Dutch levies were organized on the burgher system—that is, each district was furnished with a commandant, who had under him field-cornets and assistant field-cornets, who administered the fighting capacity of the district. Each field-cornet, who, with the commandant, was a paid official of the state, was responsible for the arms, equipment, and attendance of his commando—the commando being the tactical as well as the administrative unit; any number of commandoes might be grouped under one commandant. Vecht, or fighting generals, again, exercised an authority above the commandants, while the supreme military control was vested in the Commandant-General.

The plan of campaign which found favour with the Boers, when they determined to put their differences with Great Britain to the test by the ordeal of the sword, was to attack all the principal British towns adjacent to their own borders; at the same time to despatch a field army of the necessary dimensions to invade and reduce Natal, where the largest British garrison existed. It is not too much to suppose that the executive in Pretoria had calculated that the occupation of Durban would inspire the entire Dutch nation with a spirit of unanimity which would eventually wrest South Africa from the British. On paper the scheme had everything to recommend it, as the expedient most likely to bring about the desired end. But the departmental executive could not push off the Natal invading force as early as had been anticipated, and it was not until 9th October that the ultimatum was presented to Mr Cunyngham Green, the British agent at Pretoria. This ultimatum proved to be an arrogant document, in which the situation was reviewed in a manner which showed clearly that the Boer Government had determined long before to put their differences to the final test of arms, and that the later negotiations had but served to cover the warlike preparations which were in hand. The scheduled demands were as follows:—

"(*a*) That all points of mutual difference shall be

regulated by the friendly course of arbitration, or by whatever amicable way may be agreed upon by the Government with Her Majesty's Government.

"(*b*) That the troops on the borders of this Republic shall be instantly withdrawn.

The ultimatum.

"(*c*) That all reinforcements of troops which have arrived in South Africa since the 1st of June 1899 shall be removed from South Africa within a reasonable time, to be agreed upon with this Government, and with a mutual assurance and guarantee on the part of this Government that no attack upon or hostilities against any portion of the possessions of the British Government shall be made by the Republic during further negotiations within a period of time to be subsequently agreed upon between the Governments, and this Government will, on compliance therewith, be prepared to withdraw the armed burghers of this Republic from the borders.

"(*d*) That Her Majesty's troops now on the high seas shall not be landed in any part of South Africa."

To these demands the Transvaal Government required an answer within 48 hours.

There could be only one reply, and on Wednesday, 11th October 1899, at five o'clock P.M., a state of war existed between the British Government and the two Boer republics. On the following day the Boer attack on an armoured train at Kraaipan, on the western frontier of the Transvaal, witnessed the first hostile shot of a bloody war, destined to plunge South Africa into strife for two years and a half.

The War of 1899–1902.

For the purposes of history the South African campaign may be conveniently divided into five distinct periods. The first of these would be the successful Boer invasion of British territory, terminating with the relief of Ladysmith on 28th February; the second, the period of Boer organized resistance, which may be said to have finished with Lord Roberts's formal annexation of the Transvaal on 25th October 1900, and the flight of ex-President Kruger to Holland. The next period, the most unsatisfactory of the whole war, may be characterized as a period of transition; it marks the opening of earnest guerilla resistance on the part of the enemy, and uncertain casting about on the part of the British for a definite system with which to grapple with an unforeseen development. This phase may rightly be said to have continued until the abortive Middelburg negotiations were broken off on 16th March 1901. The next stage was that which saw the slow building up of the blockhouse system and the institution of small punitive columns, and may be considered to have extended until the close of 1901. The fifth, and last, period—which, after all other expedients had failed, finally brought the residue of uncaptured and unsurrendered burghers to submission—was the final development of the blockhouse system, wedded to the institution of systematic "driving" of given areas, which operations were in force until 31st May 1902, the date upon which a peace was ratified at Pretoria between Lord Kitchener and the representative Boer leaders.

Stages of the war.

The first of these periods saw the severest fighting of the campaign. It opened with the investment of Mafeking by a Transvaal force under P. A. Cronje, the envelopment of Kimberley by Free State commandoes under General Wessels, and on 1st November the complete isolation of the bulk of the Natal Field Force in Ladysmith by the main Federal army under Commandant-General Piet Joubert. The Natal Field Force, however, did not submit to investment without a struggle; and before the enemy finally cut the communication with the south, portions of Sir George White's force had fought four considerable actions with the invading army. The first two of these were of the nature of British successes. On 20th October the detached brigade at Talana drove back the Boer left under Lucas Meyer. But this superiority was bought at a price which nullified many of the results of victory. General Sir W. Penn Symons, the British officer in command, was mortally wounded, and after losing half its mounted men as prisoners and 226 officers and men killed and wounded, the brigade only escaped being enveloped by beating a masterly retreat upon Ladysmith, where it arrived in a very exhausted state on 26th October. In the meantime Sir George White had taken the aggressive, and hearing on 20th October that an advance guard under General Kock had occupied Elandslaagte, and placed itself athwart the direct communications of General Symons's force, he detached a force of all arms under Major-General French, and defeated Kock after a sanguinary engagement on 21st October (British losses, 258 all ranks killed and wounded). Three days later Sir George White fought a second engagement against the enemy advancing from the north at Tintwa Inyoni, in order to cover the retirement of the Dundee force. It was an inconsequent action, which cost the Natal Field Force 118 casualties, the majority of which occurred in the Gloucestershire Regiment. By 29th October Joubert's army had practically enveloped Ladysmith, and Sir George White determined to strike a blow in force which should be decisive in effect. The result of this decision was the battle of Lombard's Kop, outside Ladysmith, in which the whole of Sir George White's available garrison was engaged. The engagement was disastrous to the British, who had undertaken far too comprehensive an attack, and the Natal Field Force was obliged to fall back upon Ladysmith, with the loss of 1500 men in casualties, including the headquarters of the Gloucestershire and Royal Irish Fusiliers, which surrendered to the Free Staters and Johannesburg zarps at Nicholson's Nek. From that day the rôle of the Natal Field Force was changed from that of a hostile field army into the defence of a standard on a hill, and two days later it was completely isolated, but not before General French had succeeded in escaping south by train, and the naval authorities had been induced by Sir George White's urgent appeals to send into the town a Naval Brigade with a few guns of sufficient range and calibre to cope with the heavy position artillery which Joubert was now able to bring into action against the town.

Sir George White's operations in Natal.

The Ladysmith "entanglement."

General Sir Redvers Buller, who had been given the supreme command in South Africa as soon as it was perceived that war was the only solution to the South African trouble—his force being an army corps in three divisions, the divisional generals being Lord Methuen, Sir W. Gatacre, and Sir W. Clery—arrived in Cape Town, ahead of his troops, on the day following the final bid of Sir George White's army. The situation which presented itself was delicate in the extreme. In Natal practically the whole of the available defence force was swallowed up by the steady success of the invasion; on the western frontier two important British towns were isolated and besieged; and Federal commandoes were on the point of invading Cape Colony, which, as far as its Dutch population was concerned, seemed in peril of rebellion. The army corps, which had been mobilized for war, was about to arrive in South Africa; but it was evident that the exigencies of the situation, and the widely divided areas of invasion, would for the

Sir R. Buller's arrival.

time being place in abeyance the original plan which had been formulated for an invasion of the Orange Free State from Cape Colony on three parallel lines. The first duty was to effect the relief of the British forces which had been rendered immobile, and to do this Sir Redvers Buller had no choice but to disintegrate the army corps. Hildyard's and Barton's brigades were sent to Natal; Sir William Gatacre, with a brigade instead of a division, was despatched to Queenstown, Cape Colony; while Lord Methuen, with a division, was sent off at breathless pace to relieve Kimberley. As November wore on, the situation did not improve. Cape Colony was invaded in earnest; while in Natal a flying column of Boers, pushing down from the Tugela, not only captured an armoured train, but for a short time isolated Hildyard's forces concentrating at Estcourt. The situation in Natal seemed so serious that on 22nd November Sir Redvers Buller suddenly disappeared from Cape Town, to arrive in Natal three days later. In the meantime Lord Methuen, with characteristic energy, had commenced his march to the relief of Kimberley. He encountered resistance at Belmont on 23rd. This he brushed aside by direct tactics, and two days later won another step on the stair to Kimberley at Enslin. Still persevering, he moved on to the Modder, where he was seriously opposed by De la Rey and P. A. Cronje, the latter having posted down from Mafeking with 2000 men and arrived on the previous night. The Boers, who held a river line, kept the British attack at bay all night, but eventually fell back, relinquishing the position after dark, as their right had been turned by General Pole-Carew's brigade. It was a long and sanguinary fight, in which the British lost 485 killed and wounded, and what was more serious, Lord Methuen (himself wounded) found that his force had exhausted its forward momentum, and that other than heroic tactics would have to be employed to raise the siege of Kimberley. The extent of the operations and the gravity of the situation now began to be felt in England, every available man was called up from the reserves, and the War Office made what at the time appeared to be adequate provision for the waste which it was seen would occur in a war under modern conditions. On 30th November the mobilization of a sixth division was ordered, offers of Colonial aid were accepted, and every facility provided for local recruiting in the South African ports. All through the early weeks of December confidence was considerably restored. Buller was arranging for the relief of Ladysmith, which had already shown its spirit by two successful sorties to the besiegers' batteries. In every theatre the British strength was consolidating. But the full significance of British incapacity to cope with the situation presented by these two small nations in arms had not yet been appreciated. The confidence restored by the lull during the early part of December was destined to be roughly shattered. On 10th December Gatacre essayed a night march and attack upon the rebel position at Stormberg, and was himself surprised and beaten (719 killed, wounded, and missing). On the following day Lord Methuen delivered an attack upon the Spytfontein kopjes (Magersfontein), and failed hopelessly, losing General A. Wauchope and over 950 officers and men. But even this could be suffered with equanimity, since Buller was about to bring his own force into play, and Buller, it was confidently supposed, would not fail. He had collected at Chievely in Natal a brigade of mounted men, four brigades of infantry (Generals Lyttelton, Hart, Barton, and Hildyard), and two brigade divisions of artillery, and he carried with him the trust alike of the army and the nation.

Failures of Lord Methuen and Gen. Gatacre.

On 16th December the whole Empire was prostrated with the news that Buller had made his effort and failed; that he had essayed an assault upon the positions fortified north of the Tugela by the Boers, under their newly found general Louis Botha, and that he had been repulsed with the loss of 1100 men and 10 guns. The full nature of the failure was not realized by the British public, nor the spirit in which the general had received the finding of fortune. How he had lost heart, and actually suggested the surrender of Ladysmith, was only known to them later, but the Cabinet knew, and in the face of the serious situation thus created the Cabinet took strong action. They appointed Field-Marshal Lord Roberts, V.C., to the supreme command in South Africa, with Lord Kitchener as his Chief of the Staff. A wave of military enthusiasm shook the Empire, and as the final requisition for mobilizing a seventh division practically drained the mother-country of trained men, a scheme for the employment of amateur soldiers was formulated, resulting in the Imperial Yeomanry and Volunteer movement, which proved one of the most striking features of the South African campaign. Pending the arrival of Lord Roberts and reinforcements, the situation in South Africa remained at a deadlock: the three besieged towns—Mafeking, Kimberley, Ladysmith—still held their own, but no headway was made by the relief columns; all they could do was to stand on the defensive. The only bright spot, as far as the British were concerned, was to be found in northern Cape Colony, where General French, with two cavalry brigades and a scratch force, was able, by a magnificent display of strategy, to keep at arm's length a superior force of the enemy, over a front of thirty miles in the vicinity of Colesberg. General French's achievement during this phase of the war was the more noteworthy since he had pitted against him the military skill of both De la Rey and De Wet, two of the three men of military genius produced by the war on the Boer side. On 6th January the Boers in Natal made a desperate attempt to reduce Ladysmith by storm. The garrison, already weakened by privation and sickness, made a stubborn resistance, and after one of the most sanguinary engagements of the war, at Cæsar's Camp and Wagon Hill, the garrison repulsed the attack with severe loss to the enemy, itself having 500 casualties, including Lord Ava, the eldest son of the Marquis of Dufferin.

Buller's failure: Lord Roberts appointed to the command.

When Lord Roberts arrived in Cape Town on 10th January, 1900, three garrison towns were still invested, and the relieving forces were still maintaining their rôle of passive resistance. The Commander-in-Chief's first duty was to create out of the tangle of units in Cape Colony a field army capable of advancing into the enemy's country *vid* the Orange Free State. In the meantime, Sir Redvers Buller, who had been reinforced by Sir Charles Warren and a division, essayed a second attempt to cross the Tugela, by turning the Boer left. But the movement, sound in its conception, was indifferently carried out, with the result that the disastrous action at Spion Kop (24th January) was fought, and the British were obliged to retire again across the Tugela. (British losses, 1700.) By 1st February Lord Roberts had begun to feel his way, and on 3rd February he ordered a demonstration against the right of the Boer position at Spytfontein to Koodoosberg to cover the withdrawal of General French and the cavalry from before Colesberg, and the concentration of his army at Modder River. In spite of another set-back in Natal to Sir Redvers Buller, who had essayed a third attempt to relieve Ladysmith on 5th February, and failed to make good the purchase which he secured across the Tugela, Lord Roberts matured his plans, and, arriving at Modder River

Spion Kop.

Roberts's advance.

on 9th February, he set his operations in motion two days later by detaching French to the relief of Kimberley. On the 15th February, French at the head of his cavalry galloped into Kimberley, spreading dismay through the ranks of the burghers under Cronje, who vacated the Spytfontein positions on the night of the 15th, and retreated along the line of the Modder, crossing the front of the infantry division which was pushing up into the gap made by the cavalry advance. Lord Kitchener, who was with the infantry, at once sent the mounted infantry in pursuit and changed the direction of the infantry, sending word to French to bring his cavalry across to Koodoosrand Drift. French, with that unfailing energy which is the true attribute of a cavalry leader, conformed to Kitchener's urgent appeal, and on the 17th seized the hills above Paardeberg just in front of Cronje's advance-guard. Thus checked, the pursuing infantry crashed into him on the 18th. Kitchener, who as chief of the staff issued orders, attempted to reduce Cronje, now in the river bed, by a *coup de main*, which, though costing over 1000 casualties, compressed Cronje into the confined area from which he was only to leave as a prisoner of war with 4000 of his men on 27th February, the anniversary of Majuba. Lord Roberts's bold plunge into the Free State had automatically relieved the pressure in front of Buller, who after desperate fighting was able to turn the left flank of Botha's position at Colenso, and after ten days' fighting to relieve Ladysmith on the 28th February. Ladysmith had fared worst of all the beleaguered garrisons, and its 22,000 inhabitants were almost at their last gasp when relief came. The casualties from shell fire had only been 66, but those from sickness were many times as heavy as those by the chances of war. The relief had not been without a strain: Buller's operations had cost at Colenso 1200 men, at Spion Kop 1700 men, at Vaalkranz 400, and now in the last long-drawn effort 1600 more—over 5000 in all. But the tide of war had changed. The Natal invaders fell back to the mountains which enclose the north of the colony; Olivier and Schoeman retired from Cape Colony before Gatacre and Clements; and the Presidents of the Republics, realizing that the British Empire was capable of more resistance than they had calculated upon, put forward feelers aiming at the restoration of the *status quo* before the war. These proposals were rejected by Lord Salisbury: there could be no end now but a complete destruction of the Boer power.

Paardeberg.

Relief of Ladysmith.

The surrender of Cronje and the relief of Ladysmith for the time being paralysed the Boer resistance. Two half-hearted attempts were made on 7th and 10th May, at Poplar Grove and Driefontein, to stem Lord Roberts's advance upon Bloemfontein, President Kruger himself arriving on the scene to give confidence to his burghers; but the demoralization was so great that neither the military genius of the few nor the personal influence of the President could bolster up an adequate resistance, and on 13th March 1900 Lord Roberts's army marched into the Free State capital. This great move of the Field-Marshal's, accomplished in spite of the loss of a convoy which cut down his reserve supplies by two-thirds, and only possible by reducing the ration of the fighting man to a minimum and by undertaking the almost unprecedented risks of changing the line of communication three times, was followed by a period of reaction. It was not until 29th March that the new railway communication recommenced to feed the army. In the meantime rebellion had broken out in the Prieska district of Cape Colony, which was promptly quelled by Lord Kitchener. The halt at Bloemfontein was marked by the publication of proclamations, offering protection to the burghers, which, however, the invaders had not yet the power to fulfil. The enforced halt was unfortunate; it not only resulted in a bad outbreak of enteric, but it gave the Boers time to recuperate, and by the beginning of April they again took the initiative. The death of their commandant-general, Piet Joubert, on 28th March, seemed to mark a change in the fortunes of the Republican army. Commandant De Wet, who had first come into prominence as the capturer of Lord Roberts's convoy at Waterval, now added to his laurels by ambushing Broadwood's mounted brigade at Sannah's Post, just outside Bloemfontein, on 31st March, while four days later he reduced a detachment of Irish Rifles at Reddersburg, and then went south and invested Colonel Dalgety and a mixed force at Wepener, which was relieved after ten days by General Hunter's division, brought round to Aliwal North from Natal.

Capture of Bloemfontein.

These successes were not able to retard Lord Roberts's progress. It took the Field-Marshal six weeks to reconstruct his plan of operations, and on 1st May the grand army moved northwards upon the Transvaal capital. The main advance was taken with one cavalry and three infantry divisions (the cavalry commanded by French, and the infantry divisions by Generals Tucker, Pole-Carew, and Ian Hamilton). Rundle's division took the right of the advance; Methuen and Hunter, moving from Kimberley, formed the left. Kelly Kenny, Colvile, and Chermside held the communications based on Bloemfontein. A flying column detached from Hunter, under Mahon, in conjunction with Plumer from the north, relieved Mafeking (where Baden-Powell aroused world-wide enthusiasm by his resistance) on 17th May, the same day that the Natal field force under Buller moved up into the Biggarsberg and occupied Dundee. On 10th May Lord Roberts had crossed the Zand River; on 12th May he entered Kroonstad. After a halt of eight days at Kroonstad, the grand army again moved forward and marched triumphantly, meeting but small resistance, without a halt into Johannesburg, which was occupied on 31st May, the Orange Free State having been formally annexed by proclamation three days earlier. On 30th May President Kruger fled his capital with the State archives, taking up his residence at Waterval Boven on the Komati Poort line. But while the gold mines were now in the possession of the British, attacks were made on their line of communications by De Wet, who from this period organized a guerilla resistance which he maintained until the end of the war. On 5th June Lord Roberts's army occupied the capital of the Transvaal practically without resistance, setting free about 3000 British prisoners of war detained there.

Relief of Mafeking.

Capture of Pretoria.

It had been anticipated that the occupation of both the capitals would have brought the hostilities to a close, but this was not the case, and though after 5th June regular resistance was at an end, the occupation was met with two years of almost unparalleled and unprecedented partisan warfare. On 8th June Sir Redvers Buller forced his way over Alleman's Nek, and on the following day occupied Lang's Nek, while the Field-Marshal fought a more or less decisive action against Botha, De la Rey, and Kemp at Diamond Hill, 20 miles east of Pretoria. The pressure on the main communications was now so serious that a force was thrown back into the Orange River Colony under Hunter, which in co-operation with Rundle's division accomplished the surrender of Prinsloo with 3000 Free Staters in the Brandwater basin (29th July). A week before this satisfactory result the Field-Marshal had initiated a movement from Pretoria to sweep down to Komati Poort on the Portuguese frontier,

Prinsloo's surrender.

in which Buller, advancing from the south, was to co-operate. On August 26–27 the combined forces engaged and defeated Botha at Dalmanutha and Bergendal, with the result that the enemy dispersed into the bush-veld north of the Middelburg railway. On 30th August the remainder of the British prisoners were released at Nooitgedacht. On 6th September Buller occupied Lydenburg in the bush-veld, and five days later the aged President of the Republic, fleeing his country, took refuge in Lorenzo Marques. On 13th September Barberton was occupied, and on the 25th the Guards Brigade occupied Komati Poort. In October the military operations were confined to attempts to reduce guerilla commandoes which had taken the field. Mr Kruger, deserting his countrymen, left for Europe in a Dutch man-of-war, and General Buller sailed for Europe. On the 25th of this month Lord Roberts formally annexed the Transvaal as an integral portion of the British Empire.

Flight of Mr Kruger.

In November there seemed to be evidences that the back of the trouble was broken, and the Field-Marshal, who had been appointed Commander-in-Chief at home, left South Africa, handing over the command of the army of occupation to Lord Kitchener. Then followed a long period of groping for a means to cope with the development of guerilla tactics, which for the next six months were at their zenith. The railway communications were constantly damaged, isolated posts and convoys captured, and the armed guerilla bands always seemed able to avoid contact with the regular columns sent in pursuit. Before the close of 1900 they scored several signal successes. De Wet captured Dewetsdorp, Kemp defeated Clements in the Hekpoort Valley, and disaffection broke out in Cape Colony to an alarming degree, while, as forerunners of the promised invasion, scattered bodies of Free Staters crossed south of the Orange river to swell the rebellion. Against this the British scored one success, namely, the severe handling of De Wet's commando at Bothaville, when the gallant Le Gallais lost his life. The year closed badly, as the commandoes, under the direct influence of Louis Botha, attacked the whole of the railway posts on the Middelburg railway and captured Helvetia, with its 4·7 gun, though two attempts at invasion of Cape Colony in force had been frustrated by the watchfulness of Charles Knox's columns. Lord Kitchener called for more men, and on 22nd December the War Office announced that 30,000 more mounted men would be despatched to the seat of war.

Lord Kitchener takes command.

With the opening of 1901 Lord Kitchener tried new schemes. He withdrew all his detached garrisons except in the most important centres, and set himself to make his railway communications perfectly secure. He determined to make the area of operations a waste, and instituted the concentration camps, into which he intended to bring the whole of the non-combatant inhabitants of the two republics. He despatched French with a large force to clear the south-eastern districts of the Transvaal; and for the rest maintained a force to watch De Wet, and organized a defence force in Cape Colony, while using the residue of his mounted men to sweep the country of stock, forage, and inhabitants. Although there were no great disasters, the new policy was not prolific in success. The enemy invariably dispersed before superior forces; and the removal of the women and children from the farms did not have the effect of disheartening the burghers as had been anticipated—it rather mended their vitality by relieving them of responsibility for their families' welfare. On 10th February De Wet, with five guns and 3000 men, carried out his promised invasion of Cape Colony. This invasion was a fiasco; by judicious use of the railway Kitchener concentrated sufficient troops in the Colony to cope with the attempt, and, after being hunted from pillar to post for eighteen days, De Wet escaped back into the Orange River Colony with the loss of all his guns, munitions of war, and half his force. On 3rd March De la Rey, the lion of the western Transvaal, essayed an attack upon Lichtenburg, in which he was heavily repulsed. Signs of weakness were now apparent, and as a result Louis Botha, acting with the authority of Schalk Burger, the representative of President Kruger, opened negotiations with Kitchener. A meeting took place at Middelburg, Transvaal, on 28th February. These negotiations, however, broke down, mainly over the treatment to be awarded to Cape rebels.

Concentration policy.

The hostilities now entered upon a new phase. The establishment of a line of defensive posts between Bloemfontein and Ladybrand had given Kitchener an idea, and he resolved upon the scheme of partition of the theatre of war by chains of blockhouses. In the meantime, while these posts were under construction, the harrying of the guerillas by mobile columns was continued. In March Babington captured three guns and six maxims from De la Rey near Ventersdorp. In April Plumer occupied Pietersburg, the last remaining seat of government open to the enemy. Rawlinson captured a laager and guns at Klerksdorp. In May matters had so far improved that municipal government was given to Johannesburg, and a certain number of mines were allowed to recommence operations. De la Rey was defeated by Dixon at Vlakfontein, after a desperate encounter. June brought little of moment, though the Boers scored two minor successes, Kritzinger capturing the village of Jamestown in Cape Colony, and Hindon reducing the camp of the Victorian M.I. at Wilmansrust. In July there were further evidences of weakness on the part of the Boers, and Botha applied for permission to communicate with ex-President Kruger. This was allowed, but, as Mr Kruger advised a continuance of the struggle, the slow course of the war continued. In the meantime, the concentration camps were becoming filled to overflowing, and a steady stream of captures and surrenders were reducing the hostile power of the republics. On 13th July President Steyn only escaped capture by Broadwood at Reitz by a few minutes; and on 20th July the aged wife of the ex-President died in Pretoria. August was an important month, as in it Kitchener promulgated a proclamation, formally threatening the Boer leaders who should not surrender with permanent banishment from South Africa: this proclamation, though supported by the home Government, unfortunately had very little effect. Kitchener also received letters from the Boer leaders, showing that they were still determined to keep the field. September showed some slight improvement in the situation in Cape Colony, where General (now Sir John) French was in supreme command. On the 5th, Scobell captured Lotter, who was subsequently executed for murder; though this was rather balanced a few days later by Smut's attack on the 17th Lancers. Botha made a despairing effort to reinvade Natal, but his plans were rendered abortive by his failure to reduce the posts of Mount Prospect and Fort Itala, which he attacked on 26th September. De la Rey was also defeated in the west, in an attack upon Colonel Kekewich's camp at Moedville. Desultory fighting continued till the close of the year, the balance of success being with the British, though on 30th October Colonel Benson's column had been defeated by Botha, at Brakenlaagte, in the south-eastern Transvaal. Affairs again took an unsatisfactory turn in Cape Colony, and on 8th October the whole colony was placed under martial law. But in December matters improved, and

Blockhouse policy.

Guerilla warfare.

General Bruce Hamilton's column, by a series of night marches, practically blotted out the resistance in the eastern Transvaal. The corps of National Scouts (burghers who had come over) was inaugurated, and matters so far mended in Johannesburg that the Stock Exchange reopened. By the end of the year the blockhouse system was complete, but this phase of the war was destined to close badly, as De Wet on Christmas Eve captured the whole of Colonel Firman's Yeomanry camp at Tweefontein, Orange River Colony.

With 1902 the last phase of this protracted struggle commenced. The blockhouse system was practically finished, and Kitchener determined upon a new means of harassing the enemy, who still had a total of about 25,000 men in the field. But the blockhouses had already begun to serve the purpose for which they were designed. In the past the mobile columns, of which there were over sixty in the field, had always been bound to the railway for supply; now convoys could be pushed out to them along whatever blockhouse line they touched. In January Bruce Hamilton continued his successful night marches, and late in the month General Ben Viljoen was captured in the Lydenburg district. The only set-back was the descent which Beyers made upon Pietersburg, breaking into the concentration camp and carrying off a number of able-bodied refugees. Early in February Lord Kitchener commenced his first drive at Wolvehoek, and it was so successful that it was evident that the key to the situation had been found. As a mark of its success it drove the enemy still in the field to desperation, and for the rest of the winter were chronicled alternate successes and disasters. A British convoy was captured in the Colony; the 28th Mounted Infantry were overwhelmed at Klip Drift; the Scots Greys were roughly handled; De la Rey captured von Donop's convoy. But against this could be set off the capture of a whole commando by Colonel Park, A.D.C., the capture of Hans Grobler's commando by Colonel Colin Mackenzie, and a successful drive in the north-east of the Orange River Colony which resulted in 600 prisoners. March was perhaps the most important month in the last stage of the war. It opened with another success to De la Rey, who captured Paris's column and Lord Methuen; but for the rest, the great drive in the western Transvaal proved to the Boers the futility of any attempt to prolong the struggle. On 23rd March the representatives of the Boer Government came into Pretoria, six weeks were spent in negotiation, and then a monster meeting of delegates, under the presidency of General Kemp, was held at Vereeniging.

The "drives."

As a result of this conference a peace was ratified at Pretoria on 31st May, and the South African war was a history of the past. The terms of peace may be condensed into the following points: (1) Surrender of all burghers in the field, with all arms and munitions of war; (2) all burghers duly declaring themselves subjects of King Edward VII. to be repatriated; (3) no burghers who should surrender to be deprived of either their liberty or property; (4) no proceedings to be taken against burghers for any legitimate acts of war during the period of hostilities; (5) the Dutch language to be taught in public schools on the request of parents, and to be allowed in courts of law; (6) sporting rifles to be allowed upon the taking out of licences; (7) the military administration to be superseded by civil administration as soon as possible, the civil administration to lead up to self-government; (8) the question of the native franchise not to be considered until after the introduction of self-government; (9) landed property not to be subjected to any special tax to defray the cost of the war; (10) a commission to be formed to facilitate the repatriation of the burghers. A grant of £3,000,000 to be given as compensation for the destruction of farms. These terms were signed on behalf of the British Government by Lord Milner and Lord Kitchener; on behalf of the Orange Free State by Messrs J. Brebner, C. R. de Wet, C. Olivier, and Judge J. B. M. Hertzog; on behalf of the Transvaal Government by Messrs S. W. Burger, F. W. Reitz, Louis Botha, J. H. De la Rey, Lucas Meyer, and Krogh.

In the whole war the British lost 5,774 killed and 22,829 wounded, while the Boers lost about 4000 killed. The number of Boer prisoners in the hands of the British at the end of the war was about 40,000.

(L. J*.)

Trapani, a seaport town and episcopal see of Sicily, Italy, on the west coast, 47 miles west by south of Palermo (121 miles by rail). It is a place of some trade, exporting salt, wine, fish, &c., to the annual value of about £100,000 (£116,500 in 1899), and importing wheat, timber, and coals to the value of £350,000 (£359,300 in 1899) annually. The port is the safest and largest on the west coast of Sicily, and gives a depth of 24 feet alongside the quays. It was in 1899 entered by 115 vessels of 84,640 tons. The people engage in tunny and sponge fishing, in the preparation of salt (the salt-pans, 45 in number, stretch from Trapani to Marsala, and produce about 200,000 tons every year), in the manufacture of ice and olive oil, and in alabaster work. The port is constantly dredged, and a second breakwater was built in 1899–1900. There are statues to Garibaldi (1890) and Victor Emmanuel (1882). Population (1881), 33,514; (1901), 60,257.

Trasimeno, or LAKE OF PERUGIA, a lake of central Italy, 12 miles W. from Perugia. Area of lake, 59 square miles. Having no natural outlet, it was subject to sudden and serious rises of the surface, which occasioned inundations, and these in turn malaria. Through the exertions of Cav. G. Pompili an artificial outlet, consisting of alternate canals and tunnels, has been made from the S.E. corner of the lake to the Caina, a small tributary of the Tiber. The work, which is about 4 miles long, cost only about £26,000, and was completed in 1898. It is estimated to leave about 2500 acres of land dry, and to convert another 2800 acres of marshy soil into cultivable land.

Tras-os-Montes, a former province of Portugal, situated in the extreme N.E. of the country, and washed on the S. by the river Douro. It corresponds to the districts of Bragança and Villa Real. In addition to port wine, it produces olive-oil, corn, and vegetables. Cattle and sheep breeding are considerable industries. Area, 4291 square miles. Population (1900), 429,170.

Traú (Serbo-Croatian, *Trogir;* Latin, *Tragurium*), a coast town of the Austrian crownland of Dalmatia, a few miles west of Spalato. It is situated on a small island in the Canale di Traú, and is connected with the mainland and the adjoining island of Bua by two bridges. It has a number of interesting architectural and historical remains, including the ruins of a Venetian fortification and a loggia, said to be "a perfect example of a public court of justice of the Venetian period," together with a beautiful 13th-century basilica, &c. The town is a steamship station (indifferent harbour), and has some trade in wine, figs, olives, and other fruit, the port being entered and cleared by 400,000 to 500,000 tons annually. In 1890 the population of the town was 3392, and of the commune 15,809 (1900, 17,064), chiefly Croatians.

Traunstein, a town and summer resort of Bavaria, Germany, district of Upper Bavaria, 73 miles by rail east-south-east of Munich. It is one of the Bavarian towns which distil salt from the brine of Reichenhall, whence (22 miles distant) it is brought in pipes. It has a historical museum, a couple of fine fountains (1526 and 1894), and monuments of the war of 1870–71 and to King Maximilian II. There are saline baths, whey cure, and breweries. In the vicinity are Empfing, with baths of all kinds, and Pastor Kneipp's cold-water cure establishment. Population, (1885), 4909; (1900), 7516.

Trautenau (Czech, *Trutňov*), the chief town of a government district in Bohemia, situated on the Aupa, a tributary of the Elbe, at the foot of the Riesengebirge, in the frontier district adjoining Prussian Silesia. It is the centre of the Bohemian linen industry, and has a yarn exchange. In addition to its spinning and weaving establishments, it has factories for the manufacture of paper and for the utilization of the waste products of the other mills. Trautenau was founded by German colonists invited to settle there by King Otto II. of Bohemia, and received a charter as a town in 1340. It was the scene of two battles between the Prussians and Austrians on 27th and 28th June 1866, which are now commemorated by public monuments. Population (1890), 13,290; (1900), 14,777.

Travancore, a state of southern India, in connexion with Madras. Area, 6370 square miles; population (1881), 2,401,158; (1891), 2,557,736, showing an increase of 7 per cent., which has been continuous since 1875; average density, 380 persons per square mile. In 1901 the population was 2,951,038, showing a further increase of 15 per cent.

The gross revenue is Rs.88,55,000; tribute, Rs.8,10,652; military force, 1360 infantry, 61 cavalry, and 30 artillery with 6 guns; number of police, 1632, under a European officer; number of schools (1897–98), 3274, with 160,368 pupils, of whom 36,562 were girls; proportion of pupils to population of school-going age, 40 per cent. (being 64 per cent. for boys and 19 per cent. for girls), compared with 15·5 per cent. for the Madras Presidency; registered death-rate (1897), 15 per 1000. The Maharaja of Travancore claims descent from Cheraman Perumal, the last Hindu monarch of united Malabar in the 14th century. Though he is a Kshatriya, the succession follows the local custom of inheritance through females; consequently his *sanad* of adoption authorizes him to adopt sisters' sons. For two or three generations the rulers have been men of education and character, and the state is conspicuous for good administration and prosperity. The two dominant sections of the population are the Namburi Brahmans and the Nairs or military caste. Native Christians, chiefly of the Syrian rite, form just one-fifth of the whole, being more numerous than in any Madras district. In 1897–98 the chief items of gross revenue were: land, Rs.22,71,000; salt, Rs.19,00,000; tobacco, Rs.10,49,000; customs, Rs.6,42,000; excise, Rs.6,35,000; forests, Rs.4,37,000; and stamps, Rs.3,56,000. The expenditure included Rs.22,95,000 on public works and Rs.3,17,000 on education. The value of the sea-borne trade in that year, mainly of a coasting character, was Rs.2,47,98,100, of which Rs.1,46,93,752 represented exports, chiefly cocoanut products, timber, pepper, cardamoms, coffee, and tea. The principal ports are Alleppi, Quilon, and Paravur; but there is no real harbour. Proposals have been considered for constructing a railway over the hills into British territory (including a line from Quilon to Tinnevelly). The Periyar project conducts water across the range in a tunnel to irrigate Tinnevelly district, for which compensation of Rs.40,000 is annually paid to Travancore. The capital is Trivandrum.

Traverse City, a city and lake port of Michigan, U.S.A., capital of Grand Traverse county, at the head of the west arm of Grand Traverse Bay, on the north-western coast of the Lower Peninsula, at an altitude of 605 feet. The harbour is good, and there is regular steamer communication during the open season with Chicago and other lake ports. The surrounding region is forested with pine, and the industries are chiefly connected with lumber, there being saw, planing, and shingle mills. Population (1880), 1897; (1890), 4833; (1900), 9407, of whom 2068 were foreign-born.

Treaties.—Since the publication of the article on TREATIES in vol. xxiii. of this Encyclopædia, treaty-making has entered more largely than ever into the life of nations. In the earlier article the different kinds of treaties were classified as (1) political; (2) commercial; (3) relating to social intercourse; (4) to extradition; (5) to copyright, trade-marks, &c.; (6) to the conduct of war. To these we may now add a seventh class, relating to international arbitration.

1. Among the treaties belonging to the first class, concluded since 1888, two recent ones stand out as of first importance. The Hay-Pauncefote Treaty, signed at Washington 18th November 1901, and ratified by the American Senate 16th December 1901, to facilitate the construction of a ship canal through the Central American isthmus, and to remove any objection arising from the Convention of 19th April 1850, known as the Clayton-Bulwer Treaty, adopted as the basis for its neutralization the form of the International Convention of 29th October 1888 for the free navigation of the Suez Canal. On 30th January of 1902 an Anglo-Japanese Treaty was signed in London, having for its object the maintenance of the "*status quo* and general peace in the extreme East," and more especially "the independence and territorial integrity of the empire of China and the empire of Corea," and to secure "equal opportunities in those countries for the commerce and industry of all nations." It provides that, if either Great Britain or Japan should become involved in war with another Power through the defence of its interests in the countries concerned, the other will maintain a strict neutrality, and, if any further Power or Powers should join in the hostilities against either ally, the other contracting party will come to its assistance. A great number of conventions and arrangements of less importance dealing with the delimitation of frontiers and spheres of influence in Africa and elsewhere have also been concluded between Great Britain and different European Governments (see Hertslet's *Treaties*, vols. xviii., xix., xx., and xxi., and the "Treaty Series" published by the British Government), as well as with many native states in Africa, on the Persian Gulf, and in the Malay Peninsula. By a declaration signed at London 5th August 1890, France recognized the British protectorate over Zanzibar and Pemba, and Great Britain recognized the French protectorate over Madagascar; the appointment of a commission to settle the details of their respective spheres of influence in Africa set out in the declaration was also agreed to. By the declaration signed at London 15th January 1896, Great Britain and France settled their respective territorial policies on the Petcha Bouri, Meiklong, Menam, and Bang Pa Kong rivers. By this declaration also the two Governments agreed that all advantages in the Chinese provinces of Yunnan and Szechuen obtained by either Government

should be enjoyed by both in common; the appointment of a commission to delimit the French and British possessions to the west of the Lower Niger was agreed upon; and arrangements were made for the conclusion of a convention with regard to commercial matters in Tunis (see *infra*). By an agreement dated 1st July 1890 Great Britain ceded to Germany the island of Heligoland. By this same agreement spheres of influence of the two countries in Africa were fixed (details to be ascertained by a mixed commission, whose proposals were embodied in an Anglo-German agreement signed at Berlin 23rd February 1901), and Germany recognized a British protectorate over Zanzibar and Pemba. The Samoan Islands were divided up under a "convention and declaration between Great Britain and Germany" signed at London 14th November 1899, which was completed by a tripartite convention between Great Britain, Germany, and the United States, signed at Washington 2nd December 1899.

2. British commercial treaties since 1888, in chronological order, include a general treaty of commerce and navigation with Mexico (27th November 1888); with Egypt (29th October 1889); with Greece (28th March 1890); with Muskat (19th March 1891); with Portugal, spheres of influence in Africa, transit dues, &c. (11th June 1891); with Servia (10th July 1893); with Japan (16th July 1894); with France, commercial relations between France and Canada (4th October 1895); with Abyssinia (14th May 1897); with Bulgaria (24th July 1897); with France in connexion with Tunis (18th September 1897); with Belgium—a provisional *modus vivendi*, with subsequent extensions to British Colonies (27th July 1898); with Uruguay (15th July 1899); and others of less importance. By an exchange of Notes on 28th April 1899 Russia and England determined the territorial limits of their respective railway interests in China; and by an agreement and exchange of Notes on 16th October 1900 Great Britain and Germany declared their intention to observe an open-door commercial policy in China, while respecting its territorial integrity. A new commercial treaty with China was signed 5th September 1902. For the Sugar Convention, see SUGAR.

3. There have been a great number of minor accessions to existing postal and telegraphic conventions.

4. Extradition treaties are dealt under EXTRADITION.

5. The international protection of copyright and industrial property (patents, trade marks, &c.) has undergone considerable extension (see *infra*).

6. To treaties relating to the conduct of warfare a great addition has been made by the two international conventions adopted at The Hague on 29th July 1899. By the first the principles of the Geneva Convention of 22nd August 1864 were adapted to maritime warfare. By the other the laws and customs of war by land in a great many cases were formulated, and it was provided that "until a more complete code of the laws of war" was issued "populations and belligerents" should remain "under the protection and empire of International Law" (see WAR).

7. There have been several important treaties relating to arbitration (see ARBITRATION, INTERNATIONAL), the most recent being the references of the Waïma and "Sergent Malamine" incidents by Great Britain and France to the decision of Baron Lambermont (3rd April 1901), and that of the difficulties arising out of the determination of the boundary between Brazil and British Guiana to the king of Italy (6th November 1901). A new departure in treaty-making in this connexion is that of treaties specifically and exclusively devoted to providing for arbitration generally as between the contracting states. The first of these treaties was the Italo-Argentine Convention (23rd July 1898). The Anglo-American Convention for the same purpose was signed (12th January 1897), but was not ratified by the American Senate.[1] For The Hague Convention, creating a special court, see ARBITRATION, INTERNATIONAL. A Chile-Argentine Convention, providing like the Italo-Argentine Convention for compulsory arbitration, was signed on the 12th August 1902.

Among new and interesting developments which have arisen, we may also place the international unions, or open international arrangements, which all states can join on subscribing to certain conditions. These international unions date from the formation of the Union Postale Universelle in 1874.[2] It has been followed by others relating to industrial property (patents, trade marks, &c.), copyright, railway traffic, the protection of submarine cables, suppression of African slavery, and Suez Canal quarantine (19th March 1897). The union relating to the protection of industrial property, to which the Governments of Belgium, Brazil, Spain, France, Guatemala, Holland, Portugal, Salvador, Servia, and Switzerland subscribed, was concluded at Paris on 20th March 1893, and since that date Great Britain (with New Zealand and Queensland), Sweden, Denmark, Norway, Italy, Japan, the United States, and Tunis have acceded to its terms and joined the union. Turkey and Salvador have since withdrawn from it.[3] The subjects or citizens of each of the contracting states enjoy, in all other states of the union, as regards patents, designs, models, trade marks, and trade names, all the advantages their respective laws grant to their own subjects or citizens, and consequently have the same protection as the latter and the same legal remedy against any infringement of their rights, provided they observe the formalities and conditions imposed on subjects or citizens by the internal legislation of each state. They have also a right of priority in respect of registration in the respective states. The International Copyright Union was created by the Berne Convention of 9th September 1886. Both unions maintain official bureaus at Berne, and issue periodical publications. The Railway Traffic Union applies to European continental goods traffic only (14th October 1890). Under a convention, signed 5th July 1890, thirty states, including Great Britain and most British colonies, are associated for the prompt publication at an office, established at Brussels, and at their joint expense, of the customs tariffs of the world and all modifications thereof. The General Act for dealing with the suppression of African slavery (signed at Brussels on 2nd July 1890) maintains offices at Brussels and Zanzibar for the centralization of all information and measures connected with the matters dealt with in the General Act.

Further subjects which have been suggested for universal international regulation are anarchist conspiracies, the control of floating pauper populations, the white slave traffic, &c. One of the most remarkable instances of the tendency which states have at the present day to assimilate their intercourse to that between individuals is the conclusion of arrangements for the granting to each other of *leases*. As between European states and Oriental states some such arrangements were made in the form of concessions granted to European settlements; but as between European peoples

[1] The majority of forty-two to twenty-six in its favour did not amount to the two-thirds required by the United States Constitution in such cases.

[2] Before this a Double Standard Monetary Union (23rd December 1865) had been created as between France, Italy, Belgium, and Switzerland (Greece only joined the union in 1868), and a Single Standard Union (1873) between Sweden, Norway, and Denmark. These earlier unions were limited in their area.

[3] Similar arrangements for the mutual protection of inventions, designs, and trade marks have been made between Great Britain on the one side and each of the following states and colonies on the other: Ecuador (designs and trade marks only); Greece (designs and trade marks only); Honduras; Mexico; Paraguay; Rumania (designs and trade marks only); Tasmania; Uruguay; Western Australia.

such a case as that of the grant by Great Britain of leases to France of stations on the Niger (14th June 1898) is novel. Great Britain has taken similar leases of Wei-hai-Wei (1st July 1898) and of territory described as "Hong Kong extension" (9th June 1898).
(T. Ba.)

Trebizond.—(1) A vilayet of Asiatic Turkey, situated on the south coast of the Black Sea, between 36° and 41½° E. It has an area of 12,387 square miles, and is divided into four sanjaks—Janik (Samsún), Trebizond, Lazistán, and Gumush-khaneh. The vilayet consists of a long irregular strip of coast country, the eastern half of which is deeply indented and mountainous. The mineral wealth is great and the soil extremely fertile. There are extensive forests of pine, fir, oak, elm, and chestnut. Large quantities of walnuts are grown. In 1900 the exports amounted to £1,302,640 and the imports to £1,795,760. The population consists of 932,800 Moslems and 231,200 Christians, of whom 181,100 are Greeks. The people are Laz, Georgian, Greek, and Armenian, with a few Kurds, Tatars, Persians, and Europeans. (2) The chief town of the vilayet (the Greek *Trapezus*), and a military station, situated on the south coast of the Black Sea, and connected with Constantinople and Batum by sea and with Erzerum by a *chaussée* which forms part of the caravan route to Persia. The only harbour is the bay on the east, which is exposed to north and north-east winds, and is unsafe during their prevalence. In winter there are heavy gales from the north-east with sleet and snow, but the snow rarely lies. In 1900, including the Persian transit trade (£629,800), which is decreasing annually, the exports—cattle, hazel-nuts, tobacco, carpets, tumbeki, &c.—were valued at £760,670 (as compared with £565,200 in 1876), and the imports—cotton and woollen goods, petroleum, &c.—at £1,323,850 (£1,329,400 in 1876). Trebizond is the seat of British and other consuls. The population comprises 22,000 Moslems and 18,000 Christians. In October 1895 there was a massacre of Armenians, in which the police and soldiers took part.

Tredegar, an urban district (1894) and railway station in the Western parliamentary division of Monmouthshire, England, 7 miles east-north-east of Merthyr Tydfil by rail, on the river Sirhowy. The church of St James was erected in 1890, and the town hall in 1893. There is a large export trade in coal. Population (1891), 17,341; (1901), 18,574.

Treitschke, Heinrich von (1834–1896), German historian and political writer, was born at Dresden on the 15th of September 1834. He was the son of an officer in the Saxon army who afterwards rose to be governor of Königstein and military governor of Dresden. Young Treitschke was prevented by deafness from entering the public service. After studying at Leipzig and Bonn, where he was a pupil of Dahlmann, he established himself as a *privat-docent* at Leipzig, lecturing on history and politics. He at once became very popular with the students, who were attracted by his great oratorical power; but his political opinions, which he brought even into the lecture-room, made it impossible for the Saxon Government to appoint him to a professorship. He was at that time a strong Liberal; he hoped to see Germany united into a single state with a parliamentary government, and that all the smaller states would be swept away. In 1863 he was appointed professor at Freiburg; in 1866, at the outbreak of war, his sympathies with Prussia were so strong that he went to Berlin, became a Prussian subject, was appointed editor of the *Preussische Jahrbücher*, and from that time was one of the ablest advocates of Prussia on the German press. A violent article, in which he demanded the annexation of Hanover and Saxony, and attacked with great bitterness the Saxon royal house, led to an estrangement from his father, who enjoyed the warm friendship of the king. It was only equalled in its ill-humour by his attacks on Bavaria in 1870; his admiration for Prussia made it impossible for him to be just to those Germans who had not, like himself, voluntarily become Prussians. After holding appointments at Kiel and Heidelberg, he was in 1874 made professor at Berlin; he had already in 1871 become a member of the Reichstag, and from that time till his death in 1896 he was one of the most prominent figures in the city. On Sybel's death he succeeded him as editor of the *Historische Zeitschrift*. Among the students he enjoyed great popularity. His ardent patriotism communicated itself to his hearers. He had outgrown his early Liberalism, and become the chief panegyrist of the house of Hohenzollern. He did more than any one to mould the minds of the rising generation, and he carried them with him even in his violent attacks on all opinions and all parties which appeared in any way to be injurious to the rising power of Germany. He supported the Government in its attempts to subdue by legislation the Socialists, Poles, and Catholics; and he was one of the few men of eminence who gave the sanction of his name to the attacks on the Jews which began in 1878. As a strong advocate of colonial expansion he was also a bitter enemy of Great Britain, and he was to a large extent responsible for the anti-British feeling into which so much of German Chauvinism was directed during the last years of the 19th century. In the Reichstag he had originally been a member of the National Liberal party, but in 1879 he was the first to accept the new commercial policy of Bismarck, and in his later years he joined the Moderate Conservatives, but his deafness prevented him from taking a prominent part in debate. He died at Berlin on the 28th of April 1896.

As a historian Treitschke holds a very high place. His work, indeed, lies entirely in the history of the last two centuries. He approached history as a politician; he had none of the passion for research for its own sake, and confined himself to those periods and characters in which great political problems were being worked out: above all, he was a patriotic historian, and he never wandered far from Prussia. His great achievement was the *History of Germany in the Nineteenth Century*. The first volume was published in 1879, and during the next sixteen years four more volumes appeared, but at his death he had only advanced to the year 1847. It will remain a fragment, and it is much to be regretted that he did not live to complete the account of the Revolution, in which he would have had a subject worthy of his peculiar powers. The work shows extreme diligence, scrupulous care in the use of authorities, and in the years he covered he has left little for future historians to discover. It is too discursive and is badly arranged, but it is marked by a power of style, a vigour of narrative, and a skill in delineation of character which give life to the most unattractive period of German history; notwithstanding the extreme spirit of partisanship and some faults of taste, it will remain a remarkable monument of literary ability. Besides this he wrote a number of biographical and historical essays, as well as numerous articles and papers on questions arising out of contemporary politics, of which some are valuable contributions to political thought, while others are political controversy not always of the best kind.

The most important of the essays have been collected under the title *Historische und politische Aufsätze*, in four volumes, Leipzig, 1896; a selection from his more controversial writings was made under the title *Zehn Jahre deutscher Kämpfe;* in 1896 a new volume appeared,

called *Deutsche Kämpfe, Neue Folge*. After his death his lectures on political subjects were published under the title *Politik*. He brought out also in 1856 a short volume of poems called *Vaterländische Gedichte*, and another volume in the following year. The only works translated into English are two pamphlets on the war of 1870, *What we demand from France* (London, 1870), and *The Fire-test of the North German Confederation* (1870).

See SCHIEMANN. *Heinrich v. Treitschke's Lehr- und Wanderjahre, 1836–66*. Munich, 1896. *Gustav Freitag und Heinrich v. Treitschke im Briefwechsel*. Leipzig, 1900. *Deutsche Rundschau*, October 1896; and article by J. W. HEADLAM, *Historical Review*, December 1897. (J. W. HE.)

Trencsén, a corporate town of Hungary, capital of the county of the same name, beautifully situated on the Vág, 70 miles north-east of Pressburg. Near it are the romantic ruins of the fort of Trencsén, which once played an important part in Hungarian history. Trencsén is one of the most considerable towns of upper Hungary, having a gymnasium with interesting collections, a State high school for girls, a public hospital, large barracks, a beautiful park, and several manufactories. The inhabitants of the town and of its vicinity are Slovaks, partly peddlers, who stroll through all parts of Europe with their merchandise. Not far from this town are the hot baths of Trencsén-Teplicz. Population (1891), 6075; (1901), 7011.

Trĕnggânu. See MALAY PENINSULA.

Trent, the chief town of that portion of Tirol, Austria, inhabited by the Italian element, on the left bank of the Adige, 44 miles north by east of Verona. The extensive fortifications are intended for the defence of the Adige valley and the one railway line leading directly from Italy into Tirol. Some of them occupy the isolated rocky height of Doss Trento, which rises about 230 feet above the town. Other outlying forts and batteries command separate ravines, valleys, and positions in the vicinity giving access to Trent from the west (Sarco Thal) and from the east (Val Sugana). Trent has now, in addition to the archiepiscopal seminary with complete theological faculty, an Italian upper gymnasium, an episcopal private gymnasium, a training college for female teachers, a school of commerce, &c. The manufactures comprise, in addition to the silk and textile industry, the preparation of salami, a strongly-spiced Italian sausage, sweetmeats and preserves, spirits, playing-cards, earthenware and furniture. Viticulture and the quarrying of marble and gypsum are also important resources of the inhabitants. A large monument to Dante, designed by Zocchi, was erected in 1896. Population (1890), 21,486; (1900), 24,908, including garrison of 2231 men.

Trente et Quarante, like roulette, is a purely gambling game, for no ingenuity or calculation on the part of the player can enable him to win. No game could possibly be more one of chance. The diagram illustrates one half of the table, the other half precisely corresponding to it. Two croupiers sit on each side of the table, one of them being the dealer; behind the two on the side opposite to the dealer a supervisor of the game has his seat. Six packs of fifty-two cards each are used; these are well shuffled, and the croupier asks any of the players to cut, handing him a blank card with which to divide the mixed packs. There are only four chances at trente et quarante: *rouge* or *noir*, known as the *grand tableau*, *couleur* or *inverse*, known as the *petit tableau*. The stakes are placed on the divisions indicated on the table, the maximum being 12,000 francs and the minimum 20 francs. The dealer, who has placed all the cards before him, separates a few with the blank card, takes them in his left hand and invites the players to stake with the formula, "Messieurs, faites votre jeu!" After a pause he exclaims "Le jeu est fait, rien ne va plus!" after which no stake can be made. He then deals the cards in a row until the aggregate number is something more than thirty, upon which he deals a second row, and that which comes nearest to thirty wins, the top row being always distinguished as *noir*, and the lower as *rouge*. In announcing the result the word *trente* is always omitted, the dealer merely announcing *un*, *trois*, *quatre*, as the case may be, though when forty is turned up it is described as *quarante*. The words *noir* and *inverse* are also never used, the announcement being *rouge gagne* or *rouge perd*, *couleur gagne* or *couleur perd*. Gain or loss over *couleur* and *inverse* depends upon the colour of the first card dealt. If this should be also the colour of the winning row, the player wins. Assuming, for example, that the first card dealt is red, and that the lower row of the cards dealt is nearest to thirty-one, the dealer will announce "Rouge gagne et le couleur." If the first card dealt is red, but the black or top row of cards is nearest to thirty-one, the dealer announces "Rouge perd et le couleur." It frequently happens that both rows of cards when added together give the same number. Should they both, for instance, add up to thirty-three, the dealer will announce "Trois après," and the deal goes for nothing except in the event of their adding up to thirty-one. *Un après* is known as a *refait*; the stakes are put in prison to be left for the decision of the next deal, or if the player prefers it he can withdraw half his stake, leaving the other half for the bank. Assurance against a *refait* can be made by paying one per cent. on the value of the stake with a minimum of five francs. When thus insured against a *refait* the player is at liberty to withdraw his whole stake. It has been calculated that on an average a *refait* occurs once in thirty-eight coups. After each deal the cards are pushed into a metal bowl let into the table in front of the

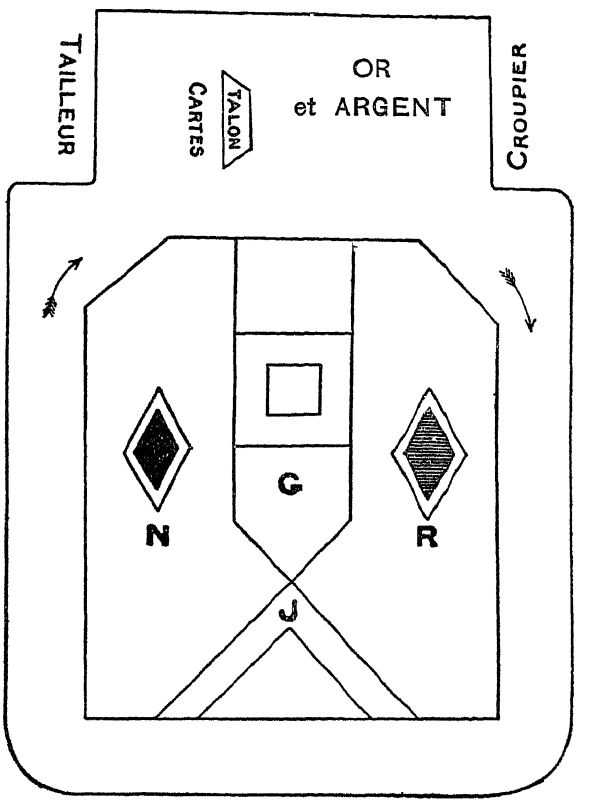

DIAGRAM OF HALF OF TRENTE ET QUARANTE TABLE.
N, *noir*; R, *rouge*; G, *grand tableau*; J, *inverse*.

dealer. When he has not enough left to complete the two rows, he remarks "Les cartes passent"; they are taken from the bowl, re-shuffled, and another deal begins.

(A. E. T. W.)

Trenton, a city of Missouri, U.S.A., capital of Grundy county, on the Grand river, and the Chicago, Rock Island and Pacific, and the Omaha, Kansas City, and Eastern railways, in the northern part of the state, at an altitude of 812 feet. It is in a farming region, for which it serves as a trading centre. It was founded in 1841, incorporated as a town in 1857, and received a city charter in 1893. Population (1890), 5039; (1900), 5396, 192 being foreign-born and 200 negroes.

Trenton, a city of New Jersey, U.S.A., capital of Mercer county and of the state, on the Delaware river, at the falls and head of navigation, on the west boundary of the state. The plan of the city is irregular; it is divided into fourteen wards, has good water-supply and sewerage systems, and is well paved, mainly with brick and asphalt. Among the finer buildings are the state capitol, the public library, the court-house, and the United States building. Trenton is on the main line of the Pennsylvania Railroad from New York to Philadelphia, and on a branch of the Philadelphia and Reading. It is a manufacturing city of great importance. In 1900 there were 570 establishments, with a total capital of $26,174,895. They employed 14,457 hands, and the product had a value of $31,645,695. The chief industries comprised iron and steel, $13,260,787; clay and pottery products, $4,785,142; rubber and elastic goods, $1,689,893; and foundry and machine-shop products, $894,239. For its pottery Trenton has long been famous, and also for the great wire works of the Roeblings. The assessed valuation of real and personal property was in 1900 $33,959,823, the net debt of the city was $2,613,990, and the rate of taxation was $21·50 per $1000. The total receipts, exclusive of loans, were $1,112,963, and the expenditure for maintenance and operation $698,450. At Trenton occurred one of the most celebrated military operations of the American Revolution. On Christmas night, 1776, Washington crossed the Delaware river into New Jersey, and the following day surprised and captured a British force of Hessian mercenaries. Population (1890), 57,458, a great increase since 1880, due in part to the extension of the charter limits; (1900), 73,307, of whom 16,793 were foreign-born and 2096 negroes.

Tréport, Le, a maritime town in the arrondissement of Dieppe, department of Seine-Inférieure, France, 45 miles in direct line N.N.E. of Rouen, on the railway from Beauvais, and at the mouth of the Bresle in the English Channel. It is a sea-bathing station, and a favourite resort of the Parisians. The principal buildings are the hôtel de ville, a tower and the church of St Jacques, both of the 16th century, the latter with fine modern glass, and an ancient timbered house. A casino, surrounded by gardens, was erected at the east end of the beach in 1896–97. The fisheries and oyster parks with their dependent industries and shipbuilding furnish the chief occupations of the inhabitants. The plateau of Mont Huon, rising above the town and reached by an ascent of 380 steps, affords a good view. Three miles east of Tréport is the little bathing town of Mers. Once a mere village, it now provides accommodation for the increasing number of visitors to Tréport. The port comprises a tidal harbour of 14 acres, with 1300 feet of quayage, depth alongside, high spring tide, 20 feet, and a new dock between the tidal harbour and the canal of 7 acres with 900 feet of quayage, depth alongside, 24 feet. The canal from Tréport to Eu has a length of 3 miles, and is navigable by vessels drawing 16 feet. The number of vessels entered in 1900 was 313 of 91,161 tons (from England 306 of 89,006 tons); cleared 354 of 97,471 tons (to England 347 of 96,379 tons). The total port traffic, including coasting trade, amounted to 193,331 tons. Large quantities of sugar, both raw and refined, are exported, chiefly to England, amounting in 1900 to 51,722 tons. Population (1891), 4297; (1901), 4949.

Trevelyan, Sir George Otto, Bart. (1838–——), British author and statesman, only son of Sir Charles Trevelyan, was born on 20th July 1838 at Rothley Temple, Leicestershire. His mother was Lord Macaulay's sister. He was educated at Harrow and at Trinity College, Cambridge, where he was second in the classical tripos. In 1861 he wrote his *Horace at the University of Athens*. The following year he went out as a civil servant to India, where he spent several years. During his stay he contributed *Letters of a Competition Wallah* to *Macmillan's Magazine* (republished 1864). *Cawnpore*, an account of that terrible tragedy, was published in 1865. During the same year he was elected to Parliament for Tynemouth in the Liberal interest. At the general election of 1868 he was returned for the Hawick Burghs, which he continued to represent until 1886. When the first Gladstone Ministry was formed, in December 1868, Mr Trevelyan was appointed Civil Lord of the Admiralty, but resigned in July 1870 on a point of conscience connected with the Government Education Bill. He advocated a sweeping reform of the army, including the abolition of the purchase of commissions, and both in and out of Parliament he was the foremost supporter for many years of the extension of the county franchise. In 1869 he wrote *The Ladies in Parliament*, a humorous political brochure in verse. In the session of 1874 Mr Trevelyan brought forward his Household Franchise (Counties) Bill, which was lost on the second reading; it was not till ten years later that the agricultural labourer was enfranchized. Among other causes which he warmly supported were women's suffrage, a thorough reform of metropolitan local government, and the drastic reform or abolition of the House of Lords. He was also in favour of the direct veto and other temperance legislation. In 1876 he published *The Life and Letters of Lord Macaulay*, one of the most admirable and most delightful of modern biographies; and in 1880 he published *The Early History of Charles James Fox*. In the latter year he was appointed Parliamentary Secretary to the Admiralty. This office he held until May 1882, when, after the assassination of Lord Frederick Cavendish, he became for two years Chief Secretary for Ireland. From November 1884 to June 1885 he was Chancellor of the Duchy of Lancaster. In February 1886 he became Secretary for Scotland, but resigned on 26th March on account of his disagreement with some of Mr Gladstone's Irish Home Rule proposals. The same year he succeeded his father in the baronetcy. At the general election of 1886 Sir George Trevelyan lost his seat for Hawick. As a representative of the Unionist party he took part in the Round Table Conference, and being satisfied with the modifications made by Mr Gladstone in his Home Rule scheme, he formally rejoined the Liberal party. In August 1887 he re-entered the House of Commons as member for the Bridgeton division of Glasgow; and from 1892 to 1895 he was Secretary for Scotland. Early in 1897 he resigned his seat in Parliament and retired into private life. In 1899 he published the first volume of a *History of the American Revolution*, coming down to 1776.

Treves (German, *Trier*), a town and episcopal see of Prussia, in the Rhine province, on the right bank of the Moselle, 69 miles by rail south-west of Coblenz. The most noteworthy of the modern public buildings is the provincial museum, built of red sandstone in 1885–89, and containing antiquities (many of them Roman), pictures, and objects of industrial art. There are also a bronze monument of the Emperor William I. (1893) and a fountain (1897) in commemoration of Archbishop Baldwin. Population (1885), 33,019; (1900), 43,324.

Treviglio, a town of the province of Bergamo, Lombardy, Italy, 15 miles by rail south by west of Bergamo. It has a fine church, an old castle, a technical school, important silk manufactures, wool-spinning, and manufacture of artificial manure, sulphuric acid, and glue. Population (1881), 9854; (1900), 10,000.

Treviso, a town, episcopal see, and capital of the province of Treviso, Venetia, Italy, on the plain between the Gulf of Venice and the Alps, 18 miles by rail north of Venice. In 1890 a monument to Dante (having regard to *Paradiso*, ix. 49) was erected on the bridge at the confluence of the Sile with the Botteniga. Treviso is the seat of various industries—ironworks, majolica and pottery, macaroni, cotton-spinning and rice-husking, paper, printing, brushes, brick-yards, flour-mills—and has a school of the industrial arts and sciences. Population (1900), 34,004.

Triberg, a town and health resort of Germany, grand-duchy of Baden, on the Black Forest Railway, 35 miles south-east of Offenburg, a centre of the Black Forest clock trade. Straw-plaiting, saw-milling, and the manufacture of wooden wares are also carried on. It has a fine waterfall (500 feet), an industrial hall, a nerve-cure establishment, and a couple of technical schools. Altitude, 2251 feet. Triberg is what in Germany is called a "Luft-kurort," to which convalescents resort after a course of baths elsewhere. Population (1900), 3368.

Trichinopoly, a city and district of British India, in the Madras Presidency. The city is on the right bank of the river Cauvery, which here forms an island at the head of its delta, about 56 miles from the sea. It is an important junction on the South Indian Railway, 219 miles south-west of Madras. Population (1891), 90,669; (1901), 104,690, being the largest town in the province after Madras; municipal income (1897–98), Rs.1,58,070. There is still a military cantonment. It has a large Roman Catholic population and several Protestant missions. The well-known Trichinopoly cigars are largely made from tobacco grown outside the district at Dindigul: there are fifteen cigar factories. It has, besides, specialities of goldsmith's work and of modelling in pith. The two colleges (Catholic and S.P.G.) had 335 students in 1896–97; the three high schools, 2604 pupils. There are seven printing-presses, one of which issues a Catholic periodical in Tamil, a reading-room and library. Bishop Heber died here in 1826.

The district of TRICHINOPOLY has an area of 3631 square miles. Population (1881), 1,215,033; (1891), 1,372,717, showing an increase of 13 per cent. after the famine of 1876–78; average density, 378 persons per square mile. Native Christians, mostly Catholics, numbered 69,410, or 5 per cent. In 1901 the population was 1,445,118, showing a further increase of 5 per cent. The land revenue and rates in 1897–98 were Rs.24,06,479, the incidence of assessment being R.1.13.4 per acre; cultivated area, 934,833 acres, of which 206,947 were irrigated, including 104,657 from Government canals; number of police, 729; boys at school (1896–97), 29,022, being 29·2 per cent. of the male population of school-going age; registered death-rate (1897), 21 per 1000. The principal crops are millet, rice, other food grains, and oil-seeds, with a little cotton, sugar-cane, indigo, and tobacco. The South Indian Railway traverses the district for 93 miles.

Tricoupi, Charilaos (1832–1896), Greek statesman, was born at Nauplia in 1832. After studying law and literature in Athens and in Paris, he was sent to London in 1852 as an attaché of the Greek Legation. By 1863 he had risen to be chargé d'affaires, but he aimed rather at a political than a diplomatic career. In 1865, therefore, after he had concluded the negotiations for the cession by Great Britain to Greece of the Ionian Islands, he entered the Greek Chamber of Deputies, and in the following year was made Foreign Minister, at the early age of thirty-four. In 1875 he became Prime Minister for a few months, but had no opportunity even to begin carrying out the policy which he had in mind. This policy was to develop the resources of his country so as to create an army and a fleet, and thus to give Greece the power to acquire a leading place among the nations of south-eastern Europe. It was not until 1882 that he was able to take measures to this end. In that year he became Prime Minister for the third time (his second period of office, two years earlier, had lasted only for a few months), and at once set about the task of putting Greek finance upon a firmer basis, and of increasing the prosperity of the country by making roads, railways, and harbours. He was defeated at the general election in 1885, but in the following year he resumed office, and again took up the labour of economic and financial reform. His difficulties were now increased by the large expenditure which had been incurred for military preparations while he had been out of office, as the result of the union effected between Bulgaria and eastern Rumelia. The Greeks had demanded from Turkey compensation for this shifting of the balance of power, and had prepared to enforce their demand by an appeal to arms. The Great Powers, however, had interfered, and by blockading the Piræus had compelled Greece to remain quiet. Tricoupi, nevertheless, believed that he could in a few years raise the value of Greek paper currency to par, and upon that assumption all his calculations were based. Unfortunately for himself and for his country, he was not able to make his belief good. His dexterity in finance called forth general admiration, and his schemes for the construction of roads and railways met with a certain amount of success. But at last he was obliged to recognize that the warnings offered to him had been sound. Greece could not meet her obligations. Tricoupi tried to make terms with the creditors of his nation, but he failed in this also. The first taxation which he proposed aroused great hostility, and in January 1895 he resigned. At the general election, four months later, he and his party were defeated. He at once retired from public life, and soon afterwards the disease declared itself which eventually proved fatal. He died at Cannes on 11th April 1896. The faults of excessive ambition and of a far too sanguine optimism, which marked Tricoupi's character, could not prevent him from being regarded, even during his lifetime, as the foremost Greek statesman of his time. He was not a favourite with the populace, nor was he beloved so much as respected by his followers. By nature he was reserved—his nickname was "the Englishman"—and he had no sympathy with the arts of the demagogue. But, both in the ranks of his own party and by the nation at large, his abilities and his force of character were unquestioned. It was his misfortune that the circumstances of the time did not allow his wide schemes for the benefit of his country to be carried into effect. (H. H. F.)

Trieste (German, *Triest;* Slovene, *Trst*), the principal seaport of the Austro-Hungarian monarchy, at the north-east extremity of the Adriatic Sea, constituting, with its adjoining territory, a separate Austrian crownland, and

forming the seat of the administration for the Küstenland or littoral; total area, 36 square miles.

The population of the town and district, including 22 suburbs and villages and garrison of 1995 men, was in 1890, 157,466, or 437 per square mile (the population of town and suburbs was 146,556). Of this total 81,973 were female and 75,493 male (a reversal of the relations in the Küstenland as a whole, where the proportion of females to males is 976 to 1000); 77 per cent. Italian, 18 per cent. Slovene, and 5 per cent. German; 95 per cent. Roman Catholic, 3 per cent. Jews, and the Greek Orthodox and Protestant religions, 1 per cent. each. The population, which increases more slowly than the average of Austrian cities, was in 1900. including garrison, 178,672. In 1896 the marriage-rate was 8·15, the birth-rate, 30·92, or excluding still births, 30·16, and the death-rate, 27·73 per 1000. Of the births, 17·83 per cent. were illegitimate. The marriage-, birth-, and death-rates are declining.

Trieste sends 5 members to the Reichsrath, all Italian. The provincial diet, which at the same time performs the functions of municipal council, is composed of 48 Italians and 6 Slovenes. (For education, communications, &c., see KÜSTENLAND.)

In 1888 a monument was erected in commemoration of the 500th anniversary of the connexion of the town with Austria. Trieste, which had been a free port since 1719, and owed its previous prosperity to the release thus granted from hampering legislation, was deprived of that privilege in July 1891. It lost this advantage at a moment when it had to contend with various and increasing difficulties arising from a diversion of traffic towards the Italian and German coasts, the loss of part of the Levant trade through the development of the Orient railway system, and the growing rivalry of the neighbouring Hungarian port of Fiume, whose interests were vigorously promoted by the Transleithan Government. In 1901, however, the efforts to secure a second line of railway connecting Trieste with the interior were at length crowned with success through the adoption by the Reichsrath of the railway programme of the Körber Ministry. This had been recognized by successive Governments as of vital importance for the future of the Austrian export trade, and an important factor in the commercial rivalry between Austria and Germany, the Adriatic and the North Sea. The Government scheme provided for the realization of the two principal competing projects. The first was a line across the Karawanken range (Trieste-Klagenfurt, with a branch to Villach, to be opened in 1905), forming a direct connexion with Bohemia and the northern industrial districts of Austria, calculated to counteract the gravitation of traffic towards the German ports. The second was the Tauern scheme (from Möllbrücken in Carinthia to Schwarzach in Salzburg, through the Gastein valley, to be completed in 1908), the shortest and cheapest route to the Austrian interior, as well as to south Germany, which was expected to raise Trieste to the rank of a first-class harbour. An objection to this line was formerly raised by a section of the Italian element in the town. It would, they contended, bring the Germans to Trieste, and experience had shown that where they once set foot commercially they finished by establishing their political predominance. Another suggestion for reinvigorating Trieste is the construction of a canal connecting it with the Danube.

The total net tonnage of vessels entering and departing in 1871 was 1,900,000. In 1896 it amounted to 3,500,000 tons, the lowest increase of any large European port. In 1890, while still a free port, the total value of the exports and imports was £58,333,000. There was a reduction of £6,416,600 in the following year, but in 1892 trade had begun to recover, the total being £54,583,300, to fall again in 1895 to £52,390,000. Of the entire trade of Trieste, 55 per cent. is with the Levant and the Far East. In 1892 its mercantile fleet consisted of 1267 ships of an aggregate burden of 105,504 tons. These included 110 steamers, of which three-fourths belonged to the Austrian Lloyd, which receives subventions from the state. Fifty-one vessels (5 of them steamers) with a total tonnage of 1660 were built in the docks of the Austrian Lloyd and the Stabilimento Tecnico Triestino, which employ over 3000 hands. Other important industries include the construction of marine steam engines, brewing, tanning, the manufacture of anchors, cables, silk and cotton stuffs, soap, wax, wine, liqueurs, furniture and clothing. The most important natural products are fruit, corn, and oil.

Trifail (Slovene, *Trbovlje*), a commune in the government district of Cilli, in Styria, Austria, near the left bank of the Save and 28 miles east by north of Laibach. It is the centre of an extensive lignite deposit, which yields about 300,000 tons annually. There are also large cement works, and manufactures of chemicals and glass. Population (1890), 8464; (1900), 10,851.

Trikkala (the ancient *Trika*), a town of Greece, capital of the province of Trikkala, 38 miles west of Larissa, and after that town the largest in Thessaly. It has the appearance of a Mussulman town, on account of its mosques (only one of which, however, is in actual use), and it is a centre of trade in wheat, maize, and tobacco. Population (1889), 14,820; (1896), 21,149.

Trincomali, a town and naval station on the north-east coast of Ceylon, 100 miles north-east by north of Kandy. It is no longer the principal capital, having been superseded by Batticaloa, but with its magnificent harbour—one of the five or six greatest natural harbours in the world—it continues to be the headquarters of the admiral commanding on the East Indian station, and there is a garrison of infantry and British artillery. A steamer from Colombo calls weekly with and for passengers and cargo. Average annual rainfall, 62¾ inches; average temperature, 81·2°. Some tobacco, rice, and palms are grown in the district. Population (1900), about 13,000; of district, 28,500.

Tring, a market town and urban district (1894), Hertfordshire, England, in the Watford parliamentary division of the county, 7 miles south-east of Aylesbury. The Rothschild Museum, erected in 1889, contains a very extensive natural history collection, and in a paddock and cages a short distance from the building live animals are kept. Population (1891), 4525; (1901), 4368.

Trinidad, the most southerly, and with the exception of Jamaica the largest, of the British West Indian Islands. Area, 1754 square miles, or nearly 1,123,000 acres. In 1889 Tobago was annexed to Trinidad to form one colony, and since 1899 that island has been incorporated as a ward of the united colony of Trinidad and Tobago. The soil of Trinidad is varied and extremely fertile. Population (1891), 200,028; (1901), 253,250. Of the population a third are East Indians. Of the other two-thirds, the upper classes are mainly of pure or mixed British, French, Corsican, or Spanish blood, while the lower classes are of pure or mixed negro origin. Immigration from India is conducted under Government control, £48,809 being expended for this purpose during 1898. The immigrants numbered 1940 in 1893, 3087 in 1896, and 1292 in 1898. Port-of-Spain, the capital, has a fine harbour, with 7 miles of tramway and 500 miles of telephones; its population in 1900 was 55,000. A system of underground drainage has been constructed. Two other boroughs of importance are San Fernando (7641) and Arima (3653).

The climate is both hot and damp: annual death-rate about 26 per 1000; average rainfall annually about 62 inches at the Botanic Garden. The wet season begins in June and lasts till December, with a short cessation in September. The mean annual temperature is about 80°. In Port-of-Spain, in May, June, September, and October, the shade temperature often reaches 90°; in December and March it often falls below 70° at night.

The principal industries are the cultivation of cacao, sugar-cane-growing, and the manufacture of sugar, rum, and bitters; the growing of coffee, tobacco, cocoanuts, oranges, bananas, and timber (such as mahogany and cedar), dye-woods (logwood and fustic), and balata, rubber-trees; stock-farming, &c. The area under cacao cultivation is nearly twice that of sugar. Cane-farms, as opposed to sugar estates, are on the increase. Large quantities of asphalt are annually exported from the Pitch Lake in La Brea, 90 acres in extent, by a British company which has the exclusive right of digging from the lake, in return for an annual sum (£10,000) and a royalty to the Government, which together in 1898 produced £34,056. The value of the imports in 1900 was £2,500,258; exports, £2,593,475. The trade is principally with the United Kingdom, the United States, France, and Venezuela. The transport trade (almost entirely with Venezuela) represents a quarter of the commerce of the colony. The values of the principal native products and manufactures exported in 1900 were: sugar, with molasses and rum, £552,158; cacao, £978,632; asphalt, £177,460. Large quantities of Tonga beans, the produce of the mainland, are cured in Port-of-Spain, in bond; and as much as £30,000 worth has been shipped in a single year. Out of a total area of 1,123,000 acres, 450,926 acres are unalienated Crown lands. About 205,000 acres are under cultivation.

The revenue in 1900 was £698,939; expenditure, £659,079; public debt, £918,472. About thirty-four steamers call at Trinidad per month. Port-of-Spain is in direct communication with Southampton. The shipping entered and cleared in 1900 had a total tonnage of 1,178,494, of which 591,102 was British. The island is not well furnished with roads, the total mileage being 193. There are 90 miles of railway, besides several miles of steam, electric, and mule tramways; and 166 miles of internal telegraphs.

Places of worship are owned as follows:—Roman Catholic, 60; Anglican, 51; Baptist, 16; Wesleyan, 13; Presbyterian, 8 (and 59 chapels). The bishopric of Trinidad forms part of the West Indian Province of the Church of England. The 239 elementary schools are of two kinds: (1) 56 Government schools, which are secular; (2) 183 denominational schools, aided by grants. In 1898 there were 9810 children on the rolls of the former and 18,056 on those of the latter. Fees are paid. More than a quarter of the assisted schools are managed by a Canadian mission. Agriculture is a compulsory subject. For higher education there are the Queen's Royal College (secular), and its affiliated institutions, St Mary's College (Roman Catholic), and a school managed by the Canadian mission. Attached to these are four exhibitions of the value of £150 a year, tenable for three years at an English university, granted annually. There are also many private schools. English is generally spoken in the towns, and in some of the districts. In the country parts of the north, and generally in the cacao-growing districts, the common language is a French patois. Over some small areas Spanish is still spoken. There are good hospitals at Port-of-Spain (320 beds) and San Fernando (120 beds), 8 district hospitals, a segregation hospital, and a lunatic asylum. There is no poor law. There is no regular military force in the colony. There are three volunteer corps—light horse, garrison artillery, and light infantry—making a total force of 697 men. The police force numbers 555 officers and men. There is a Legislative Council consisting of the governor with 9 official and 11 unofficial members all appointed by the Crown.

(F. Cu)

Trinidad, an uninhabited island in the South Atlantic, 680 miles east of the coast of Espirito Santo, Brazil, in 20° 30′ S. and 29° 30′ W., 4 miles long by 2 broad. It is of volcanic formation, and has fertile springs of fresh water. As a possible coaling and telegraph station in mid-ocean, it has formed a subject of contention between Brazil and Great Britain. The dispute was settled in favour of Brazil, which claimed on the ground of its discovery by Tristan da Cunha early in the 16th century, while Great Britain relied on its occupation by the astronomer Halley in the name of England in the year 1700. About 30 miles farther east are the three islets of Martin Vaz, so named from the Portuguese mariner who discovered them about 1510.

Trinidad, a city of Colorado, U.S.A., capital of Las Animas county, on the Purgatory river, at the foot of the Raton Mesa, in the southern part of the state. It has a hilly site, on which it is regularly laid out, and has a good water-supply. It is on three railways—the Denver and Rio Grande, the Colorado and Southern, and the Atchison, Topeka, and Santa Fé. It is in a stock-raising region, and near the rich coal-fields of southern Colorado. It has railway works and coking ovens, and handles large quantities of coal. Population (1895), 5982; (1900), 5345, of whom 659 were foreign-born and 125 negroes.

Trinidad, a town near the southern coast of Cuba, about 35 miles south-east of Cienfuegos, and 3 miles from its seaport, Casilda, which lies due south. It is one of the original seven cities of Cuba founded by Lieutenant-Governor Diego Velasquez in 1513. Sugar and honey are exported. The town, which is surrounded by high mountains, is mediæval in aspect, but contains some fine buildings. The scenery, which is unexcelled, and the climate, which is considered to be the healthiest in Cuba, make the place a favourite resort for natives and foreigners. Population (1899), 11,120.

Tripoli, a Turkish vilayet (regency) of North Africa, extending from the Mediterranean to the Sahara Desert in 23½° N. Much fresh light has been thrown on its physical, ethnical, and economic relations by Haimann, Fournel, Cowper, Borsari, and other observers. Tripoli does not form a geographical unit, but comprises at least five distinct regions—Tripoli proper, the Barca plateau (*Cyrenaica*), the Aujila oases, Fezzan, and the oases of Ghadames and Ghat—which with the intervening sandy and stony wastes occupy the whole space between Tunisia and Egypt, extend from the Mediterranean southwards to the Tropic of Cancer, and have a collective area of about 400,000 square miles, with a population variously estimated at from 1,200,000 to 1,600,000. The regency has remained almost untouched by the political changes by which the map of Africa has been so profoundly modified since the early 'eighties. Towards the south and east the frontiers still remain undefined. But on the west side, where the country is conterminous with Tunisia, the conventional line laid down by agreement with France in 1886 was more accurately determined in 1892, when the terminal point on the Mediterranean was shifted from Borj-el-Biban to the Ras Ajir headland, 18 miles to the south-east, in 33° 12′ N. and 12° E. From this point the line runs southwards along the Wed Magla and across the El Erg dunes in such a way as to leave Ghadames to Turkey. Beyond that oasis the line has not been traced, because the southern region as far as Ghat, which is recognized as belonging to the vilayet, is held by the still independent Azjar (Tuareg) nomads.

Physical features.

For some distance east of Tunis the seaboard is low and sandy, and is often regarded as a part of the Sahara, which, however, begins only some 80 miles farther south, beyond the Jebels Nefusi, Yefren, and Ghurian (Gharian). The "Jebel," as this system is locally called, terminates eastwards in the Tarhona heights of the Homs (Khoms) coast district, has a mean altitude of about 2000 feet, and culminates in the Takut volcano (2800 feet), nearly due south of the capital. It is not, however, a true mountain range, but rather the steep scarp of the Saharan plateau, which encloses southwards the Jefara coast plains, and probably represents the original coast-line. The Ghurian section is scored in places by the beds of intermittent coast streams, and on its lower slopes is clothed with a rich sub-tropical vegetation. South of these escarpments, which Cowper calls the "Tripoli chain," the vast Hammada el-Homra, the "Red Hammada," an interminable stony tableland covering some 40,000 square miles, occupies the whole space between Tripoli proper and the Fezzan depression. The now uninhabited and waterless Hammada formerly drained through several large rivers, such as the Wadys

Targelat (Uani, Kseia), Terrgurt, Sofejin, Zemzem, and Bel, north-eastwards to the Gulf of Sidra (*Syrtis major*). Southwards the tableland is skirted by the Jebel Welad Hassan, the Jebel es-Suda, the Jebel Morai-Yeh, and other detached ranges, which have a normal west to east trend in the direction of the Aujila oases, rising little above the level of the plateau, but falling precipitously towards Fezzan. The Jebel es-Suda ("Black Mountains"), most conspicuous of these ranges, with a mean altitude of 2800 feet, takes its name from the blackened aspect of its limestone and sandstone rocks, which have been subjected to volcanic action, giving them the appearance of basalt. Eastwards this range ramifies into the two crescent-shaped chains of the Harúj el-Aswad and Harúj el-Abiad ("Black" and "White" Harúj), which rise some 700 feet above the Red Hammada, and enclose an extensive Cretaceous plateau, which has never been visited since it was crossed by Hornemann in 1798. Beyond the barren Ghadama district in the extreme north, the dreary aspect of the wilderness is broken by several productive tracts under grass, corn, and date-palms, and even containing some permanent reservoirs in the beds of the Wadys Sofejin and Zemzem, where the plateau falls from a mean height of 2000 feet to 1000 and 530 feet respectively. But it again rises rapidly southwards to a somewhat uniform level of 1600 or 1700 feet, and here the main caravan route from Tripoli to Murzuk and Lake Chad traverses for a distance of fully 130 miles a monotonous region of sandstone, underlying clays, marls, gypsum, and fossiliferous silicious deposits. In its northern section this part of the Hammada, as it is locally called in a pre-eminent sense, is relieved here and there by a few patches of herbage, scrub, and brushwood, with even a little water left in the rocky cavities by the heavy showers which occasionally occur in this almost rainless desert.

North-eastwards the Neddik pass over the Jebel Morai-Yeh leads down to the remarkable chain of low-lying oases, which, from the chief member of the group, is commonly called the Aujila depression. Collectively the oases present the aspect of a long winding valley, which is enclosed on the north side by the southern escarpments of the Barca plateau, expands at intervals into patches of perennial verdure and shallow saline basins, and extends from the Wady el-Fareg, near the Gulf of Sidra, through the Bir Rassam, Aujila, Jalo, Faredgha, and Siwah oases, to the Natron lakes and the now dried-up branch of the Nile delta known as the Bahr bilá-Má ("waterless river"). The whole region presents the aspect of a silted-up marine inlet, which perhaps in Pliocene times penetrated some 300 miles south-eastwards in the direction of the Nile. Nearly all the fossil shells found in its sands belong to the fauna now living in the Mediterranean, and Siwah is still actually 98 feet below sea-level. This is true also of its eastern extensions, Sittra (80) and the Birket el-Kerun in the Fayum (141). But Aujila and Jalo stand, on the contrary, 130 and 296 feet respectively above sea-level, so that the idea at one time entertained by Rohlfs of transforming the chain of oases into a marine gulf, and thus converting the Barca plateau into an island or peninsula in the midst of the Mediterranean waters, and in fact flooding the Libyan desert, must share the fate of Rudaire's equally visionary scheme in respect of the Algerian Sahara.

The Aujila depression.

The Barca plateau, which falls in terraces down to the Aujila depression, and presents an unbroken rampart of steep cliffs towards the Mediterranean, is by far the most favoured region of the vilayet. Its many natural advantages of climate, soil, and vegetation had already in remote times attracted numerous Egyptian settlers to *Barke* (later Ptolemais) and other points. But these were afterwards replaced by Greek colonies, the oldest and most famous of which was the Dorian settlement of *Cyrene*, dating from about 630 B.C. From this place the whole region took the name of Cyrenaica, and was also known as *Pentapolis*, from its "five cities" of Cyrene, Apollonia, Arsinoe, Berenice, and Barke. The elevated plateau of Cyrenaica, which encloses the Gulf of Sidra on the west, is separated southwards by the Aujila depression from the Libyan desert, and projects northwards far into the Mediterranean, might seem, like the Atlas region in the extreme west, to belong geologically rather to the European than to the African mainland. It has a mean altitude of considerably over 2000 feet, and in the Jebel Akhdar ("Green Mountains") attains a height of nearly 3500 feet. Eastwards the Barca uplands merge gradually in the less elevated Marmarica plateau, which nowhere rises more than 1800 feet above sea-level, and disappears altogether in the direction of the Nile delta.

The Barca plateau.

South of the Aujila depression the land rises steadily to a height of nearly 1200 feet in the *Kufra* oases, which lie to the north of the Tropic of Cancer and due east of Fezzan, of which they may be regarded as a geographical dependency. The group consists of five distinct oases in the heart of the Libyan desert—Taizerbo, Zighen, Bu-Zeima, Erbena, and Kebabo—which extend for a distance of 200 miles north-west and south-east, and have a collective area of 7000 square miles and a present population of 6000 or 7000 Arabo-Berber nomads. Good water is obtained in abundance from the underground reservoirs, which lie everywhere within a few feet of the surface, and suffice to support over a million date-palms. Kufra, that is, "Infidels" (in reference to the now extinct pagan Tibu aborigines), is a great stronghold of the Senúsiya brotherhood, whose *zawya* (convent) at Jof, in Kebabo, ranks next in importance to that of Jarabub, their chief station in the Sahara. This circumstance, together with the great fertility of the group and its position midway on the caravan route between Cyrenaica and Wadai, imparts exceptional political and commercial importance to these oases.

The Kufra oases.

Fezzan, the ancient *Phazania*, appears to have been the chief centre of the Garamantes, whose empire was overthrown by the Romans in the reign of Augustus. A stone monument near their capital *Garama* (now Jerma) marks the southernmost limit of the Roman dominion in the interior of the continent. The Romans were succeeded in the 7th century by the Arabs, who maintained their independence till the 16th century, when Fezzan was attached to the Turkish vilayet of Tripoli. The Hofra ("ditch"), as it is called, does not form a continuous fertile tract, as might be supposed from the large space on most maps coloured green and labelled "Fezzan," but rather consists of a monotonous sandy expanse somewhat more thickly studded with verdant isles than the surrounding wastes. The oases are numerous, especially in the district of the capital, Murzuk, and farther north, in the Wady Lajâl, a long narrow valley which trends north-east in the direction of the White Harúj, and the western section of which—the Wady Gharbi—is the most fertile tract in the whole of Fezzan. Here are several perennial springs, and even lacustrine basins with cornfields and date-groves, enlivened by flocks of doves and hoopoes. One of these basins, the saline Bahr el-Dud ("Sea of Worms"), has an extent of no less than 600 square miles, with a depth, according to Vogel, of at least 26 feet. Here stood *Old Jerma* (Garama), capital of the Garamantes; and of the Roman province, later replaced by *New Jerma*, a little farther north. Murzuk, the present capital, dating from about the 12th century, is less favourably situated, lying farther east near the Wady Sherkiya wells, where the Hofra falls to its lowest level, about 600 feet above the sea. It has a mixed population of about 7000 Arabs, Tuaregs, and Negroes, who are almost entirely dependent on the caravan trade between Sudan and Tripoli.

Fezzan.

From Murzuk a beaten track leads across a stony waste, west by south, to the oasis of Ghat; and it was at the Sharaba wells, on this route, that Miss Tinné was murdered by the Tuaregs in 1869. East of Murzuk follow the oases of Traghen, Zuila, and Temissa, and far to the south-east Wau el-Kebir, discovered by Beurmann in 1862. Southwards the Hofra again rises to a height of 2000 feet, and in this direction lies the oasis of Gatron, followed by Tejerri on the verge of the desert, which marks the southern limit of the date and the northern of the dum palm. Beyond Tejerri the Saharan plateau rises continuously to the Tibesti highlands, from which it seems evident that Fezzan is a true depression, like Lake Chad an old lacustrine basin without seaward outflow, and flooded at a time when the Sahara enjoyed a moister climate than at present.

Ghat stands 2400 feet above the sea, on the Wady Aghelad in the Igharghar basin, and consequently belongs, not to the Fezzan depression, but to the Saharan plateau. The Aghelad, or "Passage," trends north to the Iasawan valley along the east foot of the Tasili plateau, that is, the divide between the waters which formerly flowed north to the Mediterranean, west to the Atlantic, and south to the Niger and Chad basins. Ghat, which is skirted eastwards by the Akakus range, forms a sandy plain dotted over with clumps or groves of date-palms. In the centre is an open space where is held a great annual fair, and to this, combined with its position on one of the caravan routes across the desert, the oasis owes all its importance. There is a collective population of perhaps 10,000, nearly all Ihajenen Tuaregs, about half of whom are concentrated in the town of Ghat, which appears to be a relatively modern place, successor to *Rapsa*, a great commercial centre and military station under the Roman empire.

Ghat.

Ghadames, on the contrary, is a very old place, being the *Cydamus* of the Garamantes, the capture of which by Cornelius Balbus led to the overthrow of their empire. The oasis, which stands on the Cretaceous Tinghert plateau, 300 miles south-west of Tripoli, and 1200 feet above the sea, is enclosed by a circular rampart over 3 miles in circumference. The town, which occupies the south-west corner of the enclosure, has a population of about 7000, forming distinct ethnical and even hostile groups of Arabs, Berbers, and Negro freedmen, all following their own customs and speaking their own language, but using Berber as the medium of general intercourse. Owing to some perennial springs and artesian wells, the oasis is very productive, yielding an abundance of dates, figs, apricots, and vegetables, besides some wheat, barley, and millet. It occupies a highly advantageous position at the converging-point of several caravan routes, and has extensive trading relations with the markets of Tripoli, Tunis, and Sudan. The Turkish authority is little more than nominal, and the French masters of Tunis are looking forward to the peaceful occupation of Ghadames in the near future.

Ghadames.

The explorations of Duveyrier, Largeau, Von Bary, and Cowper have shown that Tripoli was not only inhabited by primitive man, but was the seat of a flourishing Neolithic culture, comparable to and in many respects resembling that of Iberia, Brittany, and the British Isles. As in other parts of Mauritania, many now arid and uninhabitable wastes are strewn with monolithic and other remains, which occur in great variety of form and in vast numbers, as many as 10,000, chiefly of the menhir type, having been enumerated in the Mejana steppe alone. All kinds of megalithic structures are found—dolmens and circles like Stonehenge, cairns, underground cells excavated in the live rock, barrows topped with huge slabs, cup stones, mounds in the form of step pyramids, and sacrificial altars. Most remarkable are the "Senams," or trilithons of the Jebel Msid and other districts, some still standing, some in ruins, the purpose of which has not been determined. They occur either singly or in rows, and consist of two square uprights 10 feet high standing on a common pedestal and supporting a huge transverse beam. In the Terrgurt valley "there had been originally no less than eighteen or twenty megalithic trilithons in a line, each with its massive altar placed before it" (Cowper). There is reason to believe that the builders of these prehistoric monuments are represented by the Hamitic Berber people who still form the substratum, and in some places the bulk, of the inhabitants of Tripoli proper. But even here the Berbers have for the most part been driven to the Ghurian and Tarhona uplands by the Arab nomads, who now occupy the Jefara flats about the capital, and are in almost exclusive possession of Cyrenaica, Marmarica, and the Aujila oases. In Fezzan the Saharan Berbers (Tinylkum Tuaregs) are still dominant, but are here largely intermingled with Negro or Negroid intruders from Sudan. But even in the uplands many of the Berbers have been Arabized, and Cowper describes those of the Tarhona heights as even "pure-bred Arabs." Other early intruders are the Jews, some of whom arrived from Egypt in the time of the Ptolemies, and are still found leading the life of troglodytes in the limestone caves of the Ghurian escarpments. They are also numerous in the large towns, where the population is further diversified by the presence of Turkish officials and garrison troops, of Maltese, Italian, and other South European traders and artizans.

Inhabitants past and present.

On the other hand, no trace can now be detected either of the Greeks who colonized Cyrenaica in the 7th century B.C., or of the Phœnicians who at a still earlier date founded the three great cities of Œa, Sabrata, and Leptis Magna, from which the western region projecting seawards between the two Syrtes took the name of Tripolitana. Later, when Œa, which stood between the two others, was made the capital of the province, it was called Tripolis, the "Three Cities," as it were, rolled into one, and this name it has retained since Roman times, being now distinguished from the Tripolis of Syria as West Tripolis, the *Tarabulus el-Gharb* of the Turks and Arabs. TRIPOLI, still the capital of the province, is thus one of the oldest places in the world, and no doubt owes its stability in large measure to its position over against Sicily at the northern terminus of three great historic caravan routes, one of which runs due south to Lake Chad through Fezzan and Bilma, that is, across the narrowest part of the Sahara; another runs south-west through Ghadames to Timbuktu, and the third south by east through Sokna to Wadai and Darfur. The city, which has a population (1900) of 30,000 within its crumbling walls, besides an equal number of semi-nomad Arabs and Negro freedmen in the Meshiya district round about the ramparts, occupies the south-west side of a crescent-shaped bay partly sheltered by a chain of low reefs from the northern winds. The harbour or roadstead has a depth of about 20 feet, but owing to a dangerous bar is inaccessible to vessels drawing over 14 feet. In 1899 the port was visited by over 600 ships of 200,000 tons, of which 70, of 51,000 tons, were British. In Barca the only important centre of population is *Benghazi*, the ancient *Berenice*, at the southern extremity of a headland which formerly enclosed a spacious natural haven on the north-east side of the Gulf of Sidra. But the harbour has been partly filled up by the ruins of a large fortress, and is now inaccessible to vessels drawing over 6 or 7 feet. Benghazi has a mixed population of about 15,000 Arabs, Berbers, Jews, and Negroes. East of Benghazi is the exposed roadstead of *Derna*, which was occupied by the Americans in 1815. Nothing has been done to complete the harbour works begun by them; but it is now proposed to restore the port of *Marsa-Susa*, the ancient *Apollonia*, which lies under the Ras Sem headland, and was formerly much frequented as the emporium of the neighbouring city of Cyrene (Grenna). The Government has displayed much activity in this fertile and healthy district, to which have been removed many of the Turkish inhabitants of Crete dissatisfied with the present relations in that island. Nearly the whole of the foreign exchanges pass through the ports of Tripoli and Benghazi, where the total imports were valued in 1900 at £499,500, and the exports at £418,500. Of the imports, chiefly cottons, silks, sugar, and flour, £123,000 were British; while the exports to Great Britain, chiefly alfa-grass, sponges, ostrich feathers, wool, skins, and ivory, were valued at £158,000. The caravan trade across the Sahara with Sudan has suffered a severe blow by the opening of new routes to the Atlantic through British and French territories (Niger, Benue, and Senegal routes). Nevertheless the total exchanges rose from £143,000 in 1897 to nearly £200,000 in 1898. The convoys bound for the interior of the continent are laden chiefly with English cottons, Venetian beads, Bohemian glass, silks, paper, tea, and sugar, and return with ostrich feathers, dressed goat-skins, and ivory. Some of these wares reach the capital from Wadai by the Benghazi route. (For climate, natural history, administration, and other details, see TRIPOLI in the ninth edition of this work.)

Towns and trade.

Tripoli, now *Tarábulus*, the chief town of a sanjak of the same name in the Beirut vilayet in Syria, situated about 2 miles inland from its port, el-Mina. The population, including el-Mina, amounts to 30,000 (Moslems 24,000, Christians 6000). In 1900 the exports were valued at £607,700 and the imports at £311,800, the principal exports being silk thread, cereals, lemons and oranges, wool, sponges, and soap.

Tristan da Cunha, a group of three islands belonging to Great Britain, situated in the South Atlantic, 1500 miles south-west of St Helena. Annexed in 1816, the garrison was removed in the next year. Three men, of whom one was married and had ten children, remained behind, and from these, together with settlers from whaling ships, the present population is derived. It consisted in 1897 of 64 persons, against 109 in 1880. In spite of healthy surroundings and of naturally fine physique, the race appears to be deteriorating from want of infusion of fresh blood. What government there is is carried on under a patriarchal system. The question of education presents great difficulties. It has been proposed that the children should be sent to Cape Colony to receive their education. The climate, though very windy and rainy, is healthy, averaging from 68° in summer to 55° in winter. Tristan da Cunha is visited once a year by a British war-vessel.

Trivandrum, or TREVANDRUM, a town of southern India, capital of the state of Travancore, situated about 2 miles from the sea-coast. Population (1891), 27,887. The best houses and chief public buildings stand on hilly terraces above. There is a cantonment for the Nair brigade. The town contains the

Maharaja's college, a Sanskrit college, a high school, a school for girls, and an industrial school of arts, a hospital and medical school, an observatory and museum. There is little trade, but it makes a speciality of wood-carving.

Trochu, Louis Jules (1815–1896), French general, was born at Palais, near Belleisle, Morbihan, on 12th March 1815. Educated at St Cyr, and at the Staff Corps Practical School, he received a commission in the army in 1837, was promoted lieutenant in 1840, and captain in 1843. He served as a captain in Algeria under Marshal Bugeaud, who, in recognition of his gallantry in the battles of Sidi Yussuf and Isly, made him his adjutant and entrusted him with important commissions. He was promoted major in 1845, and lieutenant-colonel in 1853. He served with distinction throughout the Crimean campaign, first as colonel and aide-de-camp to Marshal St Arnaud, and then as general of brigade (Commander, Legion of Honour, and general of division). He again distinguished himself in command of a division in the Lombardy campaign of 1859 (Grand Cross, Legion of Honour). In 1866 he was employed at the Ministry of War in the preparation of army reorganization schemes, and he published anonymously in the following year *L'Armée Française en 1867*, a work inspired with Orleanist sentiment, which ran through ten editions in a few months and reached a twentieth in 1870. This brochure brought him into bad odour at Court, and he left the War Office on half-pay, but was afterwards selected to command the Toulouse division. After the disasters in the war with Germany in 1870, he was appointed (17th August) governor of Paris and commander-in-chief of all the forces destined for the defence of the capital, including some 120,000 regular troops, 80,000 mobiles, and 330,000 National Guards. He worked energetically to put Paris in a state of defence. At the revolution of the 4th September, he became president of the Government of National Defence in addition to his other offices. His "plan" for defending the city raised expectations doomed to disappointment; the successive sorties made on the besieging Germans were unsuccessful, and having declared in one of his proclamations that the governor of Paris would never capitulate, when capitulation became inevitable he resigned the governorship of Paris on 22nd January 1871 to General Vinoy, retaining the presidency of the Government until after the armistice in February. He was elected to the National Assembly by eight departments, and sat for Morbihan. In October he was elected president of the Council General for Morbihan. In July 1872 he retired from political life, and in 1873 from the army. He published, in 1873, *Pour la Vérité et pour la Justice*, in justification of the Government of National Defence, and in 1879 *L'Armée Française en 1879, par un officier en retraite*. He died at Tours on 7th October 1896. (R. H. V.)

Troitskosavsk, a district town of Russia, in the province of Transbaikalia, 2¼ miles from Kyakhta and 2½ miles from the Chinese frontier. When the main trade was transferred to Kyakhta, the town fell into decay for a period, but it has already begun to revive, and was made the chief town of a district in 1901. Population (1897), 9213.

Trombetas. See AMAZON.

Tromsö, a seaport town of Norway, capital of the county of Tromsö, in 69° 38′ N. It has a trade, valued at £130,000 to £170,000 per annum, in the export of whale and seal oil (£34,500), and fish (£37,000); and in the import of coal (£25,250), textiles, salt, grain, and flour. Mean temperature of year, 36·4° Fahr.; February, 25°; July, 51·8°. Population (1875), 5409; (1900), 6955.

Trondhjem, a seaport town and bishop's see of Norway, on the west coast, and south side of Trondjhem Fjord, 349 miles by rail north of Christiania, and 531 by rail north-west of Stockholm *viâ* Östersund. The restoration of the choir of the cathedral was finished in 1890; that of the north and south transepts in 1900. The bishop's palace has been converted into barracks and arsenal, and there are a new fisheries museum and industrial art museum. The city's commerce has grown with the prosperity of the Roros and Sulitelma mines, and with the opening of the railway from Östersund, increasing from £747,000 in 1882 to £1,226,500 in 1892 and £1,903,000 in 1899. Of this about three-fifths is for imports—coal, grain and flour, groceries, salt, and machinery; the remainder being for exports—timber, wood-pulp, fish, butter, copper, iron, and pyrites. The bulk of the imports comes from Great Britain, and a large portion of the exports passes overland by rail into Sweden. In 1900 the port was entered by 484 vessels of 277,743 tons, as compared with 230 vessels of 111,100 tons in 1886. The industries embrace saw-mills, wood-pulp factories, fish curing factories, machine shops, and a ship-building yard. Population (1891), 29,162; (1900), 38,156.

Troon, a police burgh (1896), seaport, railway station, and watering-place of Ayrshire, Scotland, 6 miles north by west of Ayr. It has the best natural harbour in the county, with over a mile of quayage, a breakwater 3000 feet long, and two graving docks. In 1888, 2500 vessels of 251,514 tons entered; in 1898, 1573 of 252,150 tons. The principal article of import is iron ore, and coal and pig-iron are the chief exports, 449,767 tons of the former having been shipped in 1898. Shipbuilding is the principal industry. The municipality is very progressive, and controls waterworks (1895) and gasworks, both of which are being largely extended. Two golf-courses attract many visitors. Population (1891), 3315; (1901), 4696.

Troppau (Polish, *Opava*; Czech, *Opava*), the capital of Austrian Silesia, situated on the Oppa river, close to the Prussian frontier, 37 miles north-east of Olmütz. The industries comprise the manufacture of hats and fezzes, jute fabrics, tiles, &c., beer, spirits, and liqueurs. Population (1890), 22,867; (1900), 26,725, including a garrison of 2154 men.

Trossachs, The, a characteristic Highland district in the south-west of Perthshire, Scotland. Strictly speaking, it is a narrow, beautiful-wooded glen or defile in the upper valley of the Teith, extending from Loch Katrine on the west to Loch Achray on the east, a distance of only about a mile. On the south-west the pass is shut in by the steep green slopes of Ben Venue (2393 feet), and on the north-east by the bolder and more precipitous Ben A'an (1750 feet), backed by two hills of much greater altitude—Ben Vorlich (3224 feet) and Ben Ledi (2875 feet). The region, which is one of great natural charm, owing to its blending of wood, water, rock, and hill, was made famous by Scott's poem *The Lady of the Lake* (1810). From the lovely Ellen's Isle, near the east end of Loch Katrine, all the way to Callander, every mile recalls associations of the stirring poem—Brig of Turk, Glen Finglas, Lanrick Mead, Coilantogle Ford, Bochastle, Pass of Leny, Strathyre, St Bride's. And the publication, seven years later, of *Rob Roy* awakened equally romantic, though less poetic, associations of

another kind—namely, those which cluster about the "broken" clan of the MacGregors, as the Braes of Balquhidder, Rob Roy's cave, Portnellan, Glengyle, Glenfalloch, Aberfoyle, Killearn, Glen Fruin, Inversnaid, and so forth. In the wider usage of the term, the Trossachs embraces about a dozen lakes altogether, each as a rule lying amid grassy heath-clad hills 1000 to 3000 feet and more in altitude. The names of these lakes and other particulars regarding them are contained in the annexed table :—

Loch.	Alt. in feet above sea-level.	Length in miles.	Max. breadth in miles.	Max. depth in feet.	Mean depth in feet.	Area of loch in acres.	Area of drainage basin in sq. miles
Lubnaig .	405	4		146	42¾	614	35
Voil . .	414	3½		98	41	561	35⅓
Doine . .	414	1		65	33	138	
Vennachar	270	4		111	42½	1030	28½
Drunkie .	416	1		97	36	138	2⅕
Achray .	276	1¼		97	36	207	7
Katrine .	364	8	1	495	199	3059	37½
Ard . .	105	2¼		...	...	...	...
Chon . .	290	1¾		...	...	...	..
Arklet .	455	1		67	24	210	5⅓
Lomond .	23	22	4½	630	66–120	17,420	...

Except for the lower (eastern) extremity of Loch Vennachar, all these lakes lie just within the Highland line, that is, immediately west of the great geological fault which stretches in a north-east to south-west direction right across Scotland, from the coast of Kincardineshire to the Firth of Clyde, and in a region which is seamed with secondary faults that branch off from the main fault at various angles. The district as a whole is built up of the crystalline schists which characterize the Highlands, the rock formations being mostly hard conglomerates and pebbly grits. Indeed, it was the hard coarse grits of Ben Ledi which originally dammed up the east end of Loch Katrine, and made the lovely pass of the Trossachs which links that lake with Loch Achray. As the table above clearly indicates, every one of these lakes is long and narrow, and relatively of no great depth, though the two largest do indeed go down below sea-level, namely, Loch Lomond to the extent of over 600 feet, and Loch Katrine 500 feet. From these circumstances, coupled with the general indications of their physical surroundings, it is pretty certain that they owe their origin, or at any rate their present shape and extent, to glacial action. In most cases each loch consists of but a single basin, which is scooped out to its greatest depth in a narrow trough along the middle; but in Lochs Vennachar and Katrine the maximum depth is found in each case towards the east, and in Loch Voil, quite exceptionally, at the western end. The lake last named and its neighbour, Loch Doine, were at no very distant period connected, and obviously formed one sheet of water. Two of the lakes, however, namely, Loch Lubnaig and Loch Drunkie, have each two distinct basins, all more than 50 feet in depth throughout. Loch Lomond, which is not only the largest of the Trossachs lakes—in fact, it is the largest lake in Scotland—but is also esteemed the most beautiful, is divided into three distinct basins, separated by two sublacustrine barriers—one, at Rowardennan, coming to within 6 feet of the surface, and the other, at the island of Eilean Vow, not far from the head of the loch, only 48 feet below the surface. The greatest depth occurs in the middle basin between Tarbet and Inversnaid, namely, 630 feet. The lake is, however, widest at its southern end, where its charm is greatly enhanced by about thirty green islets, the whole framed in a setting of soft green hills, which, in Smollett's words (*Humphrey Clinker*), "display a sweet variety of woodland, cornfield, and pasture . . . while the prospect terminates in huge mountains covered with heath." At its northern end the lake narrows to a mile and even less in width, and the enclosing hills not only wear a barer aspect, but draw together closer about the loch. About midway up, the chain of hills which fence in the lake on the east reach their culminating point in Ben Lomond (3192 feet). This, together with its sister hills on the north and south, forms the watershed of the middle belt of Scotland; on the east the Forth and its affluent, the Teith (which flows out of Loch Katrine and through Lochs Achray and Vennachar), convey the drainage to the North Sea, and on the west the Leven carries the surplus water of Loch Lomond into the Clyde, and so into the Atlantic. Nearly opposite Ben Lomond, on the west side of the lake, a low narrow neck of land between Arrochar and Tarbet is all that separates Loch Lomond from the sea-fjord of Loch Long, and a subsidence of less than 40 feet would convert the former into what it no doubt was in prehistoric times, namely, an actual arm of the sea. Loch Lomond is well stocked with fish—sea-trout, lake-trout, pike, perch, and occasionally salmon, and formerly it also yielded flounders, eels, and the fresh-water herring (*powan*). There are also numbers of trout in Lochs Katrine, Vennachar, Lubnaig, and most of the smaller lakes, besides salmon, char, perch, and pike. The annual rainfall throughout the Trossachs region ranges from 53·7 inches on the west face (1800 feet) of Ben Ledi to 115·1 inches at Ardlui (50 feet) at the head of Loch Lomond. This matter has acquired special importance since 1855, and in an even much greater measure since 1884, owing to the city of Glasgow's schemes for drawing its water-supply from Loch Katrine. In consequence of the execution of these schemes the level of Loch Katrine has been raised 4 feet above its normal summer level, and may be raised yet another 5 feet; while the level of Loch Vennachar may be raised 5¾ feet and Loch Drunkie as much as 25 feet. Further authorization has been obtained to tap Loch Arklet, and convert it into a larger gathering basin by raising its level 25 feet; and in case still greater supplies shall be necessary, it would probably be found feasible to draw upon Lochs Voil and Doine, which lie 50 feet above Loch Katrine, and upon Loch Lubnaig, which lies 41 feet above the latter, the water being in both cases conducted by means of aqueducts bored through the intervening hills. (See further under GLASGOW.)

The Trossachs are approached by coach from Callander station on the Stirling–Oban branch of the Caledonian Railway, and by coach from Aberfoyle station on the North British Railway, by steamer up Loch Lomond, and since 1894 by the West Highland Railway, which runs along the west side of Loch Lomond from Tarbet. In summer steamers ply on Loch Katrine, communicating with the rail at Balloch (southern end) and with rail or coach at Ardlui (northern end), and calling at Luss, Balmaha, Rowardennan, Tarbet, and Inversnaid.

(J. T. BE.)

Trouville-sur-Mer, a town, arrondissement of Pont l'Évêque, department of Calvados, France, 24 miles in direct line north-east of Caen, with terminal station (Trouville–Deauville) on railways from Caen and Pont l'Évêque. Besides trawl-fishing and the provisioning of ships, in which Deauville is also engaged, Trouville has boat-building, rope, and briquette works. The port, shared with Deauville, comprises in addition to the commercial harbour and the fishing quay (2132 feet long) a half-tide dock 230 feet long with 750 feet of quayage, connected with the railway. A reservoir, excavated in the bed of the river above the floating basin, is connected with the latter by siphons. The London and South-Western Railway Company have a daily steamboat service to Trouville in connexion with their Southampton and Havre boats. Passengers arriving from Havre by steamer in 1900 numbered 110,850, and the departures 110,977. The number of vessels entered, 1900, was 143 of 48,718 tons (from England, 129 of 42,717 tons), cleared, 139 of 49,947 tons (to England, 134 of 46,480 tons). Including coasting, the total port traffic amounted to 133,228 tons. The fisheries employed in the same year 100 ships with 385 men. Population (1891), 5627; (1901), 6137. Deauville (1901), 2857.

Trowbridge, a market town in the Westbury parliamentary division of Wiltshire, England, 8 miles south-east of Bath, on the Great Western Railway. Modern erections include a town hall and a high school. Population (1891), 11,901; (1901), 11,526.

Troy, represented now by important ruins on and about the mound of Hissarlik, situated in the north-west angle of Asia Minor, about 3½ miles both from the Dardanelles and from Yeni Koi, which lies on the Ægean coast north of Besika Bay. The famous academic dispute concerning the precise site, which began about A.D. 160 with Demetrius of Skepsis, and was still being maintained in the ninth edition of this Encyclopædia (*s.v.* Troad), may now be regarded as settled. After the full demonstration, made in 1893, that remains of a fortress, contemporary with the great period of Mycenæ, and larger than the earlier acropolis town, first identified by Schliemann with Ilios, exist on the mound of Hissarlik, no reasonable person has continued to doubt that this last site is the local habitation of the Homeric story. The rival ruins on the Bali Dagh have been shown to be those of a small hill fort which, with another on an opposite crag, commanded the upper Menderé gorge. It is inconceivable that this fort should have been chosen by poets, generally familiar with the locality, as the scene of the great siege, while in the plain between it and the sea there had lain from time immemorial, and lay still in the Mycenæan age, a much more important settlement with massive fortified citadel.

No site in the Troad can be brought into complete accordance with all the topographical data to be ingeniously derived from the text of Homer. Indeed, it would be little short of miraculous if consistent accuracy in every small detail of the locality were preserved in poems composed and combined as were the cantos of the *Iliad*. The hot and cold springs that lay just without the gate of "Troy" (*Il.* xxii. 147) are no more to be identified with Bunarbashi, which wells out more than a mile from the Bali Dagh ruins, than with the choked conduits, opened by Schliemann in 1882, to the south of Hissarlik. But the broader facts of geography ought to be, nay are, recognizable in the modern plain of the Menderé. The old bed of that river is the Scamander, and its little tributary, the Dumbrek Su, is the Simois. In their fork lies Hissarlik or Troy. In sight of it are, on the one side, the peak of Samothrace (xiii. 11–14); on the other, the mass of the Kaz Dagh *Ida* (viii. 52). Hissarlik lies in the plain (xx. 216) less than 4 miles both from the Hellespontine and the Ægean coasts, easily reached day by day by foes from the shore, and possible to be left and regained in a single night by a Trojan visiting the camp of the Greeks (vii. 381–421). It is far less reasonable to demand a closer correspondence between the poem and geographical facts than to be astonished that the actual correspondence is so close.

In summarizing what has been found to exist on the mound of Hissarlik in the excavations undertaken there since 1870, it is not advisable to observe the order of the finding, since Schliemann's want of experience and method caused much confusion and error in the earlier revelations. No certainty as to the distinction of strata or their relative ages was possible till Wilhelm Dörpfeld obtained entire control in 1891, after the original explorer's death. There are in all nine strata of ancient settlement.

(1) On the virgin soil of the hillock, forming the core of the mound, scanty remains appear of a small village of the late Ægean Neolithic period, at the dawn of the Bronze Age. This includes what were originally supposed by Schliemann to be two successive primitive settlements. Thin walls of rough stones, bonded with mud, are preserved mainly in the west centre of the mound. No ground plan of a house is recoverable, and there is no sign of an outer fortress wall. In this stratum were found implements in obsidian and other stones, clay whorls, a little worked ivory, and much dark monochrome pottery, either of a rough grey surface or (in the finer examples) treated with resin, highly hand-polished, and showing simple geometric decoration, which was incised and often filled in with a white substance.

(2) Superposed on these remains, where they still exist, but comprehending a much larger area, lies a better-constructed and better-preserved settlement. This has been twice rebuilt, and it was enclosed by a massive fortress wall of rudely squared Cyclopean character, showing different restorations, and now destroyed except on the south side of the mound. Double gates at the south-east and south-west are well preserved. The most complete and most important structures within the citadel lie towards the north. These are two rectangular blocks lying north-west to south-east, side by side, of which the southern and larger shows a *megaron* and vestibule of the type familiar in "Mycenæan" palaces, while the smaller seems a pendant to the larger, like the "women's quarters" at Tiryns and Phylakopi (see Mycenæan Civilization). Other blocks, whose plans are difficult to bring into inter-relation in their present state of ruin, are scattered over the area, but mainly in the south-west. This is the fortress proclaimed by Schliemann in 1873 to be the Pergamos of Troy. But we now know that, while his identifications of Homeric topographical details in these ruins were fanciful, a much larger fortress succeeded to this long before the period treated of in the *Iliad*. The settlement in the second stratum belongs in fact to a primitive stage of that Ægean civilization which preceded the Mycenæan; and it is this latter that is recalled by the Homeric poems. The pottery of the second stratum at Hissarlik shows the first introduction of paint, and of the "slip" and somewhat fantastic forms parallel to those of the pre-Mycenæan style in the Cyclades. The beaked vases, known as *schnabelkannen*, are characteristic, and rude reproductions of human features are common in this ware, which seems all to be of native fabrication. Bronze had come into use for implements, weapons, and utensils; and gold and silver make up a hoarded treasure found in the calcined ruins of the fortification wall near one of the gates. But the forms are primitive and singular, and the workmanship is very rude, the pendants of the great diadems being cut out of very thin plate gold. Discs, bracelets, and pendants, showing advanced spiraliform ornament, found mainly in 1878, and then ascribed to this same stratum, belong undoubtedly to a higher one, the sixth or "Mycenæan." Rough fiddle-shaped idols, whorls, a little worked ivory, and some lead make up a find of whose early period comparison of objects found elsewhere leaves no sort of doubt. This treasure is now deposited in Berlin and in Constantinople, but the larger part in the former city.

(3, 4, 5) This primitive "Troy" suffered cataclysmal ruin (traces of conflagration are everywhere present), and Hissarlik ceased for a time to have any considerable population. Three small village settlements, not much more than farms, were successively erected on the site, and have left their traces superposed one on another, but they yielded no finds of importance.

(6) The mound, however, stood in too important a relation to the plain and the sea to remain desolate, and in due time it was covered again by a great fortress, while a city spread out below. The latter has never yet been explored, but is a principal object of Dr W. Dörpfeld's future plans. The remains of this stratum on the acropolis, however, have now been examined. A portion of

them was first distinguished clearly by Dörpfeld in 1882, but owing to the confusion caused by Schliemann's drastic methods of trenching, the pottery and metal objects, really belonging to this stratum, had come to be confused with those of lower strata; and some grey monochrome ware, obviously of Anatolian make, was alone referred to the higher stratum. To this ware Schliemann gave the name "Lydian," and the stratum was spoken of in his *Troja* (1884) as the "Lydian city."

In 1893, however, excavations were carried out on the south of the mound in the hitherto undisturbed ground outside the limits of the earlier fortress; and here appeared a second curtain wall of massive ashlar masonry showing architectural features which characterize the "Mycenæan" fortification walls at Mycenæ itself, and at Phylakopi in Melos. With this wall was associated not only the grey ware, but a mass of painted potsherds of unmistakably "Mycenæan" character; and further search in the same stratum to west and east showed that such sherds always lay on its floor level. The inevitable inference is that here we have a city, contemporary with the mass of the remains at Mycenæ, which imported "Mycenæan" ware to supplement its own ruder products. The area of its citadel is larger than the citadel of the second stratum; its buildings, of which a large *megaron* on the south-west and several houses on the east remain, are of much finer construction than those which lie lower. This was the most important city yet built on the mound of Hissarlik. It belonged to the "Mycenæan" Age, which precedes the composition of the Homeric poems, and is reflected by them. Therefore this is Homer's Troy.

Its remains, however, having been obliterated on the crown of Hissarlik, almost escaped recognition. When some centuries later a third important city, the Hellenistic Ilios, was built, all the accumulation on the top of the mound was cut away and a terrace made. In this process the then uppermost strata of ruins wholly vanished, their stones being taken to build the new city. The Mycenæan town, however, which had been piled stage upon stage to the summit, descended on the south side a little down the face of the mound; and the remains of its fortifications and houses at that point, lying below the level cut down to by the Hellenistic terrace-makers, were covered by the depositing of rubbish from the crown and again built over. Thus we find them now on the southern slope of the mound only, but have no difficulty in estimating their original extent. Many tombs and a large lower city of this era will doubtless be explored ere long.

(7) To "Mycenæan" Troy succeeded a small unfortified settlement, which maintained itself all through the Hellenic age till the Homeric enthusiasm of Alexander the Great called a city again into being on Hissarlik.

(8) The Hellenistic Ilios, however, has left comparatively little trace, having been almost completely destroyed in 85 B.C. by Fimbria. Portions of fortifications erected by Lysimachus are visible both on the acropolis (west face chiefly) and round the lower city in the plain. A small Doric temple belongs to the foundation of this city, and a larger one, probably dedicated to Athena, seems to be of the Pergamene Age. Of its metopes, representing Helios and a gigantomachia, important fragments have been recovered. Coins of this city are not rare, showing Athena on both faces, and some inscriptions have been recovered proving that Hellenistic Ilios was an important municipality.

(9) Lastly, about the Christian era, arose a Græco-Roman city, to which belong the theatre on the south-east slope of the hill and the ornate gateway in the same quarter, as well as a large building on the south-west and extensive remains to north-east.

(D. G. H.)

Troy, a city of New York, U.S.A., capital of Rensselaer county. It is on the Hudson river at the mouth of the Mohawk, and near Albany, in the eastern part of the state. It is regularly laid out, has a water-supply by the Holly system, is sewered, and is well paved with granite blocks, bricks, and asphalt. It has three railways — the Delaware and Hudson, the New York Central and Hudson River, and the Fitchburg (Boston and Maine), which, with the Erie canal and boats on the Hudson, give it a large traffic. In 1900 there were 662 manufacturing establishments, with a total capital of $23,531,622. They employed 21,564 hands, and their total output was valued at $28,209,259. The most important products were furnishing goods, with a value of $8,685,676; foundry and machine-shop products, $1,777,543; malt liquors, $1,438,869; and shirts, $4,774,520. Troy is the largest shirt-manufacturing place in the United States. Rensselaer Polytechnic Institute, situated here, in 1898 had 15 professors, and was attended by 138 students. In 1900 the assessed valuation of real and personal property was $49,147,550, the net debt was $1,506,056, and the rate of taxation was $19·71 per $1000. Population (1890), 60,956; (1900), 60,651, of whom 14,384 were foreign-born and 400 negroes. Of 17,038 males 21 years of age and over, 895 were illiterate (unable to write).

Troy, a city of Ohio, U.S.A., capital of Miami county, on the Miami river, the Miami and Erie canal, and at the intersection of the Cleveland, Cincinnati, Chicago, and St Louis, and the Cincinnati, Hamilton, and Dayton railways, in the western part of the state. Population (1890), 4494; (1900), 5881, of whom 234 were foreign-born and 391 negroes.

Troyes, chief town of the department of Aube, France, 104 miles east-south-east of Paris, on the railway from Paris to Mulhouse. Many of the old timbered houses have been destroyed, and of modern structures the principal is the Monument des Enfants d'Aube, erected in 1890 in commemoration of the war of 1870–71. The library, now containing 110,000 volumes, has been installed in a new building, and a school of hosiery has been added to the educational establishments of the town (1888). Population (1891), 47,551; (1901), 51,195.

Troyon, Constant (1810–1865), French painter, was born on the 28th of August 1810 at Sèvres, near Paris, where his father was connected with the famous manufactory of China. Troyon was an animal painter of the first rank, and was closely associated with the artists who painted around Barbizon. The technical qualities of his methods of painting are most masterly; his drawing is excellent, and his composition always interesting. It was only comparatively late in life that Troyon found his *métier*, but when he realized his power of painting animals he produced a fairly large number of good pictures in a few years. Troyon entered the *ateliers* very young as a decorator, and until he was twenty he laboured assiduously at the minute details of porcelain ornamentation; and this kind of work he mastered so thoroughly that it was many years before he overcame its limitations. By the time he reached twenty-one he was travelling the country as an artist, and painting landscapes so long as his finances lasted. Then when pressed for money he made friends with the first china manufacturer he met, and worked steadily at his old business of decorator until he had accumulated enough funds to permit him to start again on his wanderings.

Troyon was a favourite with Roqueplan, an artist of distinction eight years his senior, and he became one of his pupils after having received certain tuition from a painter, now quite unknown, named Riocreux. Roqueplan introduced Troyon to Rousseau, Jules Dupré, and the other Barbizon painters, and in his pictures between 1840 and 1847 he seemed to endeavour to follow in their footsteps. But as a landscapist Troyon would never have been recognized as a thorough master, although his work of the period is marked with much sincerity and met with a certain success. It may be pointed out, however, that in one or two pure landscapes of the end of his life he achieved qualities of the highest artistic kind; but this was after lengthy experience as a cattle painter, by which his talents had become thoroughly developed.

In 1846 Troyon went to the Netherlands, and at The Hague saw Paul Potter's famous "Young Bull." From the studies he made of this picture, of Cuyp's sunny landscapes, and Rembrandt's noble masterpieces he soon evolved a new method of painting, and it is only in works produced after

this time that Troyon's true individuality is revealed. When he became conscious of his power as an animal painter he developed with rapidity and success, until his works became recognized as masterpieces in Great Britain and America, as well as in all countries of the Continent. Success, however, came too late, for Troyon never quite believed in it himself, and even when he could command the market of several countries he still grumbled loudly at the way the world treated him. Yet he was decorated with the Legion of Honour, and five times received medals at the Paris Salon, while Napoleon III. was one of his patrons; and it is certain he was at least as financially successful as his Barbizon colleagues.

Troyon died, unmarried, at Paris on 21st February 1865, after a term of clouded intellect. All his famous pictures are of date between 1850 and 1864, his earlier work being of comparatively little value. His mother, who survived him, instituted the Troyon Prize for animal pictures at the École des Beaux Arts. Troyon's work is fairly well known to the public through a number of large engravings from his pictures.

In the Wallace Gallery in London are "Watering Cattle" and "Cattle in Stormy Weather"; in the Glasgow Corporation Gallery is a "Landscape with Cattle"; the Louvre contains his famous "Oxen at Work" and "Returning to the Farm" (see PLATE), while the Metropolitan Art Museum and other galleries in America contain fine examples of his pictures. His "Vallée de la Toucque, Normandy," is one of his greatest pictures; and at Christie's sale-room in 1902 the single figure of a cow in a landscape of but moderate quality fetched £7350. Émile van Marcke (1827–1891) was his best-known pupil.

Trübau. See BÖHMISCH-TRÜBAU.

Trujillo, a town of Spain, province of Caceres, on a hill to the east of Caceres. The country around is rugged, but produces wheat, wine, oils, and fruit, besides live-stock of all sorts. Much phosphorite is found in the district, and the extraction of it has been resumed. Valuable forests are close to the town. In the oldest part of Trujillo are the remains of a Roman castle and the Julia tower, also Roman, like much of the fortifications. The streets are broad, and there are some fine squares. The principal parish church, Santa Maria, is a fine Gothic structure of the 15th century. Besides its Roman records, Trujillo was a town of importance in the Middle Ages. Pizarro, the conqueror of Peru, was born here. Population (1887), 10,773; (1897), 12,254.

Truro, episcopal city, municipal borough, and market town, in the Truro parliamentary division of Cornwall, England, at the confluence of the Allen and the Kenwyn, 11 miles north of Falmouth by rail on the Great Western Railway. Truro cathedral (begun 1880, and designed by Mr Pearson) was opened in 1887. That part of it consisting of the old south aisle of the former parish church forms a small parochial church of itself, and by Act of Parliament of 1887 has all the legal rights of a parish church. A free library has been opened. There are tin-smelting works, several potteries, a boot factory, a biscuit factory, and works for jam-making and for the manufacture of shirts and clothing. Area, 1127 acres. Population (1891), 11,131; (1901), 11,562.

Truro, the chief town of Colchester county, Nova Scotia, on the Salmon river, near the head of Cobequid Bay and 61 miles from Halifax by rail. It contains 10 churches, county and school buildings, provincial normal school, a factory for condensing milk, besides other factories and mills. Victoria Park is noted for its natural beauty. Population (1891), 5102; (1901), 5993.

Trust Companies.—Trust companies, as defined in this article, are confined almost exclusively to the United States, and are the growth of the last half of the 19th century. They mainly differ from banks of deposit and discount in the following particulars:—they are incorporated only under state laws; usually they must invest their capital in first-class securities, and also deposit large amounts in United States or city bonds with the respective state superintendents of banks; they do not issue circulating notes; they do not, as a rule, discount commercial paper, although they frequently buy such paper, often when representing large amounts due from corporations which have other business relations with them; they pay interest on the deposits of customers, rarely more than 2 per cent., or perhaps a little more on moneys deposited for a stated period; they make loans on real estate, usually for large amounts, although on a conservative basis such as 50 per cent. of the appraised value; they act in fiduciary capacities, such as executors, trustees, receivers, committees, agents for corporations, fiscal agents for states, cities, or other municipalities, registrars or transfer agents for shares of capital stock, agents for the payment of coupons on the bonds issued by corporations, agents for the underwriting of new securities, depositaries of securities called for under plans of reorganization or held in escrow pending the transfer of ownership. Because of the more permanent character of their deposits, they are able to use such deposits for the general purposes enumerated above, many of which are foreign to the business of national and state banks. By reason of their special powers, the stable nature of their business, and their continued existence, trust companies have steadily grown in favour as executors or trustees of large estates. In Philadelphia, New York, and Boston this department had by 1900 assumed large proportions. In some parts of the United States, notably the Central West, the businesses of the trust company and the savings bank are combined by special charter, but as a rule, and especially in New York City, where the largest trust companies are situated, the trust company does not act as a savings bank. Some of the trust companies do not encourage the deposit of moneys subject to withdrawal on demand, preferring to restrict their deposit account to moneys held on an arrangement partaking of the nature of a trust, the latter sums being usually larger in amount, and not so liable to withdrawal as individual deposits. Because of the nature of the general business performed by trust companies, no portion of their deposits is required by law to be held as a cash reserve; as a result the deposit accounts of the trust companies with the national and state banks are among the largest which those banks carry, it being customary for the latter to pay interest upon such balances. As a rule, trust companies exist only in the larger cities, and the profits accumulated by some of the companies, particularly those concerned with syndicate operations, are often very large. In recent years it has become customary to organize trust companies with a large paid-up surplus. This is often made equal to the total of the capital stock issued, the subscription price of the stock then being made twice the amount of its par value. On 2nd January 1900 the combined capital and surplus of the forty-two trust

"Le Retour à la Ferme" By Troyon.

companies doing business in the city of New York was $126,081,123, while their deposits on that date amounted to $485,711,429. Of the 614 loan and trust companies in the United States which gave more or less complete information to the public authorities at the close of the year 1899, 612 reported a paid-up capital of $203,587,935; 506 had surplus and undivided profits of $176,925,270; 434 had in cash and due from banks the amount of $231,774,508. The deposits of 504 of such loan and trust companies amounted to $1,156,784,312, while the loans, discounts, and securities on hand reported by 497 of such companies amounted to $1,145,353,387.

(T. L. G.)

Trustees.—The chief modifications since 1887 of the English law of trust have been made by the Trustee Act, 1888, the Trustee Act, 1893, and the Judicial Trustees Act, 1896, and relate mainly to the position of trustees. It may be stated generally that the previous statute law concerning trustees was consolidated by the Trustee Act, 1893. In the article in the ninth edition of the *Encyclopædia Britannica* it was stated in regard to investments that legislation had conferred on trustees a right to invest in certain securities. The Trustee Act, 1893, has consolidated the law on this point, and now provides, as it were, a code or charter of investment authorizing trustees, unless expressly forbidden by the instrument (if any) creating the trust, to invest trust funds in various modes, of which the more important are as follows :—In any of the parliamentary stocks or public funds or Government securities of the United Kingdom; on real or heritable securities in Great Britain or Ireland; in stock of the Bank of England or the Bank of Ireland; in India 3½ per cent. stock and India 3 per cent. stock; in any securities, the interest of which is for the time being guaranteed by Parliament; in consolidated stock created by the London County Council; in the debenture or rent charge or guaranteed or preference stock of any railway company in Great Britain or Ireland incorporated by special Act of Parliament, and having during each of the ten years last past before the date of investment paid a dividend at the rate of not less than 3 per cent. on its ordinary stock; in the debenture stock of any railway company in India, the interest on which is paid or guaranteed by the secretary of state in council of India; in the "B" annuities of the Eastern Bengal, the East Indian, and the Sind, Punjab, and Delhi railways; and also in deferred annuities—comprised in the register of holders of annuity Class D, and annuities comprised in the register of annuitants Class C of the East Indian Railway Company; in the stock of any railway company in India upon which a fixed or minimum dividend in sterling is paid or guaranteed by the secretary of state in council of India, or upon the capital of which the interest is so guaranteed; in the debenture or guaranteed or preference stock of any company in Great Britain or Ireland established for the supply of water for profit, and incorporated by special Act of Parliament or by royal charter, and having during each of the ten years last past before the date of investment paid a dividend of not less than £5 per cent. per annum on its ordinary stock; in nominal or inscribed stock issued, or to be issued, by the corporation of any municipal borough having, according to the returns of the last census prior to the date of investment, a population exceeding 50,000, or by any county council under the authority of any Act of Parliament or Provisional Order; in any of the stocks, funds, or securities for the time being authorized for the investment of cash under the control or subject to the order of the High Court. Trustees may from time to time vary any such investments for others of an authorized nature. The statutory power to invest on real securities does not, of course, authorize the purchase of realty; but by § 5 of the Trustee Act, 1893, a power to invest in real securities (in the absence of express provision to the contrary) authorizes investment on mortgage of leasehold property held for an unexpired term of not less than 200 years and not subject to a greater rent than one shilling a year, or to any right of redemption or condition of re-entry except for non-payment of rent.

The Judicial Trustees Act, 1896, inaugurated a semi-official system of trusteeship which was new in England, but had been known in Scotland for upwards of 150 years. The general scope of the Act is indicated by § 1 (1), which runs as follows :—"Where application is made to the court by or on behalf of the person creating or intending to create a trust, or by or on behalf of a trustee or beneficiary, the court may, in its discretion, appoint a person (in this Act called a judicial trustee) to be a trustee of that trust, either jointly with any other person or as sole trustee, and if sufficient cause is shown, in place of all or any existing trustees." The Act and the rules made under it (the Judicial Trustees Rules, 1897) provide that judicial trustees shall be under the control and supervision of the court as officers thereof, and may be paid for their services out of the trust property. The trust accounts are to be audited annually, and a report thereon made to the court, which has power to order inquiries into transactions connected with the administration of the trust. A judicial trustee may be required to give security, and in any case has to keep the trust account with a bank approved by the court, and deposit title-deeds and other documents of title in such custody as the court directs. Communications between judicial trustees and the court with reference to their duties are permitted to be made with little or no formality, and strict proof of facts may be waived in proper cases. The Act may, in short, be described as an attempt to provide for an official check upon the administration of trusts, while avoiding the formality and expense incident to the procedure in an administration action.

The position of trustees in respect of what was frequently an undue personal responsibility for the administration of their trust has been much improved by § 8 of the Trustee Act, 1888 (not repealed by the Trustee Act, 1893), and § 3 of the Judicial Trustees Act, 1896. Sub-section (1) of the former enactment (with some omissions) runs as follows :—"In any action or other proceeding against a trustee or any person claiming through him, except where the claim is founded upon any fraud or fraudulent breach of trust to which the trustee was party or privy, or is to recover trust property, or the proceeds thereof still retained by the trustee, or previously received by the trustee and converted to his use, the following provisions shall apply—(*a*) All rights and privileges conferred by any statute of limitations shall be enjoyed in the like manner and to the like extent as if the trustee or person claiming through him had not been a trustee or person claiming through him. (*b*) If the action or other proceeding is brought to recover money or other property, and is one to which no existing statute of limitations applies, the trustee or person claiming through him shall be entitled to the benefit of, and be at liberty to plead the lapse of time as a bar to such action or other proceeding in the like manner and to the like extent as if the claim had been against him in an action of debt for money had and received." The statutory period of limitation which trustees are thus permitted to plead is the six years fixed as the period of limitation for actions of debt by the Limitation Act, 1623. It has been decided on the above section that in the case of a breach of trust consisting of an improper investment of the trust funds, time begins to run in favour

of the trustee from the date of the investment. Subsection (3) of the Judicial Trustees Act, 1896, provides that "If it appears to the court that a trustee, whether appointed under that Act or not, is or may be personally liable for any breach of trust, whether the transaction alleged to be a breach of trust occurred before or after the passing of that Act, but has acted honestly and reasonably, and ought fairly to be excused for the breach of trust and for omitting to obtain the directions of the court in the matter in which he committed such breach, then the court may relieve the trustee either wholly or partly from personal liability for the same." Owing to the generally reduced rate of interest obtainable for money invested on trust securities, the court has in several instances, and even as against defaulting trustees, charged them with interest at 3 per cent. per annum (instead of 4 per cent., which was formerly the recognized rate) upon sums found due from them to the trust estate.

Under the old law trustees could not safely advance on mortgage more than two-thirds of the actual value of agricultural land or one-half of the value of houses. This "two-thirds rule" is now made statutory by § 8 of the Trustee Act, 1893, which enacts that "A trustee lending money on the security of any property on which he can lawfully lend shall not be chargeable with breach of trust by reason only of the proportion borne by the amount of the loan to the value of the property at the time when the loan was made, provided that it appears to the court that in making the loan the trustee was acting upon a report as to the value of the property made by a person whom he reasonably believed to be an able practical surveyor or valuer instructed and employed independently of any owner of the property, whether such surveyor or valuer carried on business in the locality where the property is situate or elsewhere, and that the amount of the loan does not exceed two equal third parts of the value of the property as stated in the report, and that the loan was made under the advice of the surveyor or valuer expressed in the report." The same section protects trustees for not investigating the lessor's title when lending on the leasehold security, and for taking a shorter title than they might be otherwise entitled to on the purchase or mortgage of any property, if they act with prudence and caution. By § 9 (replacing § 5 of the Trustee Act, 1888), trustees who commit a breach of trust by lending more than the proper amount on any property are excused from making good any more than the excess of the actual loan over the sum which they might have properly lent in the first instance.

An inconvenience which formerly attached to dealings with trustees and trust property, in consequence partly of the rule "delegatus non potest delegare," and partly of the liability of persons dealing with trustees to see that money paid to them is properly applied, has been largely obviated by § 17 of the Trustee Act, 1893 (replacing § 2 of the Trustee Act, 1888), which in effect provides that a trustee may appoint a solicitor to be his agent to receive and give a discharge for any money or valuable consideration or property receivable by the trustee under the trust, by permitting the solicitor to have the custody of and to produce a deed having in the body thereof or endorsed thereon a receipt for the consideration money or other consideration, the deed being executed or the endorsed receipt being signed by the trustee; and a trustee is not chargeable with breach of trust by reason only of his having made or concurred in making any such appointment; and the producing of any such deed by the solicitor is a sufficient authority to the person liable to pay for his paying to the solicitor without the solicitor producing any separate or other direction or authority in that behalf from the trustee. The rule of equity by which a beneficiary who consented to a breach of trust was liable to indemnify the trustees to the extent of his interest has now taken definite statutory shape in § 45 of the Trustee Act, 1893 (replacing § 6 of the Trustee Act, 1888), which enacts that when a trustee commits a breach of trust at the instigation or request, or with the consent in writing of a beneficiary, the High Court may, if it thinks fit, and notwithstanding that the beneficiary is a married woman entitled for her separate use and restrained from anticipation, make such order as to the court seems just for impounding all or any part of the interest of the beneficiary in the trust estate by way of indemnity to the trustee.

The Intestates' Estates Act, 1884, has altered the previous law as to escheat, by which a trustee became entitled for his own benefit to real estate held upon trust for a *cestui que* trust who died intestate and without heirs, so that now equitable estates escheat in the same manner as legal estates. (E. M. Bs.)

United States.

A trustee under American law is generally entitled to compensation for his services. Charitable trusts are becoming more frequent as the wealth of the United States increases, and are regarded with more favour by the courts. The *cy pres* doctrine has been either expressly or virtually applied to uphold them in several of the states, and in some there has been legislation in the same direction. Spendthrift trusts, *i.e.*, those under which the enjoyment of income bequeathed by will in such a way as to prevent creditors of the beneficiary from reaching it before it gets into his hands, are generally supported (*Nichols* v. *Eaton*, 91 United States Reports, 713).

A "voting trust" is a concerted transfer of their shares in a corporation by a majority of the shareholders to trustees to hold and vote on them for a specified period for the purpose of securing the adoption or continuance of a certain line of corporate action. Any shareholder may recede from such an arrangement and reclaim his stock. (S. E. B.)

Trusts.—The word "trusts," as used in this article, includes all those aggregations of capital engaged in productive industry that, by virtue of their industrial strength, have or are supposed to have some monopolistic power. Legal monopolies, as such, and natural monopolies are excluded, although it is frequently true that the trusts are aided by and sometimes control natural monopolies. Trusts are here considered to be identical with the so-called "capitalistic monopolies."

While it is probably true that trusts are a product of evolution, it is desirable to analyse and explain that conception in some detail if we are to understand their industrial significance. Competition, especially among industries managed on a great scale, often makes modern business unprofitable. Commercial men have been thus compelled in some way to modify former methods of doing business. So long as most industries were run on a small scale, the differences in the ability and the facilities of the various competitors were so great that only those at the lower end of the scale of excellence were forced out of the business—this to the general advantage of industrial society. The great mass of producers remained vigorously competing with one another, some making larger, others smaller profits, but all except a few at the lower margin making at least a living. Under modern business conditions competitors are often, relatively speaking, few in number, of substantially equal ability, and controlling substantially equal facilities for managing the business economically. Consequently, in such circumstances, modern competition differs greatly from that form which was familiar to the earlier economists. Among competitors of such great resources, the struggle may last long after the business has become unprofitable to all before any will fail. Among competitors so nearly equal in strength, the entire industry

may be very seriously injured by competition before enough are forced out to affect materially the severity of the competition.

The dictum of Stephenson, that "where combination is possible, competition is impossible," has a much wider application now than in the early days of railways. The modern facilities for the transportation of goods, for the rapid transmission of intelligence by fast mail, and especially for the instantaneous exchange of information by the telegraph and telephone, have made it possible to manage easily a large business, however widely separated its different plants or establishments may be. Half a century ago or thereabouts, on account of the lack of these facilities, management of such institutions would often have been impossible. Many of the advantages of combinations are entirely dependent upon these modern facilities, and on that account these facilities may be said to be an occasion, if not a cause, of the trusts.

Two kinds of trust industries.

If the product of an industry is of such a nature that its quality is substantially uniform and can be readily tested by purchasers, especially if the goods are such that they are ordinarily sold in large quantities, the competition between rival establishments must almost of necessity be a competition in price. Sugar refining, oil refining, the distilling of spirits, the manufacture of salt, are such industries. The standard quality is readily tested, and the manufacturer who can offer the standard product at the lowest price effects a sale. Industries manufacturing comparatively inexpensive articles for the retail trade, put them up in packages which become well known to customers; and those industries whose goods are sold under brands or trade-marks, or in some other form so that they are familiar to buyers, afford an example of competition of an entirely different kind. When the reputation of a certain brand of goods of this nature becomes established, consumers make no further efforts to test its quality, and the retail price often becomes a customary price. If a manufacturer of such goods finds his trade injured by a rival, his most effective means of competition will often be, not a lowering of the price, but an increase of the outlay on advertising. Soap, baking-powder, photographic cameras for general use, and of late years certain brands of coffee, patent medicines, and other goods of similar nature, are examples of this class. Those industries in which the competition becomes a matter of cutting of prices can by combination remove rivals from the field, and then put prices up to a remunerative rate. Competitors in industries of the second class by combination can save many of the costs of selling, and thus without any increase in the price of the product may save enough of the cost to make the business profitable.

Some of the advantages of combination over competition which have led to the organization of trusts may be enumerated:—

Savings from combination.

(1) The cost of selling may be greatly lessened. As has been intimated, competition in the case of industries of the second class named above leads to very expensive advertising in order to effect sales. An examination of the pages of any of the American magazines, with a thought as to the amount charged for the use of these advertising pages (from one hundred to as high as even four hundred dollars, or from £20 to £80, per page for a single insertion in some of the magazines with the largest circulation) will convince one of the cost of such competitive advertising. The expense involved in making attractive show windows in stores or shops, and in calling the attention of the public to popular wares by posters scattered about the country and by legends painted on rocks, on buildings along the lines of railways, &c., are other common examples.

(2) The salaries of commercial travellers, together with their hotel and travelling expenses, are of a similar nature. This competitive advertising in many cases does not increase to any noteworthy extent the consumption of the products in question, but merely attracts customers from one manufacturer to another. Combination among establishments that do this costly advertising saves a large part of the expense without lessening materially the quantity of goods sold.

(3) If different manufacturing establishments, scattered throughout the country, are brought under one management, it will be possible for orders for goods to be received at one central office, and then to be distributed to the federated establishments, so that goods can be despatched to customers in each case from the nearest establishment. In this way freight expenses may be very greatly lessened, cross freights over the same territory being substantially eliminated. A single establishment supplying all of its customers would often be compelled to deliver much longer distances at greatly increased expense.

(4) The entire profit of an establishment frequently depends upon the skill of the manager. When many different establishments are organized into one, it is possible to select the most skilful manager of all and to put him in charge of the combination, thus securing in many cases, if the trust includes practically all of the establishments in the entire industry, the ablest manager in the country for them all. It is of course true that as an establishment increases in size, or as a combination increases the number of its branches, especially if they are widely scattered, it becomes impossible for the manager to give his personal supervision to the details of management of each institution. An executive officer of the highest skill, however, will so select his subordinates, so direct their work, and so infuse into them his own spirit, that, under careful inspection, comparatively little will be lost from his inability to be present personally in each separate establishment. In the larger combinations frequent reports, often daily, are made from each concern, giving in detail the quantity of the output, the quality of the goods, the exact cost of the different processes of manufacture; so that it is possible to compare continually each of them with all of the others; to detect the special weakness of each, and in this way to remedy any slight defects in any one establishment, and to bring all nearly up to the highest level of productive capacity.

(5) Each business manager is likely to have some special excellence in his methods of management. One will be particularly skilful in the technique of manufacturing; another in the organization of the business; a third in selling goods, and so on. By combining many establishments into one, it is possible so to distribute this managerial skill that each superintendent will be given the department for which he is peculiarly fitted, and the whole establishment will thus get the benefit, not merely of the best executive ability at the head, but also of the best managing skill at the head of each separate department. In many cases it is probable that as much is saved in this way as in any other.

(6) Besides this distribution of skill of the managers, it is sometimes equally beneficial to distribute the various products of the combination among the different plants. For example, in the manufacture of hoop and bar iron the products are turned out in great varieties of size, probably from seventy-five to a hundred. Wholesale dealers in sending their orders to the mills are likely to call for from ten to fifty different kinds. If these orders go to an establishment which has but one large mill, it may

be necessary, in order to execute the order, to change the rolls in the mill several times, causing thus a waste of power, of time, and of energy. If several establishments are combined, each can be equipped for certain sizes. When, in these circumstances, a large order is received, to each establishment will be sent that part of the order which it is especially equipped to fulfil, and thus, without any changes of rolls or stoppage of machinery, the separate sizes can be made. The same principle holds of course in nearly all lines of work, in some to a greater degree than in others; but in the manufacture of hoop and bar iron a saving from this source amounting to from a dollar to a dollar and a half, or from 4s. to 6s., per ton is sometimes made.

(7) The advantage of unifying in one establishment the manufacture of products somewhat allied in nature appears also in selling goods. If customers can buy all of the various kinds of related goods in one establishment, much of their time and energy will be saved. Some of the larger combinations, therefore, in order to make this saving for their customers and thus to be sure of retaining their orders, add to their plant facilities for making products which a smaller establishment could hardly manufacture. For example, the Distilling Company of America, which controls probably 90 per cent. of the entire product of corn spirits, found it to its advantage to add to its plant several rye distilleries, and to purchase a number of the leading brands of whiskies for consumption as beverages, in order that they might supply the needs along different lines of practically all dealers in spirits and whiskies, in this way saving for themselves many customers who otherwise might have been lost.

(8) The mere size of an establishment and its ability to supply at any time on short notice any order, however large, gives it also an advantage in retaining custom. A concern that controls only from 5 to 10 per cent. of the entire output of a country in any special line of goods might at times find it impossible to supply goods promptly. Large customers who might thus be embarrassed are more ready to deal regularly with an establishment controlling 75 to 90 per cent. of the output, if they can in this way be sure of having their orders attended to promptly. It is stated that the American Sugar Refining Company on this account is able to secure, with considerable regularity, one-sixteenth of a cent a pound more on its refined sugars than the independent refiners, the latter being frequently compelled to cut their prices to that extent in order to make sales.

(9) Owing to the fact that the introduction of goods into new markets, especially into foreign markets, is a matter of time, expenditure of energy, and of money, the large establishment with great capital has in this particular also a decided advantage. The Standard Oil Company, and American Tobacco Company, and other similar establishments, have thus been able to open up new markets in Europe, in Japan, China, and other portions of the Far East more readily by far than individual producers along those lines could have done. This stimulus to the foreign trade acts also beneficially to the domestic trade, inasmuch as the exportation of part of the product tends to keep prices somewhat higher at home, and as the added demand for the raw material influences its price, thus creates a demand for labour along many lines.

(10) The combination also frequently saves for its stockholders considerable sums from its wiser dealing with credits, and this in a way also that is beneficial to the entire business community. When competition is very severe among different establishments, the managers, in order to increase their sales, will not infrequently grant credit somewhat unwisely. The combination controlling a large part of the market is not so tempted, and moreover has the power to bring needed pressure to bear upon delinquent debtors more readily, so that losses from bad debts are much less frequent.

Besides the special savings which have been mentioned above that serve as reasons for the formation of combinations, certain special favours at times lead to their formation.

Special favours to combinations.

(1) The protective tariff is most frequently cited as such a favour. By the protection which a protective duty gives against foreign competition, it doubtless often furnishes the occasion for the formation of trusts. If a large amount of capital is tempted into the industry through the profits promised by the tariff, and therefore competition among the various establishments becomes fierce, it is much easier for them to form a combination with the certainty of good profits, provided the domestic competition can be overcome, if they are certain that foreign competition also is to be excluded. On the other hand, it would hardly be right to speak of the tariff as in this case the direct cause. In other industries not protected by the tariff the same fierce competition leads to the formation of combinations. The tariff is simply an encouraging condition. The removal of the tariff would not destroy the combination unless it destroyed the industry at the same time; but, on the other hand, the removal of a protective tariff might very easily prevent the abuses of exorbitant prices which might be exacted by a combination protected by the tariff.

(2) It is doubtless true that combinations have a good many times been encouraged by special discriminating rates of freight granted by the railways or other transportation agencies. There is, of course, a certain economic advantage to the railways in having goods despatched in large quantities by consigners who are able to supply their own cars, loading and unloading facilities, &c. Railways on that account often prefer to deal with large firms, and, other things being equal, are willing to give them some special rates. These concerns also are likely to have rather better credit than the smaller ones, so that dealing with them ensures prompt pay and cheaper collection of accounts. The competition among the different railways also for the freights which an important customer can furnish leads to cutting of the rates in their favour. These special rates, however, whether justified from the business point of view or not, are beyond any question from the social point of view often a very grave injury. A manufacturer who receives these special favours can build up a business substantially monopolistic in its extent, whereas his rival of equal or even of greater ability, and equally skilful as a manufacturer, would be ruined if he did not receive like rates. The injustice of such discriminations and their evil effects on the community have been recognized by legislatures and courts in America, and they are practically universally forbidden. It nevertheless remains beyond question true that they are very frequently granted even at the present time.

In recent years in the United States there can be little question that the formation of the great combinations has been much encouraged by the opportunities, which promoters were able to seize, of making for themselves large profits. The movement towards combination was so fully recognized and the advantages in many cases so palpable, that a well-informed and skilful promoter was often able to persuade a large proportion of the manufacturers in some special industry to combine. In preparing the plan for such combination, the promoter has in many cases seen to it that he himself first bought the properties which he could very shortly turn over to the combination at high rates of profit; or else he has

Promotion.

been able to persuade the new corporation to issue large amounts of stock, of which considerable proportions were given to him in return for his services. It has been true in many cases that these securities have been speculative in nature, but nevertheless the promoter has often reaped in this way large rewards. The possibility of this profit has doubtless stimulated his activity in urging the combinations.

Associated with the promoter in the organization of these combinations have usually been bankers or other financiers who stood ready, for an amount of stock or other promised profit sufficiently large to compensate them for their risk, to furnish to the combinations cash sufficient to start the business and to provide other needed capital. Usually the form of underwriting employed has been this: A promoter engaged in the formation of a combination and needing a certain fixed sum in cash, would make an arrangement with a bank to sell to it at a price agreed upon such portions of a named amount of stock as were not disposed of to other customers before a certain fixed date. For example, the bank might agree to furnish one million dollars in cash (£200,000) in return for say four millions of stock (£800,000), or to purchase itself at a fixed price all the remainder of the $4,000,000 stock unsold at the date agreed upon, the bank itself to become the sales agent. In those circumstances the bank would naturally use its best endeavours to sell the four millions of stock to other customers at the price agreed upon, say twenty-five dollars, or £5, per share. So far as it failed of disposing of the entire amount, it would take the remainder itself. For taking these risks, naturally the bank has almost invariably asked a very high commission, and not infrequently it has been asserted that the managers of the banks have been given a special bonus for themselves privately, in addition to the rates of profits granted the bank.

The underwriter.

These large amounts of stock that are paid to the promoter and the financier for the purpose of bringing about the organization of a large trust, lead, of course, to what is called over-capitalization. What the proper basis of capitalization for a manufacturing industry should be, is a matter that cannot perhaps easily be determined by a definite principle which shall be applicable in every case. The laws that have been most strict on the subject attempt to limit the capitalization to the "actual cash value" of the business, by that being understood at times simply the cost of the plant itself with the running cash capital needed. On the other hand, most business men think that it is a wiser plan, and on the whole equally just, to capitalize a business on the basis of its earning capacity, regardless of what the plant may have cost. When, as has been frequently the case of late years, in addition to this cash value of the plant and the cash itself which may have been paid in, large sums of stock are issued also for properties which may be in themselves highly overvalued, and for the services of the promoter, the financier, and others, we can see that the capitalization must be far above what may ordinarily be considered a paying basis. On the other hand, if the element of monopoly enters into the business to any noteworthy extent, the prices of the product may be kept so high that fair dividends may be paid even on this high capitalization. That the tendency towards increasing the capital has been very strong there can be no question. It is probable that in the near future the penalty that must be paid for this somewhat reckless financiering will have to be endured. As soon as a slight depression in business comes, so that it is perfectly evident not merely that dividends cannot be paid on the common stock, but that in all probability both the deferred stock and the bonds, if any have been issued, will also have to go without interest, it will be necessary to reorganize many of these combinations and to start them anew on a much lower capitalization. According to a report of the United States Census Office, the actual value of the manufacturing capital employed by combinations which it investigated, June 1900, including 2147 works, was $1,458,522,573. This huge sum equalled only 47·3 per cent. of the securities issued, though it exceeded the amount of bonds and preferred stock. The sum does not include the value of certain forest and mining lands held by some companies.

The basis of capitalization.

When the person organizing the combination is himself an active business man, and has the intention of himself directing the affairs of the combination, another element besides that of personal profit very frequently enters into the problem. Most strong men like to take responsibility and to be dominant in affairs. When, owing to the advantages of combination that have been enumerated above, the prospect of a virtual monopoly seems certain, provided due skill in management is exercised, it is natural that the manager should wish to bring about the combination in order that he may himself have the satisfaction of being in substantially absolute control of the entire industry in a country, or possibly even in the world. The ambition thus to dominate in a great industry is akin to that of a statesman, and there can be little question that this pride of power and the desire to control the destinies of others has been a more or less conscious element in the formation of many of the most successful and most skilfully managed combinations.

The industrial manager.

(1) The form of combination which has ordinarily been first adopted has been some kind of agreement with reference to maintaining prices, or to paying wages, or to dividing the territory for the distribution of the product, or similar questions. Experience has shown that, generally speaking, such agreements are not likely to be kept in good faith for a long period.

The forms of combination.

(2) In order to make the combination more permanent in its nature, the form of the trust, technically so called, was adopted. Under this form of combination, the stockholders of the various constituent companies of the trust place their stock in the hands of a small board of trustees, giving to these trustees an irrevocable power of attorney to vote the stock as they see fit, or in accordance with specific instructions given at the beginning. The title to the stock itself remains in the original holder, with the right to sell or pledge or dispose of it as he sees fit, but without the power of recalling his right to vote. In return for this stock thus deposited with the trustees, the trustees have ordinarily issued trust certificates, which are in themselves negotiable, and take the place of the stock. Inasmuch as the holding of the voting power of the majority of the stock of each of the different constituent companies gave to the trustees absolute power of election of directors, and consequently the power of guiding harmoniously the affairs of all of the plant entering into the combination regardless of the will of the stockholders, the United States courts held that the corporations entering into such an agreement had gone beyond their powers, and that such a trust was illegal. Owing chiefly to these hostile decisions of the courts, this form of trust was abandoned, and new forms, which still, however, leave the power of unified direction in the hands of a few men, were adopted.

(3) After the trusts were declared illegal, it was usual, when a combination was formed, to organize a new corporation which bought all of the properties of the

constituent members of the trust. These constituent companies then dissolved, and the one great corporation owning all of the properties remained.

(4) The form that of late seems to be much in favour approaches in its general nature more closely to that of the original trust. Under this form, a corporation is organized for the special purpose of buying and owning all, or a controlling share, of the stocks of each one of the constituent companies. The separate companies are then managed technically independently, the dividends of the separate corporations are all paid to the parent corporation as the stockholder owning all of the stocks, and these dividends are the source of profits of the new corporation. The officers in this parent corporation, of course, vote the stocks of the separate companies, and thus absolutely control.

The trust and wages.

From the savings which it is possible for the combinations to make, it would seem possible for them to pay higher rates of wages to those remaining in their employment than it was possible for the constituent companies to do. In certain instances, especially when the combination has first been made, wages have been increased. On the whole, however, it is probable that as yet the wage-earners have succeeded in getting an increase of wages in circumstances substantially similar to those under which their wages would be increased by single corporations. An increase of wages comes only through pressure on their part. Under a prosperous condition of industry it is possible, without materially lowering profits, to increase the wages.

Certain classes of employés, especially superintendents and commercial travellers, are less needed by the combinations, and consequently the total sum of wages paid to these classes by the combination is less than that formerly paid by the constituent companies. On the other hand, the number of employés of these classes being less than before, the average wage has, in certain cases at least, been increased. Owing to the fact that competitive selling is in certain cases largely done away with, it has in some, perhaps in many, cases been possible for fewer travelling salesmen, of less skill and with lower wages, to do the work than before the combination, so that not merely has the total expense been lessened, but also the average salary paid to those retained in the business.

In case of disputes arising between the combination and the operatives, the position of the combination is stronger than that of an individual corporation. It is possible to close one or two works where troubles have arisen, and to transfer orders to the other works without any material injury to the business, provided the closing of the one or two establishments is not for too long a period. Such instances have occurred. On the other hand, labour organizations are also rapidly increasing in strength, and their leaders are of the opinion that within a comparatively short time they will be so thoroughly organized in all of the chief industries that a strike can be instituted and supported not merely in one or two establishments, but throughout the entire industry. Whenever this condition of affairs shall have been reached, the employés will be substantially on an equality with their employers in such cases of conflict, so that the advantage now resting with the combination will be largely removed. In certain industries this condition seems already to have been reached.

Prices.

From the sources of savings that were enumerated before, it is evident that it would be possible for a combination either to increase the prices paid for raw materials, or to lower the prices of its finished products. Experience, however, seems to show beyond question that whenever the combinations are powerful enough to secure a monopolistic control, it has usually been the policy to increase the prices above those which obtained during the period of competition preceding the formation of the combination. Inasmuch, however, as an attempt to increase prices to any great extent, so as to secure very high profits, would certainly result in tempting new capital into the field, it has been the general experience that prices have either been increased only comparatively little after the combination was formed, or else that competition entering the field has comparatively soon forced a lowering of prices to substantially the former competitive rates. It should be noted, however, that inasmuch as combinations have very frequently been formed only after a period of competition so fierce that practically all the competitors were running at a loss, it is hardly just to speak of a combination placing its prices above "competitive rates" unless one defines what is meant exactly by that expression. Whenever they have put their prices above the competitive rates existing just before the combination, it may mean that they have put their prices back to rates that will allow medium profits instead of losses, and not above rates that would be normal in the case of small competitors.

Legislative remedies.

It will have been noted from what has been said that the excellences of the combination consist largely in the savings that have already been enumerated. The evils are: (1) The losses to investors through the acts of the promoters and financiers at the time of the organization of the combinations, and through the speculation in the stocks which is at times carried on by the directors of the combinations themselves. (2) The losses to the wage-earners from the power that sometimes exists of forcing wages rather lower than it would be possible for a single corporation or manufacturer to do, and also from the discharge of certain classes of employés whose services are no longer needed, such as commercial travellers. It should be remarked of the latter case, however, that the injury is a personal one to those men that are discharged, but that it results in a saving to the community, and therefore presumably to the wage-earning class as a whole in the long run. (3) A further injury at times to the consumer arises, as has been suggested, from the increase in price. Other evils come through the power that is sometimes exercised by combinations in the corruption of legislatures; in the control over industries of such a nature that it tends to destroy the spirit of individual activity and independence on the part of many persons who would otherwise enter business independently; and evils also come through the increased force of any improper or dishonourable business practices, since this added force for evil is given to any combination by virtue of its greater influence in the community. It is not intended to convey the impression that managers of combinations are less moral than other business men, but merely that whenever they are dishonourable in their practices the influence reaches more widely.

The chief remedies for these evils enumerated would seem to be more rigid laws with reference to the methods of incorporation and to the responsibility of directors to stockholders and to the public. This can perhaps best be brought about through greater publicity in both of these directions, probably under the inspection of Government officials. The other line of remedies would seem to be the removal of special favours granted to these combinations either by the Government or by railways or other bodies so situated that they can distribute favours to the larger combinations.

The movement towards consolidation of industries in the United States began to be noticeable soon after the Civil War (1861–65), but it had not reached noteworthy

proportions, excepting in connexion with the railways, until within the last twenty years of the 19th century.

The movement towards consolidation.

During the later years many consolidations were made, the largest number during the years 1898–1900. From what has been said earlier, it is evident that certain classes of industries, especially those that require the investment of fixed capital to large amounts, are especially adapted for combination. Very little tendency towards consolidation is found in the farming industry, and, relatively speaking, little in industries that require the investment of but small capital. It is perhaps, however, not too much to say that in nearly all lines of industry which from their nature are adapted for consolidation combinations more or less firm have been made during the last few years. It is probable that as time passes we shall have many of these combinations reorganized, and that in many lines of industry there will be further consolidation of present combinations.

Experience has shown that when combinations are made in industries that from their nature do not seem well suited for consolidation, failure follows. In many individual instances corporation lawyers, who have had much practice in forming combinations, advise their clients in lines of business especially fitted for competition not to enter a combination, but to remain independent, assuring them that an individual is able to compete in such lines of industry with any combination, however large. Such advice of course would not be given were the industry one which was well adapted for consolidation.

According to the United States census report of 1900, it seems a fair inference that not over one quarter of the value of the manufactured products of the United States is as yet produced by the combinations, powerful as they are in many lines.

Great Britain.—The tendency toward consolidation has been for several years very noticeable in Great Britain, although until within the last few years the form has been rather that of a pool or ring than that of a trust or of a single large corporation. In the coal and milling industries there have been agreements; and, particularly in London and other distributing centres, these selling combinations have been able at times to control the market. This has also been true with reference to certain kinds of provisions, such as the bacon imported from Denmark.

European experience.

Of late years there has been a marked tendency towards the formation of large corporations that buy up a very large proportion of competing manufacturing plant, and in this way secure at least a temporary monopoly of the market. The Salt Union was formed along these lines, but this has not proved successful, owing probably to the fact that new sources of supply were discovered. The dyeing industries in Bradford and in Yorkshire have been consolidated, so that in certain respects they have an absolute monopoly of the business, and in most directions of over 90 per cent. of it. The calico printers, the fine cotton spinners, the thread manufacturers, the bleachers, and others connected with the cotton manufacturing industries in Great Britain, have nearly all been brought together into large corporations which control from 90 per cent. upwards of the entire business. Similar combinations in cement, wall-paper, soap, and other trades have been formed. Most of these large corporations have been in existence for such a short time that one cannot yet judge accurately regarding their permanent success. Many of them seem to have been overcapitalized, and their dividends have not always met shareholders' anticipations. There has been no active popular movement against consolidation in England, and the Government has passed no laws opposed to it. Parliament, however, has passed stringent amendments to the Companies Acts, changes enforcing publicity regarding the organization of all limited liability companies and their methods of management. The amended law is expected to prevent most of the abuses of the combinations.

Germany.—Germany seems to be peculiarly the home of combinations so far as Europe is concerned. In 1897 Liefmann, writing regarding combinations in Germany, was able to mention combinations which were international in their scope in forty-one different branches of industry. Of combinations that were confined to Germany alone he mentioned 345, although many of them were in the same line of industry: for example, he found 80 combinations in different branches of the iron industry, 82 in the chemical industries, 38 in the textiles, and so on. Of that number he thought that definite information could be secured, but he was of the opinion that very many more of less importance existed, and had excluded from his reckoning all of those that were purely local, as for example those among the breweries in the different cities, as well as those among firms engaged merely in trade. The form of combination in Germany is ordinarily that merely of contracts among independent establishments regulating the amount of output for each, and in certain cases also the prices. As in Austria and in France, a central selling bureau for all the members of the combination is frequently found. The most successful combinations have been those among the coal-miners in western Germany, and the four or five in the leading branches of iron manufacture, also in western Germany. Lately two others of somewhat similar rank have been organized, one in the sugar industry, which includes both refiners and producers, and one among the manufacturers of spirits. The former, following that among the Austrian sugar manufacturers, is somewhat peculiar in that the refiners guarantee to the producers of raw sugar a fixed price for their output so far as the sugar is intended for the home market, the refiners expecting to recoup themselves from the consumers through the monopolistic power which they possess. The law does not seem to be hostile to these combinations. Contracts that are immoral in their nature are, of course, non-enforceable. But the courts have, on the whole, not taken an attitude inimical to the larger combinations, and the Government seems at times to have been inclined to favour them. In one or two cases where the Government is itself a producer, as of soda, it is a member of a combination. Comparatively lately, one of the Prussian ministers in a speech in the Landtag expressed himself favourably regarding the coal and iron combinations. The facts seem to show that the coal combination, at any rate, has used its power of fixing prices in a conservative way, and that during 1901 it has apparently held prices somewhat lower than they probably would have been had free competition existed in that industry. So long as the combinations are managed thus conservatively, and so long as the Government is able to secure a careful supervision over them, it is not to be expected that there will be much hostility in Germany on the part of the Government.

France.—The number of combinations in France is probably much less than in Great Britain or Germany. In the Penal Code there has been a provision for many years against monopoly brought about by unfair means, and in one or two rather prominent instances there seem to have been convictions under this article. Consequently, the agreements that have been made, so far as they are intended to control prices, are usually kept secret. There have been, however, notably in the case of the iron industries, agreements made among the leading

manufacturers, under which the proportion of output assigned to each was fixed. A single selling bureau has also in such cases been established, which receives all orders, and fixes the prices for all of the different establishments concerned. So far this form of organization, although in certain localities it seems to have secured monopolistic power, has not been successfully attacked in the courts. For several years it has been supposed that a similar agreement existed among the sugar refiners. They themselves, however, acknowledge only an agreement regarding the amount of the output which shall be assigned to each, and deny any agreement as to prices. Of course an agreement regarding output would be likely to have a material effect upon prices. Somewhat similar combinations exist among the petroleum refiners, the porcelain makers, and some few others. The Government has taken no active steps in the matter, but popular opinion seems to be awakening somewhat.

Austria.—In Austria the development of combinations has been very marked. The most successful combination, on the whole, as well as one of the earliest, has been that of the iron industry. The sugar industry, however, including both refiners and producers of the raw sugar, and the petroleum industry, are also combinations of great power. The form of these combinations is ordinarily that of an agreement regarding both output and prices. In some instances a central selling bureau fixes the prices, in others the market is divided, while in others still other forms of agreements of many kinds which serve to secure a monopoly are found. The movement has spread very rapidly indeed, until, in the opinion of many writers in Austria, practically all branches of industry, in which agreements for the lessening of competition will prove advantageous, are now largely controlled by combinations. The courts of Austria have, on the whole, within the last few years shown themselves hostile to the movement. Contracts for the division of the market, for the assignment of fixed proportions of the entire output to different establishments, the fixing of prices, &c., are declared void, and will not be enforced by the courts. This adverse action, however, does not seem to have affected very materially the tendency towards combination, although it has perhaps tended somewhat to encourage the formation of large corporations which should purchase all of the separate plant in any one industry. This tendency, again, is checked by the fact that the corporation law requires publicity in business, and that the taxes are heavier on corporations than on private firms, both as regards the legal rate and the certainty of collection. A Government commission has recommended recognition of the combinations by law and their careful supervision and regulation by governmental authority. (J. W. J.)

Tryon, Sir George (1832–1893), British admiral, a younger son of Thomas Tryon, of Bulwick Park, Northamptonshire, was born on 4th January 1832. He entered the navy in 1848, on board Lord Dundonald's flagship on the North American station; was afterwards in the *Vengeance* with Lord Edward Russell in the Black Sea; was landed for service with the naval brigade; and was made a lieutenant in November, but dated back to 21st October 1854. From 1855 to 1858 he was in the *Royal Albert*, flagship of Sir Edmund Lyons; and from 1858 to 1860 in the royal yacht, which gave him his promotion to commander on 25th October 1860. From 1861 to 1864 he was commander of the *Warrior*, the first British sea-going ironclad; from 1864 to 1866 he commanded the *Surprise* gun-vessel in the Mediterranean; and was promoted to be captain on 11th April 1866. In 1867 he was sent out as director of transports and store ships for the Abyssinian expedition, a post which involved a great deal of hard work in a sweltering and unhealthy climate. He discharged his duties exceedingly well, but his health broke down, and he returned to England a helpless invalid. From 1871 to 1873 he was private secretary to Mr Goschen, then First Lord of the Admiralty; and from 1874 to 1877 commanded the *Raleigh* in India with the Prince of Wales, and afterwards in the Mediterranean. In the years 1878–81 he had command of the *Monarch*, one of the Mediterranean fleet under Sir Geoffrey Hornby and Sir Beauchamp Seymour, afterwards Lord Alcester. He was afterwards for two years secretary of the Admiralty; and for three years more, on his promotion in April 1884 to the rank of rear-admiral, commander-in-chief on the Australian station. On his return, in June 1887, he was made K.C.B.; afterwards he was for three years superintendent of reserves, in which capacity it fell to him to command one of the opposing fleets during the summer manœuvres, when he showed marked ability and originality of ideas. In 1889 he was promoted to be vice-admiral; and in August 1891 was appointed to command the Mediterranean fleet, which under him—following the example of his old chief, Sir Geoffrey Hornby—became very distinctly an evolutionary and, in that sense, experimental squadron. Some of his methods were afterwards said to be dangerous; but those which were most severely criticized do not appear to have had anything to do with the lamentable accident which ended Tryon's career. On the 22nd June 1893, the fleet being then off Tripoli on the coast of Syria, in two columns, Tryon made the signal to invert the course, the ships turning inwards in succession. By a fatal error, the psychological cause of which has never been explained, he ignored the patent fact that the two columns were so near each other that the manœuvre, as ordered, must entail the most serious risk, if not certainty, of collision. And in fact the two leading ships did come into collision, with the result that the *Victoria*, Tryon's flagship, was cut open and sank in a few minutes. Tryon and a lamentably large proportion of the men were drowned. A full *Life* of Tryon, by Rear-Admiral C. C. Penrose FitzGerald, has been published. He had married in 1869, and left issue. (J. K. L.)

Tsaidam. See TIBET.

Tsanpo. See BRAHMAPUTRA.

Tschaïkovsky, Peter Iliitsch (1840–1893), Russian composer, born at Votkinsk, in the province of Vyatka, on the 7th May 1840, was the son of a mining engineer, who shortly after the boy's birth removed to St Petersburg to assume the duties of director of the Technological Institute there. While studying in the School of Jurisprudence, and later, while holding office in the Ministry of Justice, Tschaïkovsky picked up a smattering of musical knowledge sufficient to qualify him as an adept amateur performer. Thus he became in demand in society. But the seriousness of his musical aspirations led him to join the classes held in connexion with the famous Musical Society, after which he entered the Conservatorium under Zaremba, and was induced by Anton Rubinstein, its principal, to take up music as a profession. He therefore resigned his post in the Ministry of Justice. On quitting the Conservatorium he was awarded a silver medal for his thesis, a cantata on Schiller's "Ode to Joy." In 1866 Tschaïkovsky became practically the first chief of the recently founded Moscow Conservatorium, since Seroff, whom he succeeded, never took up his appointment. Although in Moscow Tschaïkovsky missed the life and bustle of St Petersburg, he met many artistic people whose services were useful. Thus Ostroffsky wrote for him his first opera libretto,

The Vojevoda. After the Russian Musical Society had rejected a concert overture written at Rubinstein's suggestion, Tschaikovsky in 1866 was much occupied on his *Winter Day Dreams*, a symphonic poem, which proved a failure in St Petersburg but a success at Moscow. In 1867 he made an unsuccessful début as conductor. Failure still dogged his steps, for in January 1869 his *Vojevoda* disappeared off the boards after ten performances, and subsequently Tschaikovsky destroyed the score. The *Romeo and Juliet* overture has been much altered since its production by the Russian Musical Society in 1870, in which year the composer once more attempted unsuccessfully an operatic production, St Petersburg rejecting his *Undine*. In 1871 Tschaïkovsky was busy on his cantata for the opening of the Exhibition in celebration of the bicentenary of Peter the Great, his opera *The Oprischnik*, and a textbook of harmony, which latter was adopted by the Moscow Conservatorium authorities. At Moscow in 1873 his incidental music to the *Snow Queen* failed, but some success came next year with the beautiful quartet in F. During these years Tschaïkovsky was musical critic for two journals. On the death of Seroff he competed for the best setting of Polousky's *Wakula the Smith*, and won the first two prizes. Yet on its production at St Petersburg in November 1876 this work gained only a *succès d'estime*. Since then it has been much revised, and is now known as *The Little Shoes*. Meanwhile the Second Symphony and the *Tempest* fantasia had been heard, and the pianoforte concerto in B flat minor completed. This was first played by von Bülow in Boston, U.S.A., some time later, and was entirely revised and republished in 1889. At last something like success came to Tschaïkovsky with the production of *The Oprischnik*, in which he had incorporated much of the best of *The Vojevoda*. The Third—or Polish—Symphony, four sets of songs, the E flat quartet (dedicated to the memory of Lamb), the ballet *The Swan Lake*, and the *Francesca da Rimini* fantasia all belong to the period of the late 'seventies—the last being a *rechauffé* of operatic remains. Opera still possessed Tschaïkovsky, who in 1877 first conceived the germs of *Eugen Onegin*. With the production of this opera at the Moscow Conservatorium in March 1879 real success first came to him. The story, by Pushkin, was a familiar one, and the music not so extravagant in its demands as in the earlier operas. Over part of this period of Tschaïkovsky's life a mystery still hangs. M. Kashkin, his best friend, believes that even in 1877 the composer was engaged to be married. But no word on the subject ever passed between them, and the first intimation Kashkin received was his meeting with Tschaïkovsky and his wife in the autumn of that year. From this time Tschaïkovsky was a changed man. He became taciturn to moroseness, and finally he quitted Moscow and his friends for St Petersburg. There he fell ill, and an attempt to commit suicide by standing chin-high in the river in a frost (whereby he hoped to catch his death from exposure) was only frustrated by his brother's tender care. With his brother Tschaikovsky went to Clarens to recuperate. In 1878 he accepted (but later resigned) the post of director of the Russian musical department at the Paris Exhibition, completed his Fourth Symphony and the Italian Capriccio, and worked hard at his "1812" overture, more songs, the second pianoforte concerto, and his interesting "Liturgy of St Chrysostom." This latter nearly came to an untimely end through the officialdom which necessitated the imprimatur on all Greek Church music of the Court Chapel-Master, Bortniansky, who had been in his grave nearly half a century! The year of rest following Tschaikovsky's domestic *débâcle* gave him a taste for freedom. Consequently he returned only for a short time to Moscow. Thence he went to Paris. In 1879 he wrote his *Maid of Orleans* (produced in 1880) and his first suite for orchestra. In 1881 Nicholas Rubinstein died—to whose memory Tschaïkovsky dedicated one of his most beautiful and characteristic works, the trio in A minor. The following five years saw him fully occupied with travels, and working at *Manfred* and *Hamlet*, the operas *Mazeppa* and *Charodaïka*, the Mozartian suite, and the fine Fifth Symphony. During a great part of the time he lived in retirement at Klin, where his generosity to the poor made him beloved. His operas *The Queen of Spades* and the one-act *Iolanthe* were feeble by comparison with his earlier works, but the *Sleeping Beauty* and *Casse-Noisette* ballets are quite charming. In 1893 Tschaïkovsky sketched his Sixth Symphony, now known as the Pathetic, a work that has done more for his fame in foreign lands than all the rest of his works. This symphony was at first thought to have aroused undue sympathy from an entirely fictitious autobiographical interest, and from its having been first conducted by the composer within ten days of his sudden death. Tschaïkovsky died from cholera at St Petersburg, 6th November 1893, barely six months after Cambridge University had conferred on him in person the honorary degree of Doctor in Music.

PETER ILIITSCH TSCHAÏKOVSKY.
(From a photograph by Reutlinger, Paris.)

Tschaïkovsky's work is so unequal that it would be possible, by carefully chosen examples of his music, to prove him at once one of the immortals of music and a merely mediocre composer. In dramatic affairs he lacked point precisely as Anton Rubinstein lacked point. But in the matter of invention of broad, sweeping melody Tschaïkovsky was far ahead of his compatriot, and as a composer of music saturated with what are popularly

understood to be national Russian characteristics was on a plane far above the other. Among his songs and smaller pianoforte works, as in his symphonies and quartets, are passages of exquisite beauty; while, on the other hand, *bizarrerie*, and even downright uncouthness, are not always to seek. But the best of Tschaikovsky's work commands whole-hearted admiration. It is more distinctly Russian and more beautiful than that of most of his compatriots; it is not disguised German music, as is so much by Rubinstein and Glazounow, and it is not incoherently ferocious, like so much by Balakireff. Probably time will place Tschaikovsky somewhere after Glinka and before his own contemporaries. (R. H. L.)

Tschudi.—The historical reputation of Giles Tschudi (1505–1572) has suffered very much owing to recent researches. His inventions as to the early history of the Swiss Confederation have been described under TELL. His statements and documents relating to Roman times and the early history of Glarus and his own family had long roused suspicion. Detailed examination of late years has proved beyond the shadow of a doubt that he not merely claimed to have copied Roman inscriptions that never existed, and amended others in a most arbitrary fashion, but that he deliberately forged a number of documents with a view to pushing back the origin of his family to the 10th century, thus also entirely misrepresenting the early history of Glarus, which is that of a democratic community, and not (as he pretended) that of a preserve of several aristocratic families. Tschudi's historical credit is thus hopelessly ruined, and no document printed or historical statement made by him can henceforward be accepted without careful verification and examination. These discoveries have a painful interest and importance, since down to the 19th century all Swiss historical writers had largely based their works on his investigations and manuscripts.

For a summary of these discoveries see Professor G. v. WYSS in the *Jahrbuch* of the Historical Society of Glarus, vol. xxx. (1895), in No. 1, 1894, of the *Anzeiger f. Schweizerische Geschichte*, and in his *Geschichte d. Historiographie in d. Schweiz* (1895), pp. 201–2. The original articles by VÖGELIN (Roman inscriptions) appeared in vols. xi., xiv., and xv. (1886–1890) of the *Jahrbuch f. Schweizer Geschichte*, and that by SCHULTE (Glarus) in vol. xviii. (1893) of the same periodical. For a defence see a feeble pamphlet, *Schulte u. Tschudi* (Coire, 1898), by P. C. v. PLANTA. (W. A. B. C.)

Tsêng Kuo-fan (1811–1872), Chinese statesman and general, was born in 1811 in the province of Hunan, where he took in succession the three degrees of Chinese scholarship. In 1843 he was appointed chief literary examiner in the province of Szechuen, and six years later was made junior vice-president of the Board of Rites. When holding the office of military examiner (1851) he was compelled by the death of his mother to retire to his native district for the regulation mourning. At this time the Taiping rebels were overrunning Hunan in their conquering career, and had possessed themselves of the cities and strongholds on both shores of the Yangtse-kiang. By a special decree Tsêng was ordered to assist the governor of the province in raising a volunteer force, and on his own initiative he built a fleet of war junks, with which he attacked the rebels. In his first engagement he was defeated, but, happily for him, his lieutenants were more successful. They recovered the capital, Chang-sha, and destroyed the rebel fleet. Following up these victories of his subordinates, Tsêng recaptured Wuchang and Hanyang, near Hankow, and was rewarded for his success by being appointed vice-president of the Board of War. In 1853 other triumphs led to his being made a Baturu (a Manchu order for rewarding military prowess), and to his being decorated with a yellow riding-jacket. Meanwhile, in his absence, the rebels retook Wuchang and burnt the protecting fleet. The tide quickly turned, however, and Tsêng succeeded in clearing the country round the Poyang lake, and subsequently in ridding the province of Kiangsu of the enemy. His father died in 1857, and after a brief mourning he was ordered to take supreme command in Chekiang, and to co-operate with the governor of Fuhkien in the defence of that province. Subsequently the rebels were driven westwards, and Tsêng would have started in pursuit had he not been called on to clear the province of Anhwe of rebel bands. In 1860 he was appointed viceroy of the two Kiang provinces and imperial war commissioner. At this time, and for some time previously, he had been fortunate in having the active support of Tso Tsung-t'ang, who at a later period recovered Kashgar for the emperor, and of Li Hung-Chang. Like all true leaders of men, he knew how to reward good service, and when occasion offered he appointed the former to the governorship of Chekiang and the latter to that of Kiangsu. In 1862 he was appointed assistant grand secretary of state. At this time the imperial forces, assisted by the "Ever-victorious Army," had checked the progress of the rebellion, and Tsêng was able to carry out a scheme which he had long formulated of besieging Nanking, the rebel headquarters. While Gordon, with the help of Li Hung-Chang, was clearing the cities on the lower waters of the Yangtse-kiang, Tsêng drew closer his besieging lines around the doomed city. In July 1864 the city fell into his hands, and he was rewarded with the rank and title of marquis and the right to wear the double-eyed peacock's feather. After the suppression of the Taipings a rebellion, closely related to the former movement, broke out in Shantung, and Tsêng was sent to quell it. Success did not, however, always attend him on this campaign, and by imperial order he was relieved of his command by Li Hung-Chang, who in the same way succeeded him in the viceroyalty of Chihli, where, after the massacre of Tientsin (1870), Tsêng failed to carry out the wishes of his imperial master. After this rebuff he retired to his viceroyalty at Nanking, where he died in 1872. Tsêng was a voluminous writer. His papers addressed to the throne and his literary disquisitions are held in high esteem by the scholars of China, who treasure as a memorial of a great and uncorrupt statesman the edition of his collected works in 156 books, which was edited by Li Hung-Chang in 1876. (R. K. D.)

Tsetse Fly.—The tsetse fly (*Glossina morsitans*, Westwood) belongs to the dipterous family Muscidæ. It is sometimes locally called "Tsaltsaya," although it is generally known to the natives as the tsetse or tzetze fly. This pest is met with throughout Central, South, and East Africa, on the Congo, and up the Niger on the west coast. It is the active agent in spreading one of the most virulent equine diseases of South Africa, the so-called tsetse disease or *nagana*. This disease, which is caused by minute protozoa of the genus *Trypanosoma* in the blood, affects the horse chiefly, but is also found in the ox, ass, goat, dog, and such wild animals as the koodoo deer. The germs of this disease are spread by the tsetse fly, which is a blood-sucker. On obtaining the blood of a horse or other animal suffering from this complaint the fly also obtains some of these protozoal parasites, which even after two or three days' severance from their host retain their vitality. The germs which the tsetse fly has obtained are ejected into the next horse or ass which the insect attacks. At present it is not known if the fly acts in any way as an intermediate host, but it is generally assumed that it acts merely as a carrier of the hæmatozoa from beast to beast. In size the tsetse fly is about half

an inch long, that is, considerably larger than the common house fly (*Musca domestica*). Its thorax is deep chestnut-brown, with four dark longitudinal lines, and with small bristles, which when denuded show small black specks; the abdomen is bristly and dull yellowish-brown in colour, with black patches on the visible segments which are interrupted in the middle; the wings are of a smoky hue. The legs are buff-coloured with some yellowish markings. The proboscis is long, about twice the length of the head, and is in the form of a sharp piercing organ. When gorged with blood the female's abdomen swells to a great size and becomes reddish-brown beneath. Its favourite habitat seems to be the borders of marshes, river sides, places where animals go to water, and in and around beds of reeds. It is very local, sometimes being confined to one side of a river in thousands, whilst on the opposite bank not one can be found. The so-called "fly-zones" make transport by horse almost impossible where the tsetse disease occurs. When on the wing *Glossina morsitans* makes a loud buzzing noise. When at rest the wings fold over one another. The female has been shown by Bruce to produce her young viviparously. The larva is yellow and nearly as large as the abdomen of the parent; it is furnished with a black hood at one end and two hooks at the other, and consists of ten segments. After living a short free existence, it crawls into some hole or crevice, and in a few hours it has turned into a jet black puparium. The pupal stage lasts six weeks. The parent requires an enormous amount of blood for the nourishment of the young, hence she is always sucking blood from the various warm-blooded animals and man. The fly is found in districts in which tsetse disease does not occur, and when this is the case the bite alone, though annoying, produces no further results than irritation; when piercing the skin the proboscis causes a sharp prick. According to Bruce, the reason why *Glossina morsitans* only carries the virus is that, being viviparous, the mother has to take constant nourishment for her developing larvæ. The bite has no effect upon man even when the fly has just left a diseased animal, except by causing irritation. When attacking a horse the fly usually settles on the legs, but also sticks on to the belly, inside the thighs, and under the tail. Their favourite feeding-time is sunset, but they also bite by moonlight.

(F. V. T.)

Tsu-shima, signifying "the island of the port," an island belonging to Japan, situated about midway between Korea and the island of Iki, so that the two islands were used as places of call in former times by vessels plying between Japan and Korea. It lies a little to the east of 129° E. and a little to the north of 34° N. It has a circumference of 454 miles, an area of 262 miles, and a population of 38,636. It is almost completely divided at the waist by a deep sound (Asaji-ura), and the southern section has two mountains, Yatachi-yama and Shira-dake, 2130 feet and 1680 feet high respectively, while the northern section has Ibeshi-yama and Mi-take, whose heights are 1128 feet and 1598 feet. The chief town is Izu-ga-hara. The Mongol armada visited the island in the 13th century and committed great depredations. From Tsu-shima to Fusan, the principal Japanese settlement in Korea, the distance is 65 miles, but the nearest point of the Korean coast is only 48 miles distant.

Tuam, an episcopal city in the county of Galway, Ireland, on the Waterford, Limerick, and Western Railway, 129 miles west of Dublin. A place of great antiquity, it has always had intimate ecclesiastical connexions. The Protestant archbishopric of Tuam was lowered to a bishopric in 1834, and the see joined to that of Killaloe. It is, however, a Roman Catholic archbishopric. The Protestant cathedral is also the parish church, and was to a great extent rebuilt in the third quarter of the 19th century from plans by Sir Thomas Deane, at a cost of £16,000. Only the chancel of the old church remains, but its red sandstone arch is architecturally famous as a remarkably fine example of Norman work; it dates from the middle of the 12th century. The modern Roman Catholic cathedral is perpendicular in style and cruciform in plan. The interior is elaborately decorated. The Cross of Tuam, re-erected in modern times, bears inscriptions in memory of Turlogh O'Conor, king of Ireland, and O'Hoisin, successively (1128) abbot of St Jarlath's Abbey, founded in the 6th century, and archbishop (1152) of Tuam. St Jarlath's College is a seminary for the education of priests. Population (1891), 3012; (1901), 2890.

Tuamotu, an archipelago of coral formation in the South Pacific, between 14° and 24° S. and 135° and 150° W., officially part of the French dependency of Tahiti. The largest islands are Fakarava and Ravida; the former is the administrative headquarters of the French resident. With three or four exceptions they are flat, and the vegetation which grows upon the arid limestone is scanty. The group is, however, planted with cocoa-nut, breadfruit, bananas, water-melons, yams, &c., which form the chief subsistence of the natives. The fine fisheries in the rocky and surf waters are a source of revenue, the pearls being sold in Tahiti. The best harbour of the group is that of Fakarava, which, together with Mengarewa, is open to trade. The islands were first discovered by the Spaniard Pedro Fernandez Quiros in 1606. The area of the entire group is about 330 square miles, and the population is about 7000, all of whom are natives, with the exception of a few French officials and other Europeans. The group passed under the protection of France in 1844, and was absorbed into the Republic in 1881.

Tuat, a Berber word signifying "oasis," sometimes applied generally to all the oases of the Algerian Sahara between 0° and 2½° E., 26° and 29° N., sometimes restricted to a particular group which borders the east side of the Wad Mzaud between 26½° and 27½° N. According to the first-mentioned usage, it includes the oases of Gurara and Tidikelt with the important centre of Insalah. The district is comparatively fertile, being formed of recent alluvium extending along the base of the Tademait plateau (Cretaceous), and produces dates and some cereals and vegetables. It is peopled with a diversity of races, Arab, Berber, and negro being all represented, but the population is much less dense than formerly. The separate "ksur" or hamlets, of which the district is said to contain over 300, are in Tuat proper placed very closely together. The district is of importance as commanding the routes southwards to Timbuktu from both Morocco and Algeria, and it is thus a great centre of trade. Although formerly claimed by Morocco, the sovereignty of that kingdom has long been merely nominal, and the district was early in 1900 occupied by French troops as a step towards consolidating French influence over the routes to the south. Schemes have been set on foot for the extension of the Algerian railways to Tuat, the route most favoured being that *viâ* Figig and Igli (occupied later in 1900), following the course of the Wad Susfana and Wad Saura. A step in this direction has already been taken by the continuation of the Western Algerian Railway beyond Ain Sefra to Jenien-bu-Rezg (opened early in 1900). It has since been carried still farther.

See works by DEPORTER, Algiers, 1890–91.—FLAMAND, in *La Géographie*, May 1900; *Annales de Géographie*, 1900, pp. 233–242.

Tuberculosis. — The word "tuberculosis," as now used, signifies invasion of the body by the tubercle bacillus, and is applied generally to all morbid conditions set up by the presence of the active parasite. The name is derived from the "tubercles" or "little lumps" which are formed in tissues invaded by the bacillus; these were observed and described long before their real nature or causation was known. (For an account of the organism, which was discovered by Koch in 1882, see PATHOLOGY: *Parasitic Diseases*). The bacillus attacks every organ and tissue of the body, but some much more frequently than others. The commonest seats of tubercular disease are the lungs, lymphatic glands, bones, serous membranes, mucous membranes, intestines, and liver. Before the discovery of the bacillus its effects in different parts of the body received separate names and were classified as distinct diseases. For instance, tuberculosis of the lung was called "consumption" or "phthisis," of the bones and lymphatic glands "struma" or "scrofula," of the skin "lupus," of the intestine "tabes mesenterica." Some of these names are still retained for convenience, but the diseases indicated by them are known to be really forms of tuberculosis. On the other hand, there are "tubercles" which are not caused by the tubercle bacillus, but by some other source of irritation, including various parasitic organisms, some of which closely resemble the tubercle bacillus. To these forms of disease, which are not as yet well understood, the term pseudo-tuberculosis has been given. Lastly, the word "tubercular" is still sometimes applied to mere lumpy eruptions of the skin, which have no connexion with tuberculosis or pseudo-tuberculosis.

Pathology.—The effects of tuberculosis on the structures attacked vary greatly, but the characteristic feature of the disease is a breaking-down and destruction of tissue. Hence the word "phthisis," which means "wasting away" or "decay," and was used by Hippocrates, accurately describes the morbid process in tuberculosis generally, as well as the constitutional effect on the patient in consumption. According to the most recent views, the presence and multiplication of the bacilli excite by irritation the growth of epithelioid cells from the normal fixed cells of the tissue affected, and so form the tubercle, which at first consists of a collection of these morbidly-grown cells. In a typical tubercle there is usually a very large or "giant" cell in the centre, surrounded by smaller epithelioid cells, and outside these again a zone of leucocytes. The bacilli are scattered among the cells. In the earliest stages the tubercle is microscopic, but as several of them are formed close together they become visible to the naked eye and constitute the condition known as miliary tubercle, from their supposed resemblance to millet seeds. In the next stage the cells forming the tubercle undergo the degenerative change known as "caseation," which merely means that they assume in the mass an appearance something like cheese. In point of fact, they die. This degeneration is believed to be directly caused by a toxin produced by the bacilli. The further progress of the disease varies greatly, probably in accordance with the resisting power of the individual. In proportion as resistance is small and progress rapid the cheesy tubercles tend to soften and break down, forming abscesses that burst when superficial and leave ulcers, which in turn coalesce, causing extensive destruction of tissue. In proportion as progress is slow the breaking down and destructive process is replaced by one in which the formation of fibrous tissue is the chief feature. It may be regarded as Nature's method of defence and repair. In tuberculosis of the lungs, for instance, we have at one end of the scale acute phthisis or "galloping consumption," in which a large part or even the whole of a lung is a mass of caseous tubercle, or is honeycombed with large ragged cavities formed by the rapid destruction of lung tissue. At the other end we have patches or knots of fibrous tissue wholly replacing the original tubercles or enclosing what remains of them. Such old encapsuled tubercles may undergo calcareous degeneration. Between these extremes come conditions which partake of the nature of both in all degrees, and exhibit a mixture of the destructive and the healing processes in the shape of cavities surrounded by fibrous tissue. Such intermediate conditions are far more common than either extreme; they occur in ordinary chronic phthisis. The term "fibroid phthisis" is applied to cases in which the process is very chronic but extensive, so that considerable cavities are formed with much fibrous tissue, the contraction of which draws in and flattens the chest-wall. Tuberculosis commonly attacks one organ or part more than another, but it may take the form of an acute general fever, resembling typhoid in its clinical features. "Acute miliary tuberculosis" is a term generally used to indicate disseminated infection of some particular organ—usually the lungs or one of the serous membranes—in which the disease is so severe and rapid that the tubercles have not time to get beyond the miliary stage before death occurs. Tuberculosis is exceedingly apt to spread from its original seat and to invade other organs. The confusing multiplicity of terms used in connexion with this disease is due to its innumerable variations, and to attempts to classify diseases according to their symptoms or anatomical appearances. Now that the cause is known, and it has become clear that different forms of disease are caused by variations in extent, acuteness, and seat of attack, the whole subject has become greatly simplified, and many old terms might be dropped with advantage.

Tuberculosis in the Lower Animals.—Most creatures, including worms and fishes, are experimentally susceptible to tuberculosis, and some contract it spontaneously. It may be called a disease of civilization. Domesticated animals are more susceptible than wild ones, and the latter are more liable in captivity than in the natural state. Captive monkeys, for instance, commonly die of it, and of birds the most susceptible are farmyard fowls. Of the domesticated animals, horses and sheep are least, and cattle most, affected; pigs, dogs, and cats occupy an intermediate position. The percentage of tuberculous animals recorded at the slaughter-houses of Berlin in 1892–93 was as follows: Cows and oxen, 15·1; swine, 1·55; calves, 0·11; sheep, 0·004. Similar records at Copenhagen in 1890–93 give the following result: Cows and oxen, 17·7; swine, 15·3; calves, 0·2; sheep, 0·0003. The order of the animals is the same, and it is confirmed by other slaughter-house statistics; but the discrepancies between the figures indicate considerable variation in frequency, and only allow general conclusions to be drawn. A striking fact is the comparatively small amount of tubercle in calves. It shows, as Nocard has pointed out, that heredity cannot play an important part in the transmission of bovine tuberculosis. The infrequency of the disease in sheep is attributed to the open-air life they lead, and no doubt that is an important factor. The more animals and persons are herded together and breathe the same air in a confined and covered space, the more prevalent is tuberculosis among them. But there are evidently degrees of natural resistance also. Horses are more confined than cattle in the United Kingdom, yet they are far less affected; and on the other hand, cattle running free in the purest air may take the infection from others. Professor McEachran of Montreal states that he has

seen tuberculosis prevalent in ranche cattle, few of which were ever under a roof, ranging on the foothills of the Rocky Mountains in Montana. In cows and monkeys the lungs are chiefly affected; in horses and pigs the intestine and abdominal organs. The relation between human and animal tuberculosis has not yet been determined. The bacillus in man very closely resembles that found in other mammalia, and they were considered identical or interchangeable until Koch threw doubt upon this view at the British Congress on Tuberculosis in 1901. The bacillus in birds shows cultural differences, and is regarded as a distinct variety. Further reference will be made to this question, which has an important bearing on the spread and prevention of the disease.

Distribution and Mortality.—The distribution of tuberculosis is world-wide, and seems to be unaffected by geographical situation. The experiments of Mr Swithinbank, who exposed the bacilli to the temperature of liquid air (about 186° C. below zero) for forty-two days, prove that their vitality is not destroyed by the most intense cold. It is not surprising, therefore, to find that the disease prevails in Greenland and Siberia. Bright sunlight, on the contrary, is said to render the bacilli inert in a few hours (Koch, Ransome). Nevertheless tuberculosis flourishes in the tropics, India, and Australia. The natural conditions which are least favourable to it are those which combine sunshine, abundant air-currents, dry soil, and a certain altitude. In the midlands and highlands of Natal, for instance, Europeans and natives and cattle all enjoy nearly complete immunity (Allen). But in such localities, sparsely inhabited as a rule, both men and animals generally live an open-air life. Wherever they are aggregated together in dwellings tuberculosis is found among them. This appears to be a more important condition than climate, soil, or geographical situation. The comparative immunity of uncivilized races is explained by their open-air life; when brought to live under civilized conditions and in contact with white people they succumb far more readily than the latter. The coloured population of the United States, the Maoris, and South Sea Islanders illustrate this fact. Tuberculosis is most rife in large centres of population in which the people live under the worst air conditions. In addition to its universal distribution, it is constantly active, unlike the more acute parasitic diseases, and has no periods of remission or quiescence; consequently it is more destructive to life and health than any of them, more even than all of them put together. The annual mortality of the human race from this single cause is estimated at 5,000,000, or one-seventh of the whole (Hirsch). In some countries (Russia) it is believed to be nearly one-fourth of the whole. The annual death-roll of tuberculosis is about 170,000 in Germany, 150,000 in France, 150,000 in the United States, and 60,000 in England, where it has been steadily diminishing since 1838. The exact figures for England and Wales during the ten years 1881–90 are 589,390 deaths out of 5,244,771, that is, one-ninth of the total number. Consumption accounts for more than four-fifths of this mortality, namely, 473,968, the remaining fifth — 115,422 deaths — being ascribed to other forms of tuberculosis. It is probable that in countries where less progress has been made in combating consumption, its preponderance over other tubercular diseases is still greater; but full data are lacking. Attention has naturally been centred on consumption, on account of its excessive destructiveness, and a good deal of information has been collected with regard to its mortality in different countries and cities. The following table gives approximately the annual rates among European nations :—

Rates of Mortality from Consumption per 100,000 Living.

Russia (principal towns, 1890–92)	399
Austria (1895–96)	362
Hungary (1893–95)	318
France (principal towns, 1894–97)	302
Sweden (principal towns, 1894–97)	231
Germany (1894–97)	224
Switzerland (1894–97)	203
Ireland (1894–97)	203
Denmark (principal towns, 1894–97)	191
Holland (1892–95)	188
Italy (1895–97)	187
Belgium (1890)	177
Norway (1891–95)	173
Scotland (1893–96)	173
England and Wales (1894–97)	135

The excessive prevalence in Russia is explained by (1) low standard of living; (2) overcrowding in unventilated and overheated rooms in winter; (3) the use of furs, which harbour germs and are handed down from father to son. The two last factors operate also in other countries in central and northern Europe, but in a less degree.

Turning to the great cities, we find much higher rates prevailing. The following are towns of half a million inhabitants and upwards :—

Moscow (1889–92)	457	Berlin (1894–97)	237
St Petersburg (1889–92)	441	Glasgow (1894)	226
Vienna (1894–97)	427	Hamburg (1894–97)	211
Budapest (1894–97)	414	Manchester (1894)	196
Paris (1894–97)	387	Amsterdam (1894–97)	187
Rio de Janeiro (1894–97)	380	London (1894–97)	177
New York (1894–97)	252	Naples (1894–97)	176
Warsaw (1894–97)	245	Buenos Aires (1894–97)	165

The favourable position occupied by Naples is ascribed to the fact that for a century the Italians, forestalling science, have regarded consumption as infectious, and have practised the isolation of patients suffering from advanced phthisis.

The following table of mortality rates from consumption in American cities in 1895–99 is taken from statistics prepared by the Prudential Insurance Company of America :—

Denver	357	Dayton	186
San Francisco	288	Hartford	176
Albany, N.Y.	266	Atlanta	163
Newark	259	Fall River	161
New York	246	Chicago	154
Jersey City	241	Lynn, Mass.	141
Sacramento	240	Buffalo	129
Boston	237	Milwaukee	129
Providence	213	Spokane	126
Cincinnati	211	Reading, Pa.	124
Philadelphia	210	Minneapolis	123
Syracuse	199	Pittsburg	116
Camden	193	Nashville	102
Indianapolis	193	Salt Lake City	64
St Louis	187		

These figures compare favourably with those for provincial towns in Germany and France, as may be seen from the following rates for the year 1894 (*Münchener Medizinische Wochenschrift*) :—

Würzburg	524	Lyons	336
Havre	500	Augsburg	335
Rouen	450	Rheims	326
Nüremberg	393	Munich	308
Breslau	349	Nantes	301
Nancy	337	Roubaix	297

According to the registered mortality, tuberculosis has been decreasing in some countries for a number of years. This is the case with regard both to consumption and tuberculosis generally.

Death-rates from Tubercular Diseases per 100,000.

Year.	New York.	London.	Paris.	Berlin.	Vienna.
1884	445	312	519	362	720
1894	316	243	510	251	506

The records for England and Wales, which go back farther than any others, show a progressive diminution since 1838; but for strict comparison they are too imperfect in the early years of registration. Beginning with 1851–60, we find the death-rate from all tubercular diseases, which was 348 in that decade, had fallen gradually to 212 in 1891–95. Further details are given below. From the United States we have the following statistics (Hoffmann):—

Death-rates from Consumption in Five Eastern States and Ten other Cities, with a Total Population of 14,301,595 in 1899.

1871	333	1886	281
1885	289	1900	212
	Mean 307		Mean 232

In six large cities during the same period the death-rate among the white population fell gradually from 418 to 227, while among the coloured it fluctuated irregularly, but was always far higher, ranging from a maximum of 648 in 1885 to a minimum of 474 in 1899. In Saxony the death-rate from tubercular diseases is said to have fallen since 1892 from 250 to 210, and in Baden from 300 to 260.

Age and Sex.—The most complete information under this heading is derived from the English records. "In both sexes," says Dr Tatham, "the real liability to phthisis begins somewhere between the fifteenth and the twentieth year. Among males it attains its maximum at age 45–55, when it reaches 3173 per million living. Among females it attains its maximum (2096) at age 35–45. In both sexes the rate rapidly declines after the attainment of its maximum. Practically the incidence of phthisis is upon the ages from 15 to 75 years, very old people and young children being comparatively exempt. According to recent experience, females seem to be rather *less liable* than males to death by phthisis at ages under 5 years, *more liable* at the age of 5–20, and again *less liable* at subsequent ages." These observations, it must be noted, refer only to consumption. The comparative immunity of the very young does not extend to all forms of tubercular disease. On the contrary, tuberculosis of the bowels, or tabes mesenterica, and tubercular meningitis are pre-eminently diseases of childhood. The following tables show in detail the relative incidence of consumption at different ages, and the steady diminution of the disease in England and Wales since 1850:—

ENGLAND AND WALES.

Tubercular Phthisis.—Mortality in several Periods, 1851–99. Annual Rate per Million Living.

MALES.

Period.	Ages.											
	All Ages.	Under 5 Years.	5—	10—	15—	20—	25—	35—	45—	55—	65—	75—

1896–99	1141	334	201	410	1165	1547	1862	2096	1597	1242	787	366

Commenting on these tables, Dr Tatham remarks that, "with a few trifling exceptions, every age group in both sexes has experienced *a decrease* in the mortality ascribed to phthisis. In every case the mortality in 1895–99 was lower than it had been in 1851–60; but the rate of decrease has varied widely, and has been much greater among females than among males. The reduction indicated by the table may not be wholly real, and may be due in part to the vaguer statement of causes of death in the earlier period; as, for instance, by the habitual use of the terms 'consumption' and 'decline' to describe any lingering disease of the lungs attended by 'wasting.' The figures must therefore be taken for what they are worth." The same qualification applies to all death-rates when an early period is compared with a later one, and it should be always borne in mind; but it is less likely to vitiate statistics which show an apparent decrease than those which show an apparent increase, as in the case of alcoholism or cancer, because in the earlier periods a large number of deaths were not classified at all. The greater diminution of consumption among females noted above is in agreement with experience in America. The figures given for a number of towns by Mr Hoffmann of the Prudential Insurance Company show that between 1871 and 1900 the death-rate fell from 361 to 274 among males, and from 369 to 183 among females.

Occupation has a marked influence on the prevalence of tuberculosis. The comparative mortality figures for various occupations compiled at the Registrar-General's Office (Supplement to 55th Annual Report) show very great differences. The following are the highest and the lowest among adult males in England and Wales:—

ADULT MALES IN ENGLAND AND WALES.

Highest.		*Lowest.*	
Tin miners	508	Coal miners (Derby, Notts)	69
Inn and hotel servants	476	Farmers	79
Unoccupied males	448	Brick and tile makers	84
Costermongers	443	Ironstone miners	90
File makers	402	Corn-millers	143
Cutlers	382	Engravers	146
Lead miners	380	Lead workers	148
Potters	333	Blacksmiths	159
Copper miners	331	Carpenters and shopkeepers	172
Printers	326	Bakers	185
Bookbinders	325	Butchers	195

The high incidence in the first group appears to be due to three causes: (1) Dust (file-makers, cutlers, potters, &c.); (2) exposure (costermongers and (?) miners); (3) alcoholism (inn-servants and unoccupied males). The two last classes have a high death-rate from alcoholism, as have costermongers; but a general comparison of the occupational mortality from consumption and alcoholism does not bear out the opinion expressed by Dr Brouardel at the London Congress in 1901 that there is a close connexion between them. This theory is contradicted by some of the conclusions to be drawn from the figures. Many industries show a low death-rate from alcoholism and a high one from consumption. Printers and cutlers, for instance, have a comparatively low alcoholic death-rate, butchers a very high one. The favourable position occupied by coal miners and ironstone miners is remarkable, and all the more so when contrasted with the excessive mortality among miners of tin, lead, and copper. The English experience is broadly corroborated by similar but much less complete statistics from the United States (Hoffmann), where miners (presumably coal miners) also enjoy the greatest immunity. These figures for the United States are shown in the following table:—

UNITED STATES.

Highest.		*Lowest.*	
Stone workers	431	Miners	64
Printers	394	Brakesmen	124
Glass workers	380	Sailors	145
Brass workers	376	Merchants	172
Book-keepers	358	Blacksmiths	186
Plumbers	353	Tailors	187
Salesmen	346	Carpenters	188
Hatters	345	Butchers	193
Silk workers	339	Masons	198
Cigar makers	330	Iron and steel workers	210
Potters	287	Weavers	214

The influence of dust is obvious in the first column. Dr Von Körösy has tabulated the result of seventeen years' observation in Budapest, which is an excessively tuberculous town. His figures include both males and females above fifteen years of age, and extend to 106,944 deaths. The field of observation is evidently very different from those which furnished the statistics already given. His results are: (1) *Males*—printers 606, butlers 520, shoemakers 494, dyers 493, millers 492, joiners 485, tinkers and locksmiths 484, masons 467, labourers 433, tailors 418, bakers 398, drivers 370, servants 360, carpenters 339, officials 336, butchers 333, merchants 253, innkeepers 272, lawyers 205, physicians 118, capitalists 106; (2) *Females*—servants 353, day labourers (? charwomen) 333, washerwomen 314, gardeners 269, capitalists 42. The inmates of lunatic asylums, who are classed among the "unoccupied," suffer excessively from tubercle. According to Dr Mott, pathologist to the London County Council, tubercular lesions are found in more than one-third of the bodies examined post mortem. The majority contract the disease in the asylums.

Heredity.—Medical opinion has undergone a great change with regard to the influence of heredity. The frequent occurrence of consumption among members of the same family used to be explained by assuming the existence of a tubercular "diathesis" or inherent liability to consumption which "ran in families" and was handed down from one generation to another. As the real nature of the disease was not understood, the inherited diathesis was regarded as a sort of latent or potential consumption which might develop at any time and could hardly be avoided. The children of consumptive parents had the "seeds" of the disease in them, and were thought to be doomed with more or less certainty. Great importance was therefore attached to heredity as a factor in the incidence of tuberculosis. The discovery that it is caused by a specific parasitic infection placed the question in a different light, and led to a more careful examination of the facts, which has resulted in a general and increasing tendency to minimize or deny the influence of heredity. At the Berlin Congress on Tuberculosis in 1899 Professor Virchow pronounced his disbelief in the theory on pathological grounds. "I dispute this heredity absolutely," he said. "For a course of years I have been pointing out that if we examine the bodies of infants newly born, who have had no life apart from the mother, we find no tuberculosis in them. I am convinced that what looked like tuberculosis in the newly born was none of it tuberculosis. In my opinion there is no authenticated case of tubercle having been found in a dissected newly-born infant." Observations on animals similarly tend to disprove the existence of congenital tuberculosis (Nocard). The theory that the germs may remain latent in the offspring of tuberculous parents (Baumgarten) is unsupported by evidence. The occurrence of disease in such offspring is ascribed to infection by the parents, and this view is confirmed by the fact that the incidence in consumptive families is greater on female children, who are more constantly exposed to home infection, than on the male (Squire). The statistical evidence, so far as it goes, points in the same direction. It is even denied that the children of consumptives are specially predisposed. An examination of the family history of 1000 cases by Dr Squire showed that the incidence was only about 9 per cent. higher on the children of consumptive than on those of non-consumptive parents. In view of the chances of infection at home run by the former, this small difference does not support the theory that they are particularly susceptible. Dr Maxon King of New York goes farther, and believes that a family history of tuberculosis, instead of predisposing to the disease, tends rather to confer some degree of resistance. Out of 103 fatal cases, 76 were of non-tubercular, and only 27 of tubercular parentage; and the average duration of the disease among the latter was 4·01 years, against 2·93 years among the former. The facts are interesting, but the numbers are not sufficient to warrant a decided conclusion. In the most recently published work on the subject (*Diseases of the Organs of Respiration*, by Samuel West, M.D., 1902), Dr West accepts "family predisposition" as an "essential factor in phthisis," but thinks that its influence is less important than was formerly believed, and that only an "increased vulnerability of tissues" is transmitted. The whole question is still in a fluid state, and needs further elucidation. Perhaps the tendency to emphasize infection to the exclusion of other factors has been a little overdone, just as too much stress was formerly laid on the family inheritance of disease and death.

Density of Population and Overcrowding.—Recognition of the communicability of tuberculosis has directed attention to the influence of conditions in which people live massed together in close proximity. The prevalence of the disease in large centres of population has already been noted, and the influence of aggregation is no doubt considerable; but it does not always hold good. The distribution in England and Wales does not correspond with density of population, and some purely rural districts have a very high mortality. Broadly, however, the rural counties have a low mortality, and those containing large urban populations a high one. The following are the seven highest and lowest counties; London heads the list. The density of population is expressed by figures in six grades—1 to 6—according to the number of persons per square mile; 6 represents the greatest density.

Death-rates from Consumption in English Counties, 1895–99.

Highest.			Lowest.		
Counties.	Death-rate.	Density of Population.	Counties.	Death-rate.	Density of Population.
London	176	6	Rutland	74	1
Northumberland	166	2	Westmorland	85	1
North Wales	156	1	Monmouth	94	3
Lancashire	151	6	Buckinghamshire	96	2
Hampshire	145	3	Worcestershire	98	4
South Wales	143	2	Hereford	98	1
Durham	136	5	Wiltshire	99	1

Among those with the highest death-rates is one large and purely rural area—North Wales. The others all contain large towns. Among the lowest, Worcestershire, though a populous county, contains no large towns. The density of population, as measured by the number of persons to the square mile, is misleading, as a large area might consist of one or two large towns and the rest bare country, which is somewhat the case with Northumberland. On the whole the distribution in England shows that the greatest incidence is on towns, but is not at all

confined to them. When the "crude" death-rates are corrected by reference to the age distribution, it is found that the rural population has a higher rate during youth, a lower one in later life; and that up to middle life consumption is not commoner in towns than in the country (Beevor).

A somewhat different conclusion is suggested by the following statistics of French towns prepared by Dr Lagneau. They go to show that the average incidence of tuberculosis is directly proportionate to the size of the communities.

	Death-rate from Tuberculosis.
Paris	490
Eleven towns having over 100,000 inhabitants	363
Forty-six towns having 30,000 to 100,000 inhabitants	305
Fifty towns having 20,000 to 30,000 inhabitants	288
One hundred and twenty-seven towns having 10,000 to 20,000 inhabitants	271
Three hundred and thirty-two towns having 5000 to 10,000 inhabitants	216
Ninety-five towns having under 5000 inhabitants	181

A more detailed investigation in London by the medical officer to the London County Council gave the following results:—

Phthisis, 1894–98.

Proportion of total population living more than two in a room (in tenements of less than five rooms).	Death-rates per 1000 living.				
	1894.	1895.	1896.	1897.	1898.
Districts with under 10 per cent.	1·07	1·18	1·07	1·14	1·10
,, ,, 10 to 15 ,,	1·38	1·49	1·46	1·42	1·43
,, ,, 15 to 20 ,,	1·57	1·64	1·61	1·63	1·61
,, ,, 20 to 25 ,,	1·81	1·83	1·67	1·75	1·80
,, ,, 25 to 30 ,,	2·11	2·09	2·06	2·10	2·07
,, ,, 30 to 35 ,,	2·26	2·42	2·13	2·32	2·42
,, ,, over 35 ,,	2·46	2·66	2·55	2·64	2·63

"There is therefore obviously relation between the amount of overcrowding and the phthisis death-rate. The figures do not, however, suffice to show whether the overcrowding caused phthisis; or whether the disease by adding to family expenditure or by diminishing the wage-earning power left less money available for rent, and thus brought about the overcrowding; or whether, again, overcrowding is associated with some other condition or conditions which are favourable to disease. In all probability all these circumstances have tended to produce the results shown in the table" (Shirley Murphy). Comparing phthisis with other diseases in relation to overcrowding, the same authority found that "while associated with overcrowding is a tendency of the population to die from disease generally, this tendency is especially manifested in the case of phthisis, and is not manifested in the case of every disease."

Other Conditions.—Poverty, insufficient food, and insanitary dwellings are always more or less associated with overcrowding, and it is difficult to distinguish the relative influence of these factors. An analysis of 553 deaths in Edinburgh according to rentals in 1899 gave these results: under £10, 230; from £10 to £20, 190; above £20, 106 (Littlejohn); but the corresponding population is not stated. An investigation of selected houses in Manchester gave some interesting results (Coates). The houses were divided into three classes: (1) infected and dirty; (2) infected but clean; (3) dirty but not infected; infected meaning occupied by a tuberculous person. Dust was taken from all parts of the rooms and submitted to bacteriological tests. The conclusions may be summarized thus: The effects of overcrowding were not apparent; a large cubic space was found to be of little avail if the ventilation was bad; the beneficial effects of light and fresh air were markedly shown even in the dirtiest houses; ordinary cleanliness was found not sufficient to prevent accumulation of infectious material in rooms occupied by a consumptive; no tuberculous dust was found in dirty houses in which there was no consumption. The upshot is to emphasize the importance of light and air, and to minimize that of mere dirt. This is quite in keeping with earlier investigations, and particularly those of Dr Tatham on back-to-back houses. Darkness and stuffiness are the friends of the tubercle bacillus. Another condition believed to be important is damp. A good deal of evidence has been collected on the subject in Great Britain. Sir George Buchanan, formerly medical officer to the Local Government Board, expressed the opinion that "wetness of soil is a cause of phthisis to the population living upon it. He based this conclusion on the comparative immunity enjoyed by persons living in pervious, high-lying, and sloping soils—that is, dry soils—contrasted with the opposite conditions, and on the fact that phthisis had been greatly reduced in towns where the water of the soil had been removed by drainage, and had not been reduced in towns where the soil had not been so dried. The English experience has been confirmed by observers in other countries, including Massachusetts (Bowditch), though some authorities in the United States deny that the connexion between a wet soil and consumption holds good in that country as a whole. It is not known in what manner wetness acts, whether by harbouring the bacillus or increasing susceptibility. An investigation into the relative prevalence of phthisis in Devonshire parishes, by Dr W. Gordon, showed a much greater incidence in places exposed to west and south-west winds (*i.e.*, wet winds) than in sheltered ones.

The influence of tuberculosis on animals is at present the subject of controversy and investigation. Until recently the result of research in various countries had led to a general consensus of opinion that tuberculous meat presents little danger, but that milk from tuberculous cows may convey the disease, and is particularly dangerous to children. Administrative measures of great importance to agricultural and other commercial interests had been based on that opinion, which is still generally held. But at the British Congress in 1901 it was strongly attacked by Professor Koch, who in effect denied the connexion between human and animal tuberculosis. The weight attached to the utterances of this eminent authority has led to a revision of the question, which is now being made the subject of special experiments in Germany, Great Britain, the United States, and elsewhere. In the unsettled state of the scientific evidence, to discuss the arguments would be out of place here; but it may be pointed out that primary tuberculosis of the intestinal tract, which at least throws suspicion on food, is by no means rare in Great Britain, and that no amount of negative evidence can dispose of recorded cases of accidental inoculation in human beings from bovine tuberculosis.

Prevention.—Measures for the prevention of tuberculosis may be divided into two classes: (1) general; (2) special. Great attention has been paid to the latter since the infectious nature of the disease was established. The former include all means by which the conditions of life are improved among the mass of the people. The most important of these are probably housing and food supply. The reduction of the disease recorded in England is attributed to the great changes which have gradually taken place in such conditions since, say, 1850. Wages have been raised, food cheapened, housing improved, protection afforded in dangerous trades, air spaces provided, locomotion increased, the ground and the atmosphere

have been cleaned and dried by sanitary means. In addition to these general measures, foreign admirers have pointed to a special one, in which also England has taken the lead, namely, the provision of consumption hospitals, which act by segregating a certain amount of disease. Yet all these things, beneficial as they may be, do not wholly account for the reduction, for if the records can be trusted, it was in progress before they had made any way or had even been begun. This observation, coupled with the apparently general tendency to diminution among civilized races, suggests the operation of some larger agency. The theory of acquired resistance, which has been already mentioned, would explain the diminution; and it is also in keeping with other facts, such as the great susceptibility of savage races, which have not been long exposed to tuberculosis, and the results of laboratory experiments in artificial immunity. The point is of great importance, and deserves careful attention; for if the theory be correct, the special measures for preventing tuberculosis, which are occupying so much attention, may eventually have unexpected results. Their general aim is the avoidance of infection, and they include (1) the provision of special institutions — hospitals, sanatoria, and dispensaries; (2) the prevention of spitting; (3) the notification of consumption; (4) the administrative control of tuberculosis in animals; (5) the dissemination of popular knowledge concerning the nature of the disease. (1) The sanatoria and other institutions are preventive measures, in that they involve the segregation of infected persons, but they may more properly be discussed under the head of treatment. (2) The greatest stress is laid upon the prevention of spitting, because the germs are contained in the sputum of consumptive persons, and are scattered broadcast by expectoration. The sputum quickly dries, and the bacilli are blown about with the dust. There is no question that infection is so conveyed. The Manchester scientific experiments, mentioned above, are only one series out of many which prove the infectivity of dust in the proximity of consumptive persons, and they are confirmed by actual experience. Several cases are recorded of healthy persons having contracted the disease after occupying rooms in which consumptive persons had previously lived. Inhalation is clearly the mode by which the poison most frequently gains entrance; hence the overwhelming incidence upon the lungs. It is doubtful if the bacilli are carried directly into the lungs; probably the actual seat of infection is more often the tissues of the throat at the junction of the air and food passages; but they enter with the breath. Once in the mouth they may, in susceptible persons, attack the throat and the lungs, or, being swallowed, the intestinal organs. These considerations explain the importance attached to control of the sputum. It is a legitimate inference that spitting in public is an important means of disseminating tuberculosis, though it may be noticed that international prevalence by no means corresponds with this disgusting practice which is a perfect curse in Great Britain, and far more common both there and in the United States than on the continent of Europe. Prohibition of spitting under a statutory penalty is attended with certain difficulties, as it is obviously impossible to make any distinction between tuberculous and other persons; but it has been applied in New York and elsewhere in America, and some local authorities in Great Britain have adopted bye-laws to check the practice. Another means of controlling dangerous sputa is more practicable, and probably more effective, namely, the use of pocket spittoons by consumptive persons. Convenient patterns are available, and their use should always be insisted on, both in public and in private. The most effective way of destroying the sputa is by burning. For this purpose spittoons of papier-mâché and of turf have been successfully used in the Vienna hospitals (Schrotter). When glass spittoons are used the contents can be sterilized by disinfectants and passed down the drain. (3) Notification is of great service as an aid to practical measures of prevention. It has been applied to that purpose with good results in several cities and states in America, and in some towns in Great Britain. New York has made the most systematic use of it. Voluntary notification was adopted there in 1894, and in 1897 it was made compulsory. The measures linked with it are the sanitary supervision of infected houses, the education of the people, and the provision of hospitals. In England, Manchester has led the way. Voluntary notification was adopted there in 1899: it was at first limited to public institutions, but in 1900 private practitioners were invited to notify their cases, and they heartily responded. The objects aimed at are to visit homes and instruct the household, to arrange and provide disinfection, to obtain information bearing on the modes of infection, to secure bacteriological examination of sputum, and to collect information to serve as a basis of hospital provision. Disinfection is carried out by stripping off paper, previously soaked with a solution of chlorinated lime ($1\frac{1}{2}$ oz. to the gallon), and washing the bare walls, ceiling, floor, and everything washable, with the same solution. This is found effective even in very dirty houses. In clean ones, where the patients have not been in the habit of spitting about the rooms, it is sufficient to rub the walls with bread-crumb and wash the rest with soap and water. Clothing, bedding, &c., are disinfected by steam. The advantages of these sanitary measures are obvious. Notification is no less important as a step towards the most advantageous use of hospitals and sanatoria by enabling a proper selection of patients to be made. It is compulsory throughout Norway, and is being adopted elsewhere, chiefly in the voluntary form. (4) As already explained, the question of animal tuberculosis is still *sub judice*. Its importance from the point of view of prevention lies in the probability that abdominal tuberculosis, which is a very fatal form of the disease in young children, and has not diminished in prevalence like other forms, is caused by the ingestion of tuberculous milk. Whether it be so or not, it is obviously desirable that both meat and milk should not be tuberculous, if it can be prevented without undue interference with commercial interests. Preventive measures may be divided into two classes. They may deal merely with the sale of meat and milk, or they may aim at the suppression of bovine tuberculosis altogether. The former is a comparatively easy matter, and may be summed up in the words "efficient inspection." The latter is probably impracticable. If practicable, it would be excessively costly, for in many herds one half the animals or even more are believed to be tuberculous, though not necessarily the sources of tuberculous food. Unless the danger is proved to be very much greater than there is any reason to suppose, "stamping out" may be put aside. Efficient inspection involves the administrative control of slaughter-houses, cowsheds, and dairies. The powers and regulations under this head vary much in different countries; but it would be useless to discuss them at length until the scientific question is settled, for if the reality of the danger remains doubtful, oppressive restrictions, such as the compulsory slaughter of tuberculous cows, will not have the support of public opinion. Whatever measures may be taken for the public protection, individuals can readily protect themselves from the most serious danger by boiling milk; and unless the source is beyond suspicion, parents are recommended, in

the present state of knowledge, so to treat the milk given to young children. (5) A great deal has been done in most countries for the dissemination of popular knowledge by forming societies, holding conferences and meetings, issuing cheap literature, and so forth. It is an important item in the general campaign against tuberculosis, because popular intelligence and support are the most powerful levers for setting all other forces in motion.

Treatment.—To discuss at all fully the treatment of the various forms of tuberculosis or even of consumption alone would be quite beyond the scope of this article. It must suffice to mention the more recent points. The open-air treatment of consumption has naturally attracted much attention. Neither the curability of this disease nor the advantages of fresh air are new things. Nature's method of spontaneous healing, explained above, has long been recognized and understood. There are, indeed, few diseases involving definite lesions which exhibit a more marked tendency to spontaneous arrest. Every case, except the most acute, bears signs of Nature's effort in this direction; and complete success is not at all uncommon, even under the ordinary conditions of life. Perhaps it was not always so: the ominous character popularly attributed to consumption may once have been justified, and the power of resistance, as we see it now, may be the result of acquired immunity or of the gradual elimination of the susceptible. However this may be, the natural tendency to cure is undoubtedly much assisted by the modern system of treatment, which makes pure air its first consideration. The principle was known to Sydenham, who observed the benefit derived by consumptives from horse exercise in the open air; and about 1830 George Boddington proposed the regular treatment of patients on the lines now generally recognized. The method has been most systematically developed in Germany by the provision of special sanatoria, where patients can virtually live in the open air. The example has been followed in other countries to a certain extent, and a good many of these establishments have been provided in Great Britain and elsewhere; but they are, for the most part, of a private character for the reception of paying patients. Germany has extended these advantages to the working classes on a large scale. This has been accomplished by the united efforts of friendly and philanthropic societies, local authorities, and the state; but the most striking feature is the part played by the State insurance institutes, which are the outcome of the Acts of 1889 and 1899, providing for the compulsory insurance of workpeople against sickness and old age. The sanatoria have been erected as a matter of business, in order to keep insured members off the pension list, and they are supported by the sick clubs affiliated to the institutes. They number forty-five, and can give three months' treatment to 20,000 patients in the year. The clinical and economic results are said to be very encouraging. In about 70 per cent. of the cases the disease has been so far arrested as to enable the patients to return to work.

The important features of the sanatorium treatment are life in the open air, independently of weather, in a healthy situation, rest, and abundance of food. The last has been carried to rather extravagant lengths in some institutions, where the patients are stuffed with food whether they want it or not. The sanatorium movement on the German model is rapidly extending in all countries. It should, however, be remembered that the benefits of fresh air are not confined to sanatoria. If the superstitious dread of the outer air, particularly at night, could be abolished in ordinary life, more would be done for public health than by the most costly devices for eluding microbes. Not only consumption, but the other respiratory diseases, which are equally destructive, are chiefly fomented by the universal practice of breathing vitiated air in stuffy and overheated rooms. The cases most suitable for the treatment are those in an early stage. Other special institutions for dealing with consumption are hospitals, in which England is far in advance of other countries, and dispensaries; the latter find much favour in France and Belgium. Both have their uses. Hospitals are particularly valuable for the reception of advanced cases, unsuitable for sanatoria. Of specific remedies it must suffice to say that a great many substances have been tried, chiefly by injection and inhalation, and good results have been claimed for some of them, but none has met with general acceptance. The most notable of them is Koch's tuberculin, a toxin prepared from tubercle bacilli. Three varieties have been tried. The first, announced in 1890, proved unsuccessful. The more recent preparations, known as T.O. and T.R., are said to have produced better results in consumption and lupus, but their efficacy has not been established. On the other hand, the value of tuberculin for diagnosing disease in cattle is generally recognized. Some serum preparations have also been tried, but without success. The only other specific methods of treatment that need mention are the application of light and of the Rontgen rays to lupus. Both have met with decided success. The light treatment is the invention of Professor Finsen of Denmark, who employs the concentrated actinic rays from the sun, or a special electric lamp. The latter is very elaborate and expensive, but may be replaced by more simple forms of apparatus recently devised.

Tübingen, a town of Würtemberg, Germany, on the Neckar, 45 miles by rail south by west of Stuttgart. It is the seat of the national university, which in 1900 was attended by 1544 students and had 104 professors, and the new buildings of which include the anatomical, surgical, physiological, and other medical institutes. There are also Protestant and Roman Catholic theological seminaries, chemical laboratories, a botanical garden, natural science collections, a numismatic collection, and a meteorological station. A monument to the poet Hölderlin was erected in 1881. Population (1895), 13,976; (1900), 15,323.

Tubuai. See TAHITI.

Tucson, a city of Arizona, U.S.A., capital of Pima county, on the Santa Cruz river, and on the southern overland line of the Southern Pacific Railroad, in the southern part of the territory. It is regularly laid out on a level site, and has a good water-supply. It contains smelters for gold, silver, and copper ores. It is the seat of the University of Arizona, a non-sectarian institution, opened in 1891. In 1899 this had a faculty of 16 and was attended by 133 students, 60 of whom were women. Population (1890), 5150; (1900), 7531, of whom 2352 were foreign-born and 474 coloured, including 86 negroes.

Tucumán, a province in the west of the Argentine Republic, bounded on the N. by the province of Salta, on the W. and S. by that of Catamarca, on the E. by that of Santiago, 780 miles from Buenos Aires by rail, on the Rio Salí. It has a national college, normal school, public library, hospital, theatre, &c. Official area

at the census of 1895, 8926 square miles. Population (1869), 108,953; (1895), 215,742. It is divided into twenty-one departments. In 1895 there were 9973 farms and 80,172 acres planted in cereals.

Tucumán, a city of the Argentine Republic, and capital of the province of the same name, 780 miles from Buenos Aires by rail, on the right bank of the Rio Salí. It was founded in 1565 by Diego Villarroel. It has a national college, normal school, public library, hospital, theatres, &c., and is also the head of a provincial railway running to Medina. Population (1895), 34,305.

Tudela, a town of Spain, in the province of Navarre, on the Ebro, on the Saragossa–Alsasua railway, and terminus of the Tudela to Tarazona line. The industries include distilleries, saw-mills, fruit preserves, linen. Some of the public buildings, hospitals, schools, bull-ring, and town hall are modern. Population (1887), 9213; (1897), 8748.

Tuguegarao, capital of the province of Cagayan, in Northern Luzon, Philippine Islands. It is situated on the Cagayan river, about 60 miles from the mouth, and can be reached by large steam-launches or by stern-wheel steamers of light draught. Its climate is extremely good. The rich valley of the Cagayan river is the great tobacco-producing region of the Philippines, and Tuguegarao is important for its shipments of this article. Population, 16,000.

Tula, a government of Central Russia, lying to the south of Moscow. It has an area of 11,954 square miles, and its population in 1897 was 1,432,743 (domiciled only), of whom 754,820 were women, and 166,350 lived in towns. The great proportion of women to men, 111 to 100, merely shows that as the census was taken in the winter a considerable part of the male population had left the province in search of work, chiefly as carpenters in the Black Sea provinces. The government is divided into twelve districts, the chief towns of which are Tula, Bogoroditsk (11,210), Alexin (2268), Byeleff (9567), Epifañ (4176), Efremoff (9044), Kashira (4046), Krapivna (6797), Novosil (2919), Odoyeff (4443), Tcherñ (3612), and Venev (5219). Only 2·6 per cent. of the aggregate area is considered as unavailable for culture, the remainder being distributed as follows:—peasants, 3,655,000 acres as allotments and 72,000 acres bought; nobility, 2,489,400 acres; other private landowners, 842,000 acres; Crown, towns, 161,300 acres. The forest covers about 675,000 acres. Agriculture is the chief occupation. There were in 1900 1,951,900 acres under crops, and the average yield in 1895–99 was: rye, 8,714,000 cwt.; wheat, 145,000 cwt.; oats, 6,163,000 cwt.; and barley, 42,000 cwt. —all cereals, 15,720,000 cwt. Grain is exported, but the crops are sometimes insufficient for the population, and years of famine have been experienced by parts of the province. The area under beetroot is increasing, but tobacco-culture is on the decline. The yield of potatoes in 1900 was 12,152,000 cwt. (chiefly for distilleries). Cattle-breeding is subsidiary only to agriculture, there being in 1900 356,260 horses, 320,460 horned cattle, 966,500 sheep, and 142,650 pigs in the province. Small trades and domestic industries, which have always been flourishing, have not suffered from the development of manufacturing industries as carried on in factories, though this has been great; on the contrary, several new domestic industries have been introduced. The aggregate annual return of the factories, which employ 20,600 persons, now amounts to 24,500,000 roubles; the principal establishments are machinery works, hardware factories, flour-mills, sugar works, and distilleries. Coal is extracted in seven mines (127,000 tons in 1899), as also pyrites and iron ore. Metallurgy is a growing industry. Education is on a better footing than in many other provinces of Central Russia, there being in the villages one school for each 884 inhabitants; the aggregate number of schools in 1899 was 1692, with 54,965 boys and 22,100 girls.

Tula, capital of the above province, on both banks of the Upa river, 120 miles by rail south of Moscow. It has become an industrial town of considerable importance, and its population has almost doubled since 1882, being 111,048 in 1897. It has a large imperial gun factory, a large sugar refinery, and a number of small factories and workshops for the manufacture of small-arms, bicycles, tea-urns, harmoniums, and all sorts of ironmongery; for these works more than 10,000 tons of iron, steel, and brass are imported every year. The factories employed in 1899 13,025 persons, and showed a yearly return of 10,295,000 roubles. The city is well provided with schools, and carries on a considerable trade. A number of factories have been built around it, and a variety of domestic industries are carried on in the neighbouring villages.

Tulcea, chief town of the district of the same name, Rumania, picturesquely situated on the right bank of the Danube, 42 miles from its mouth, at Sulina, on the Black Sea. It is the seat of a court of first instance. The principal commerce is in fish and grain. The population, which is extremely mixed, is composed of Rumanians, Russians, Turks, Greeks, and Jews, and numbered 18,800 in 1900. Wool is exported to France and Austria, and skins to Turkey.

Tulchin, a town of Russia, government of Podolia, district of Bratslav, 8 miles from the Zhuravlevka station of the South-western Railway. It must have been founded by the Hungarians, as is shown by the name of its suburb, Nesterwar, and suffered a great deal in the 16th and 17th centuries during the wars of the Cossacks with Poland. It was annexed to Russia in 1793. It is a depôt for grain and flour, and has several flour-mills, distilleries, tanneries, and military depôts. Population (1897), 19,202.

Tulle, chief town of the department of Corrèze, France, and a bishop's see, 60 miles east of Périgueux by the railway to Clermont-Ferrand. In addition to the national small-arms factory, it has manufactories of perfumery, leather, and breweries. Population (1901), 17,400.

Tunbridge, a town in the Tunbridge parliamentary division of Kent, England, 41 miles by rail south-east of London, with a station on the South-Eastern and Chatham Railway. Since 1894 it has been controlled by an urban district council. On the banks of the Medway, upon which the town stands, there are gunpowder mills. Wool-stapling is a considerable trade. Population (1891), 10,117; (1901), 12,736.

Tunbridge Wells, a municipal borough (since 1889), fashionable watering place, and market town of Kent, England, in the Tunbridge parliamentary division, on the South-Eastern and Chatham, and London, Brighton, and South Coast railways. The water of the celebrated chalybeate spring is of great purity. The chief industry consists in the manufacture of the noted Tunbridge ware—wood inlaid in mosaic—which is applied to numerous purposes. Amongst modern buildings are a new church (St Barnabas), erected 1890, the post office, 1897, and a drinking fountain and tower, in memory of Canon Hoare (died 1894), in 1897. Population (1881), 24,119; (1891, extended area), 29,254; (1901), 33,388.

Tungu, or Toungoo, a district in the Tenasserim division of Lower Burma; area, 6172 square miles. Population (1891), 211,784; (1901), 280,254. There were 1129 villages in the district in 1898–99, paying Rs.4,69,142 revenue. The population was in 1891 made up of Buddhists and Jains, 164,694; aborigines, chiefly Karens, 14,681; Hindus, 3488; Mahommedans, 3081; Parsis, 11; and Christians, 25,829, the great majority of whom are Karens. The total acreage of the district is 3,950,080. Of this 195,749 acres were cultivated in 1898–99, and the remainder consisted of forests, 906,405 acres; uncultivable land, 1,784,707 acres; cultivable land, 1,062,882 acres; and current fallow, 337 acres. The rainfall in 1898–99 was 74·85 inches. There are eleven railway stations in the district. Rice is the chief cultivation, but coffee cultivation has prospered sufficiently to supply the whole province with the berry. Tungu, the headquarters of the district, had a population of 19,232 in 1891. The detachment of British infantry stationed there before the annexation of Burma has been withdrawn, and its place is taken by a military police battalion.

Tunicata.—The article Tunicata in vol. xxiii. of this work was published in 1888, and although far more investigations have been carried out and published on this group of animals since that time than in any previous similar period, still no epoch-making discoveries and no fundamental changes in our conclusions and ideas have been made. The statements in the former article still hold good, except in some quite minor details. It is not so much alterations and corrections as additions to our knowledge that we have now to record.

New Forms.—It is to the great national exploring expeditions that we owe the chief additions to our knowledge of new forms of Tunicata, and of the geographical distribution of the group; but private collectors have also been active in many remote

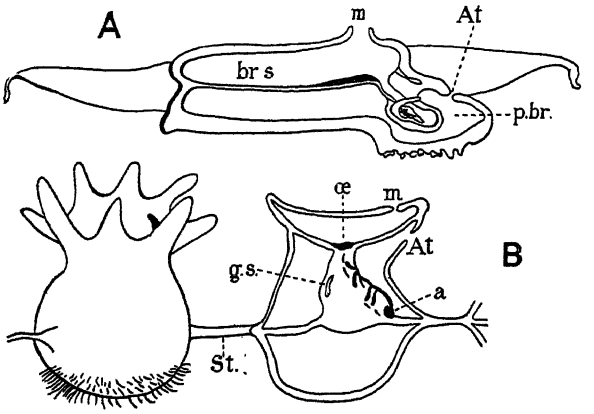

Fig. 1.—*Octacnemus.* A, Solitary form (*after Herdman*); B, aggregated form (after Metcalf). *a*, anus; *At*, atrial aperture; *br.s.*, branchial sac; *g.s.*, gill slit; *m*, mouth; *œ*, œsophagus; *p.br.*, peribranchial cavity; *st*, stolon.

parts of the world. The third and last report upon the Tunicata of the *Challenger* expedition (1888) contained the description of a new *Pyrosoma* (*P. spinosum*) of enormous size, over 4 feet in length; of several new species of *Doliolum* and *Salpa*, and of the remarkable new family Octacnemidæ (Fig. 1). Metcalf has since discovered a new species belonging to the genus *Octacnemus* (*O. patagoniensis*), in which there is an aggregated or "chain" form, consisting of a small number of individuals (Fig. 1, B) united by a slender cord composed of test and body-wall. *Octacnemus* has always been obtained from great depths (1050 to 2160 fathoms), and was described as an abyssal representative of the pelagic Salpidæ, probably fixed at the bottom. Metcalf, however, considers that the aggregated form described by him is more nearly allied to the Clavelinidæ, and that therefore *Octacnemus* does not belong to the Thaliacea. The reports on the German Plankton expedition have added considerably to our knowledge of the details of distribution, both horizontally and vertically, of the pelagic Tunicates and especially of the Salpidæ and Appendicularidæ. Several new species of *Salpa* were described by Borgert, and of Appendicularia by Lohmann. Chun (1888) also made known some remarkable deep-sea Appendicularidæ of large size from the Mediterranean. One of these species, *Megalocercus abyssorum* (30 mm. long), is the largest known Appendicularian. Seeliger and Herdman have both published new figures of transverse sections of a typical Appendicularian (*Oikopleura*). We give one

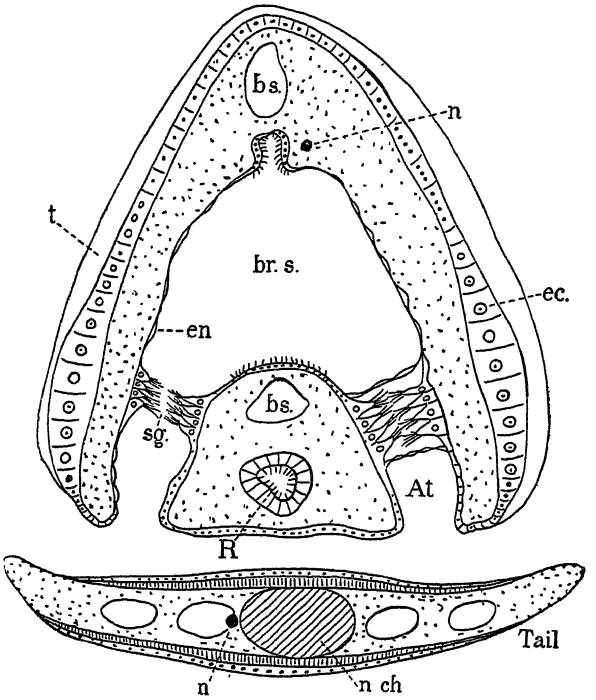

Fig. 2.—Transverse section of *Oikopleura;* anterior part of body and tail. *At*, atrial passage; *b.s.*, blood sinus; *br.s*, branchial sac (pharynx); *ec*, ectoderm; *en*, endoderm; *n*, nerve; *n.ch*, notochord; *R*, rectum; *sg*, stigma; *t*, test.

of those here (Fig. 2) as illustrating, along with the longitudinal section (Fig. 12) in the former article (vol. xxiii.), the structure of these forms. It now seems clear that the supposed segmentation or vertebration of the tail in Appendicularia is an artifact and not an indication of true metameric segmentation. Ritter has described some new Ascidians from the far north, about Bering Sea; Sluiter has been indefatigable in bringing to our knowledge new species—twenty from the Antilles, thirty from South Africa, and others from Australia and elsewhere; Gottschaldt has made known twenty-two new species from Ternate, and Michaelsen about fifteen from the Southern Ocean. Herdman has found and described some new forms from Puget Sound in the Pacific, and has drawn up a *Descriptive Catalogue* of Australian Tunicata (1899), which contains 183 species, of which 63 are described and figured for the first time. These are only a few of the considerable number of systematic papers recently published, and the number of new species which are found by such investigations shows that we must still be very far from having anything like a complete knowledge of the Tunicata of our globe. Many of the new species have revealed anatomical features of considerable interest, some of which are noted below.

As to changes in classification since the previous article, Herdman issued in 1891 a *Revised Classification*, with definitions of all groups down to species, in which the classification of the *Challenger* reports was adhered to with little change; and this has also been in the main adopted by Seeliger in his great work on the Tunicata, in Bronn's *Thier-Reich*. Sluiter has proposed as a change in classification that the families of Compound Ascidians with short undivided bodies, viz., the Botryllidæ and Polystyelidæ, should be united with Simple Ascidians under the term "Holosomata," while the remaining families of Compound Ascidians along with the Pyrosomatidæ form the "Merosomata." Herdman has suggested that these terms should be adopted in a somewhat restricted sense as indicating merely the two groups of Compound Ascidians—the Simple Ascidians being kept distinct from the Holosomata.

Anatomy and Histology.—One of the most important new facts that has been ascertained in regard to the minute structure of Tunicata is that the cells in the test or outer gelatinous tunic are derived from the mesoderm, and not, as was formerly supposed, from the ectoderm. In 1892 Kowalevsky made the remarkable discovery that cells belonging to the mesenchyme of the larva make their way through the ectoderm to the exterior during the metamorphosis, and become the first

cells of the young test. The thin structureless test of the free-swimming tailed larva previous to this has no cells. This discovery has since been corroborated and established by several investigators for other sections of the Tunicata, as, for example, by Salensky in the case of *Pyrosoma;* and it accords well with the observations made by several investigators, that in Compound Ascidians the cells of the test act as phagocytes. Later research has shown, however, that some at least of the cells in the adult test may be of ectodermal origin.

It has been shown that some of the cells in the lateral walls of the endostyle (Fig. 3) are sensory bipolar cells. Nerve-endings have also been found in the peripharyngeal bands and other parts of the wall of the pharynx. The sensory nature of the oral tentacles has been demonstrated, and that of the dorsal tubercle, long suspected, has been confirmed. Atrial tentacles have now been found in a number of the Cynthiidæ and Polystyelidæ, mainly in species which live aggregated together in masses. The so-called "otocysts" of *Salpa* have been shown by Metcalf to be glandular organs very possibly related to the neural gland of Ascidians. The function of the neural gland must still be regarded as doubtful. The secretion is formed by the degeneration and disintegration of cells proliferated from the walls of the duct or its branches, and no concretions are found. The ciliated funnel of the dorsal tubercle is a sense organ, innervated by a large nerve from the ganglion.

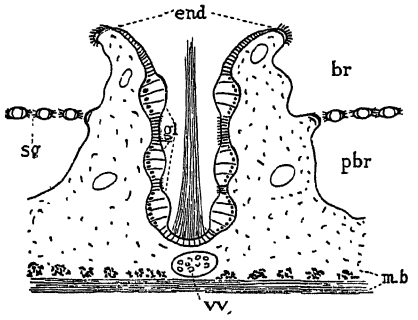

FIG. 3.—Transverse section of the endostyle of an Ascidian. *br*, branchial sac; *end*, lips of endostyle; *gl*, glandular tracts; *m.b.*, muscle bands; *p.br.*, peribranchial cavity; *sg*, stigma; *v.v.*, ventral vessel.

Physiology.—It is well known that in the family Botryllidæ, amongst Compound Ascidians, the ectodermal vessels containing blood which ramify through the common test and serve to connect the vascular systems of the various members of the colony have numerous large ovate dilatations, the ampullæ, upon their terminal twigs (Fig. 4). Various functions have been assigned to these ampullæ in the past, and Bancroft has shown that in addition to acting as storage reservoirs for blood, organs for the secretion of test matrix, and accessory organs of respiration, they are also organs for blood propulsion. The ampullæ execute co-ordinated pulsations, the co-ordination being due to variations in the blood-pressure. It was actually found that the ampullæ could keep up the circulation for some time in a portion of a colony independently of the hearts of the ascidiozooids. All the hearts in a colony of *Botryllus* contract simultaneously and in the same direction. The reversal of the circulation may be regarded as due to the engorgement of the ampullæ in the superficial parts of the colony. These when distended overcome the resistance of the heart's action, and cause it to stop and then reverse. Fig. 4 shows the ampullæ, and their relation to the rest of the colony; and Fig. 5 gives a better representation of the scheme of circulation in an Ascidian than that shown in Fig. 9 of the article in the ninth edition of this work.

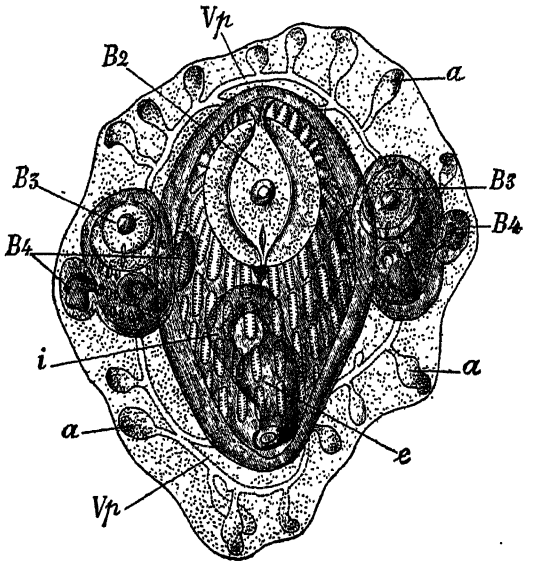

FIG. 4.—Young colony of *Botryllus*, showing buds and ampullæ (*after Pizon*). *a*, ampullæ; *b2*, *b3*, *b4*, successive generations of buds; *e*, stomach, *i*, intestine; *vp*, vessels of the test.

It will be remembered that Appendicularians have a remarkable temporary cuticular formation, probably representing the test of other Tunicata, and known commonly as the "House." This may be formed with great rapidity, attain a great size, be rapidly cast off, and again reformed. Lohmann has made a careful study of the mode of formation of this "House" from certain large ectoderm cells the "oikoplasts," and he considers that it probably fulfils the following functions:—Its complicated apparatus of passages with partial septa form a finely perforated network, through which a relatively large volume of water is strained so as to entrap microscopic food particles; it helps in locomotion by its hydrostatic effect, and it is also a protection to the animal, which may escape from enemies by throwing off the house, which is many times its own size.

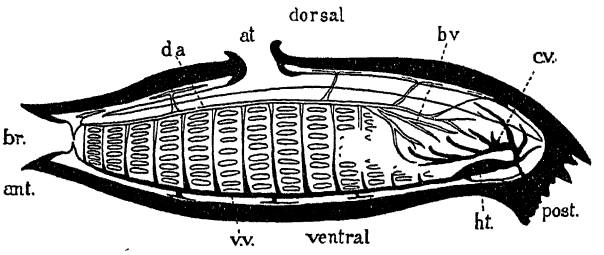

FIG. 5.—Diagram of the blood circulation in an Ascidian. The test is solid black. *at*, atrial aperture; *br*, branchial aperture; *bv*, branchio-visceral vessel; *c.v.*, cardio-visceral system; *da*, dorsal aorta; *ht*, heart; *v.v.*, ventral vessel.

Embryology and Life-History.—We owe to Castle (1896) the most complete account which has yet been given of the early stages of development in an Ascidian. His careful study of the cell lineage in *Ciona* has made it clear that some of the conflicting statements of his predecessors arose from incorrect orientation of the embryos. One of the most important of his conclusions is that the mesoderm of Ascidians, and probably that of the archaic Vertebrates, is derived from both primary layers, ectoderm and endoderm. Further, he finds that *Ciona* produces both ova and spermatozoa at the same time, but self-fertilization very rarely occurs. The eggs are laid just before dawn, and the larva is hatched during the following night. The test cells adhering to the young homogeneous test have, it is now well known, no connexion with the cells found later in the adult test. The larvæ are free-swimming for from one to several days. They avoid the light. The spermatozoon enters at the ventral hemisphere, and that point determines the median plane and the posterior end of the embryo. The ventral is the animal pole. The cleavage is from the beginning bilateral. The first cleavage plane is vertical, and separates the right and left halves of the embryo. The four smaller dorsal cells with yolk give rise to the endodermal hemisphere; the four larger, more protoplasmic cells form the ventral ectodermal hemisphere. The cells of the latter hemisphere divide more rapidly, and form the future aboral surface. When the dorsal hemisphere has twenty-two cells the ventral has fifty-four. The gastrulation is a combination of epiboly and invagination. The ventral ectoderm grows over, so as to envelop the dorsal hemisphere, while the latter sinks down and becomes saucer-shaped. In the centre of the dorsal surface ten cells form the future endoderm. Round these comes a ring of cells, the chorda-mesenchyme ring, from which the notochord and mesenchyme arise. Outside this ring is a row of cells, the neuro-muscular ring. The more anterior of these cells form the medullary plate, the more posterior the longitudinal musculature of the larva. The remainder of the cells (in the 112-cell stage) form ectoderm. By growth at the anterior end the blastopore gets pushed posteriorly, and the anterior chorda cells are covered up, and come to lie in the dorsal wall of the archenteron, sixteen cells in two rows, one over the other. The blastopore closes in the posterior part of the dorsal surface. In front of it is the medullary plate, with a continuation backwards at the sides of the blastopore. This region forms the trunk of the larva, the part posterior to it being drawn out to form the tail. The chorda cells pass back into the tail, while the mesenchyme cells shift forwards into the trunk. The muscle cells, derived from the neuro-muscular ring, lie behind the blastopore,

and form the muscles of the tail. The closure of the medullary canal takes place from the blastopore forwards, and then the nerve cord is grown over by ectoderm. After closure of the blastopore the mesenchyme cells lie as lateral masses in the trunk; later they become the blood corpuscles and the mantle cells, &c.

Castle also discusses some important theoretical questions. He points out that, in *Ciona* at least, the chorda-mesenchyme ring takes part along with endoderm in the primary invagination, and so belongs to the primary endoderm; while the rest of the mesoderm, the muscle cells of the neuro-muscular ring, are carried in by a secondary invagination, and belong to the outer layer of the young gastrula, or primary ectoderm. He considers that the chorda must be regarded as a mesodermal organ. He agrees with former observers in seeing no trace of enterocœle formation, and he doubts whether any Chordata are Enterocœla. He does not believe in distinguishing those Metazoa with a mesoderm from those with a "mesenchyme." He considers that embryology gives no support to the Annelid hypothesis as to the origin of Chordates.

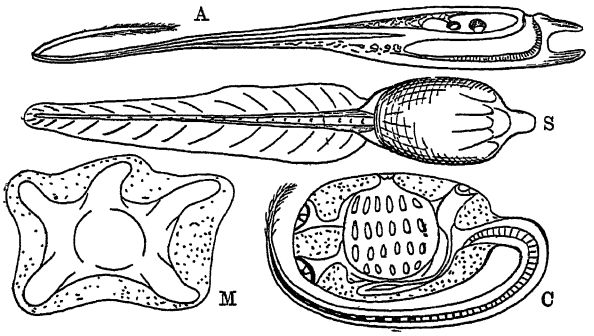

FIG. 6.—Sketches of Ascidian larvæ. A, *Ascidia*; S, *Styela*; M, *Anurella*; C, Compound Ascidian.

Fig. 6 shows a few characteristic forms of Ascidian "tadpoles," or free-swimming larvæ. A and S are typical simple Ascidians; M is the aberrant tailless form found in some Molgulidæ; and C is the larva of a typical Compound Ascidian.

A long-continued discussion as to the origin, nature, and fate of certain cells, the "testa-zellen," which make their appearance between the young embryo and its follicle (Fig. 7), has ended

FIG. 7.—Portion of mature ovum of Ascidian, showing *F*, follicle, and *f*, *r*, "test-cells." (*After Pizon.*)

in practical agreement that these small cells are derived from the follicle-cells, and have nothing to do with the test. In *Salpa*, however, certain follicle-cells enter the embryo, and perform important functions in guiding the development for a time.

Gemmation and Growth of Colonies.—A number of new observations have been made in recent years upon the budding of Compound Ascidians, some of which are very puzzling and contradictory in their results. Metschnikoff, Kowalevsky, Giard, Hjort, Pizon, Seeliger, Ritter, van Beneden, and Julin have all in turn added to our knowledge of the details of development and life-history, of the various processes of gemmation and of the formation of colonies. It is impossible as yet to reconcile all the conflicting accounts, but the following points at least seem pretty clear:—

Gemmation may be very different in its details in closely related Compound Ascidians. There are, however, two main types of budding, to one or other of which most of the described methods may be referred. There is first the "stolonial" or "epicardiac" type, seen in the Merosomata, typically in Distomidæ and Polyclinidæ, and comparable with the gemmation in Clavelinidæ, Pyrosomidæ, and Thaliacea outside this group. Secondly, there is the "parietal" or "peribranchial" type, seen in the Holosomata, typically in the Botryllidæ. The remarkable process of gemmation seen in the families Didemnidæ and Diplosomidæ may probably be regarded as a modification of the stolonial type. The double embryo in the Diplosomidæ is probably to be interpreted as precocious budding (rather than as embryonic fission), due to acceleration in development (tachygenesis). The type of budding, and even details such as the length of the stolon, have much to do with differences in the nature and appearance of the colonies produced. The stolon, which has a wall continuous with the body-wall of the parent, contains an endodermal element in the form of the so-called

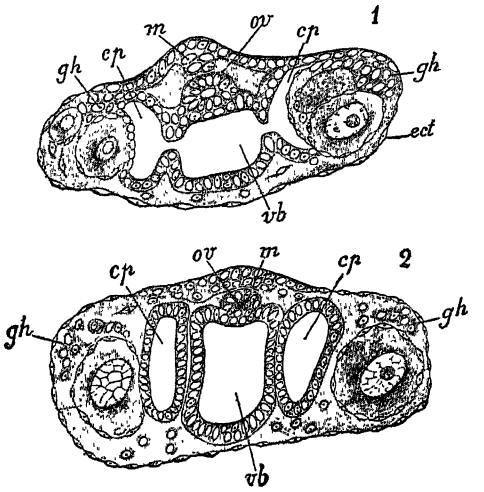

FIG. 8.—Young buds of *Botryllus* sectioned to show the separation of the branchial (*vb*) from the peribranchial (*cp*) cavities. *ov*, dorsal tube; *m*, mesoderm cells; *gh*, germ cells; *ect*, ectoderm. (*After Pizon.*)

"epicardium," and also a prolongation of the ovary, or at least a string of migrating germ-cells, so that the reproductive elements are also handed on. Still, it is clear from recent researches that the development of the bud (blastozooid) and that of the embryo (oozooid) do not proceed along parallel lines. It is impossible to harmonize the facts of gemmation with the germ-layer theory, and attempts to explain budding in Ascidians as a process of regeneration, by which the organs of the parent or their germ-layers give rise to the corresponding organs in the bud, have signally failed.

Figs. 4 and 8 show the buds in the Botryllidæ, after Pizon, who has followed day by day the changes of growth in young colonies of Botryllidæ, tracing the rise of successive generations of buds and the degeneration of their parents. The buds are parietal, arising from the walls of the peribranchial cavities (Fig. 4), and at an early period they acquire the structure shown in Fig. 8, where there are two vesicles undergoing further subdivision and differentiation, but investigators still differ as to whether the inner, which gives rise to the branchial sac and alimentary canal, is not produced along with the outer from the ectoderm of the parent.

A remarkable case of polymorphism has been found by Caullery in the buds of the Compound Ascidian *Colella*. Some of the buds have an abundant store of reserve materials in their outer layer of cells, while others are without this supply. The former are placed deeply in the stalk, develop slowly, and probably serve to regenerate the colony when the head portion has been removed or has died down. In these cases where the ectoderm has taken on the function of storing the reserve material, it is found that all the organs of the bud are formed from the cells of the endodermic vesicle.

Figs. 9 and 10 illustrate some details of structure of branchial sac and of stomach in various Ascidians which are made use of in classification, and in definitions of genera and larger groups.

Geographical Distribution.—The new forms described from Puget Sound and Alaska have drawn renewed attention to the similarity of the fauna in that region of the North Pacific and the fauna of north-west Europe. There is probably a common circumpolar Tunicate fauna which sends extensions downwards in both Atlantic and Pacific. As the result of the careful quantitative work of the German Plankton expedition, Borgert thinks that the temperature of the water has more to do with both the horizontal and the vertical distribution of pelagic Tunicata in the sea than any other factor. It is probable that the occasional phenomenal swarms of *Doliolum* which have been met with in summer in the North Atlantic are a result of the curious life-history which in favourable circumstances allows

a small number of budding forms to produce from the numerous minute buds an enormous number of the next generation. The great increase in the number of species known from nearly all seas during the last twelve or fifteen years of the 19th century

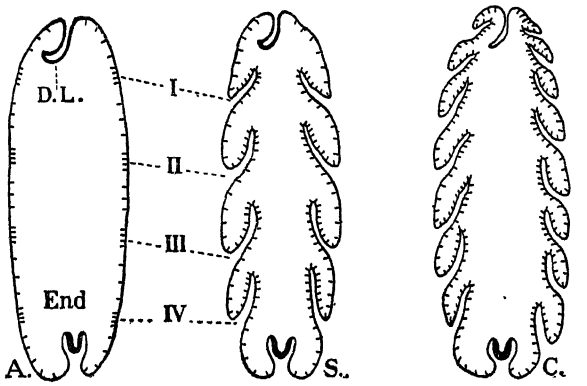

FIG. 9.—Diagrams showing transverse sections of typical branchial sacs. A, Unfolded type; S, *Styela*, with four folds on each side; C, *Cynthia*, with eight folds on one side and seven on the other; *D.L*, dorsal lamina; *End*, endostyle; I. II. &c., folds.

enables us now to form a truer estimate of the geographical distribution of the group than was possible when the *Challenger* collections were described, and shows that the Tunicata at least give no support to the "bi-polar theory" of the distribution of animals.

Finally, it may be useful to add that the volume on Tunicata, in the new edition of Bronn's *Thier-Reich*, by Prof. O. Seeliger, is now in course of publication, and if this fine work is completed in the same exhaustive and judicious manner which characterizes the first thirty parts, there can be no doubt that it will be a most authoritative work of reference on the group for years to come. (W. A. HE.)

Tunisia (REGENCY OF TUNIS). — *Geographical Boundaries and Area.*—Tunisia reaches the farthest point north of any part of Africa, Cape Blanc[1] (Ras-al-Abiadh) being in 37° 20′ N. On the south the boundary of the Tunisian Sahara is as yet undetermined, but it may be roughly placed at 32° N. This would give, therefore, a greatest length of something like 380 miles. The country lies between 11° 40′ E. and 7° 35′ E. The average length is about 300 miles, and the average breadth 150 miles; consequently the area may be estimated at 45,000 miles.[2] Geographically speaking, Tunisia is merely the eastern prolongation of the Mauritanian projection of northern Africa, of that strip of mountainous, fertile, and fairly well-watered country north of the Sahara desert, which in its flora and its fauna, and to some extent in its human race, belongs rather to Europe than to Africa. Tunisia is divided into four fairly distinct regions:—1. On the north and north-west the Aures Mountains of Algeria are prolonged into Tunis, and constitute the mountainous region of the north, which lies between the Majerda river and the sea, and also includes the vicinity of the town of Tunis and the peninsula of the Dakhelat el Mawin, which terminates in Ras Addar (Cape Bon). This first division is called by the French "the Majerda Mountains." It includes within its limits the once famous district of the "Kroumirs,"[3] a tribe whose occasional thefts of cattle across the frontier gave the French an excuse to invade Tunis in 1881. The highest point which the mountains attain in this first and northern division of Tunis is about 4125 feet, near Ain Draham in Kroumiria. The country, however, all round about Bizerta is very mountainous, though the summits do not attain a greater altitude than about 3000 feet. The district between Bizerta and the Gulf of Tunis is a most attractive country, resembling greatly the mountainous regions of South Wales. All this country is well watered by streams more or less perennial. Its vegetation is abundant, and recalls that of the more fertile districts of southern Spain and of Italy. On the higher mountains the flora has a very English character, though the actual species of plants may not be the same. 2. The central plateau region, stretching between the Majerda valley and the mountains of Gafsa. The average elevation of this country is about 2000 feet. The climate, therefore, in parts is exceedingly cold and bleak in winter, and as it is very wind-swept and parched in summer by the terrible south wind (*qibli* or "scirocco"), it is much less attractive in appearance than the favoured region on the northern littoral. Although it is almost always covered with some kind of vegetation, trees are relatively rare. A few of the higher mountains have the Aleppo pine and the juniper; elsewhere only a rare wild terebinth is to be seen. In these two regions the date palm is never met with growing naturally wild. Its presence is always due to its having been planted by man at some time or another, and therefore it is never seen far from human habitations. These central uplands of Tunis in an uncultivated state are covered with alfa or esparto grass; but they also grow considerable amounts of cereals —wheat in the north, barley in the south. The range of the Saharan Atlas of Algeria divides (roughly speaking) into two at the Tunisian frontier. One branch extends northwards up this frontier, and north-eastwards across the central Tunisian tableland, and the other continues south-eastwards between Gafsa and the salt lakes of the Jerīd. The greatest altitudes of the whole of Tunis are attained on this central tableland, where Mount Sidi Ali bu Musin ascends to about 5700 feet. About 30 miles to the south of the town of Tunis is the picturesque mountain of Zaghwan, which is approximately 4000 feet in altitude, and from whose perennial springs comes the water-supply of Tunis to-day as it did in the time of the Carthaginians and Romans. North-east of Zaghwan, and nearer Tunis, is the Jebel Resās, or Mountain of Lead, the height of which is just under 4000 feet. 3. The Sahel. This well-known Arab term for coast-belt (which in the plural form reappears as the familiar Swahili of Zanzibar) is applied to a third division of Tunis, which is the littoral region stretching from the Gulf of Hammamet to the south of Sfax. It is a region varying from 30 to 60 miles in breadth, fairly well watered and fertile. In a less marked way this fertile coast region is continued southwards in an ever-narrowing belt to the Tripolitan frontier. This region is relatively flat, in some districts slightly marshy, but the

[1] It is possible that Ras-ben-Sekka, a little to the west of Cape Blanc, may be actually the most northerly point.

[2] Or 51,000 miles, if certain Sahara districts are allotted to Tunis instead of to Algeria.

[3] The French seem systematically unable to master certain sounds foreign to their own language, or sounds which they suppose to be foreign. Thus the "w," though constantly represented in French by "ou," is continually changed by them into "v" when they transcribe foreign languages, just as the Greek χ and the German and Scottish "ch" is almost invariably rendered by the French in Algeria and Tunis as "kr." Add to this the insertion of vowel sounds where they are lacking in the Arabic, and you derive from the real word *Klumir* the modern French term of Kroumir. In like manner *sebkha*, a salt lake, is constantly written by the French as *sebkra*.

water oozing from the soil is often brackish, and in places large, shallow salt lakes are formed. Quite close to the sea, all along the coast from Hammamet to Sfax, there are great fertility and much cultivation; but a little distance inland the country has a rather wild and desolate aspect, though it is nowhere a desert until the latitude of Sfax has been passed. 4. The Tunisian Sahara. This occupies the whole of the southern division of Tunis, but although desert predominates, it is by no means all desert. At the south-eastern extremity of Tunisia there is a clump of mountainous country, the wind-and-water-worn fragments of an ancient plateau, which for convenience may be styled the Matmata tableland. Here altitudes of over 3000 feet are reached in places, and in all the upper parts of this tableland there is fairly abundant vegetation, grass and herbage with low junipers, but with no pine-trees. Fairly high mountains (in places verging on 4000 feet) are found between Gafsa and the salt lakes of the Jerīd.

These salt lakes are a very curious feature. They stretch with only two short breaks in a line from the Mediterranean at the Gulf of Gabes to the Algerian frontier, which they penetrate for a considerable distance. They are called by the French (with their usual inaccuracy of pronunciation and spelling) "chotts"; the word should really be the Arabic *shat*, the common Arab term for an inland sea, estuary, or lake. These shats, however, are, strictly speaking, not lakes at all at the present day. They are smooth, depressed areas (in the case of the largest, the Shat el Jerīd, lying a few feet below the level of the Mediterranean), which for more than half the year are expanses of dried mud covered with a thick incrustation of white or grey salt. This salt covering gives them at a distance the appearance of big sheets of water. During the winter, however, when the effect of the rare winter rains is felt, there may actually be 3 or 4 feet of water in these shats, which by liquefying the mud makes them perfectly impassable. Otherwise, for about seven months of the year they can be crossed on foot or on horseback. It would seem probable that at one time these shats (at any rate the Shat el Jerīd) were an inlet of the Mediterranean, which by the elevation of a narrow strip of land on the Gulf of Gabes has been cut off from them. It is, however, a region of past volcanic activity, and these salt depressions may be due to that cause. Man is probably the principal agent at the present day in causing these shats to be without water. All round these salt lakes there are numerous springs gushing from the sandy hillocks. Almost all these springs are at a very hot temperature, often at boiling-point. Some of them are charged with salt, others are perfectly fresh and sweet though boiling hot. So abundant is their volume that in several places they form actual ever-flowing rivers. But for the intervention of man these rivers would at all times find their way into the adjoining depressions, which they would maintain as lakes of water. But for a long period past the fresh-water streams (which predominate) have been used for irrigation to such a degree that very little of the precious water is allowed to run to waste into the lake basins; so that these latter receive only a few salt streams, which deposit on their surface the salt they contain and then evaporate. This abundant supply of fresh warm water maintains oases of extraordinary luxuriance in a country where rain falls very rarely. Perennial streams of the description referred to are found between the Algerian frontier and Gabes on the coast. The town of Gabes itself is on the fringe of a splendid oasis, which is maintained by the water of an ever-running stream emptying itself into the sea at Gabes after a course of not more than 20 miles. All this region round the shats has been called the "Jerīd" from the time of the Arab occupation. "Jerīd" means in Arabic "a palm frond," and inferentially "a palm grove." The fame of this Belad-el-Jerīd, or "Country of the Date Palms," was so exaggerated during the 17th and 18th centuries that the European geographers extended the designation from this small area in the south of Tunis to cover much of inner Africa. With this country of Jerīd may be included the island of Jerba, which lies close to the coast of Tunis in the Gulf of Gabes. The present writer believes that the date palm was really indigenous to this district of the Jerīd, as it is to countries of similar description in southern Morocco, southern Algeria, parts of the Tripolitaine, Egypt, Mesopotamia, southern Persia, and north-western India; but that north of the latitude of the Jerīd the date did not grow naturally in Mauritania, just as it was foreign to all parts of Europe, in which, as in true north Africa, its presence is due to the hand of man. To some extent it may be said that true north Africa lies to the north of this Jerīd country, which, besides its Saharan, Arabian, and Persian affinities, has a touch about it of real Africa, some such touch as may be observed in the valley of the Jordan. In the oases of the Jerīd are found several species of tropical African mammals and two or three of Senegalese birds, and the vegetation seems to have greater affinities with tropical Africa than with Europe. In fact, the country between the Matmata highlands and the strait separating Jerba from the mainland is singularly African in the character and aspect of its flora. To the south of the Jerīd the country is mainly desert—vast unexplored tracts of shifting sand with rare oases. Nevertheless, all this southern district of Tunis bears evidence of once having been subject to a heavy rainfall, which scooped out deep valleys in the original tableland, and has justified the present existence of immense water-courses—water-courses which are still, near their origin, favoured with a little water.

Rainfall.—There is no important running river in Tunis but the Majerda and its affluents. The rainfall in the first geographical division is pretty constant, and may reach a yearly average of about 22 inches. Over the second and third divisions the rainfall is less constant, and its yearly average may not exceed 17 inches. In the fourth division rain is most uncertain. Occasionally two or three years may pass without any rainfall; then may come floods after a heavy downfall of a few weeks. Perhaps if an average could be struck it would amount to 9 or 10 inches per annum.

Geology.—The region of the Sahel and all the other great plains of Tunis are of relatively recent Quaternary formation; the Kroumir country and much of the extreme north-west of Tunisia is of marine formation, and is of the Miocene and Pliocene divisions of the Tertiary epoch. Much of the interior tableland and of the ranges of hills round the shats is Cretaceous[1]; the hilly country about the central Majerda, on the central plateau (Maktar), El Kef, and farther south, and in the northern part of the Jerīd, belongs to the Upper and Lower Eocene. There are a few patches of the Lower Cretaceous all over the country.

Minerals.—Tunisia is better endowed with mineral wealth than was formerly believed. Coal has been discovered in the Kroumir country, but the principal mines at present worked in Tunis are those of lead and zinc. Zinc is chiefly found in the form of calamine. Valuable deposits of phosphates are present, chiefly in the south-west of Tunisia, round about the district of Gafsa. Marble is found in the valley of the Majerda (at Shemtu), at Jebel Ust (about 35 miles to the south of Tunis), and at Jebel Dissa, near Gabes. The marbles of Shemtu are the finest pink Numidian marbles, which were much esteemed by the Carthaginians and Romans. It has been sought to work again the ancient quarries of Shemtu, but it was found that the marble had been spoilt by ferruginous and calcareous veins. Hot and mineral springs may be almost said to constitute one of the specialities of Tunisia. They offered a singular attraction to the Romans, and their presence in remote parts of the country no doubt was often the principal cause of Roman settlement. Even at the present day their value is much appreciated by the natives, who continue to bathe in the ruined Roman baths. The principal mineral springs of medicinal value are those of Korbus and Hammam Lif (of remarkable efficacy in rheumatic and syphilitic affections and certain skin diseases), of the Jerīd and Gafsa, of El Hamma, near Gabes, and of various sites in the Kroumir country.

Flora.—The flora of Tunis is very nearly identical with that of Algeria, though it offers a few species either peculiar to itself or not found in the last-named country. On the whole its character is less Saharan than that of parts of Algeria, for the influences of the desert do not penetrate so far north in Tunis as they do in Algeria. There are very few patches of real forest outside the Kroumir country, though it is probable that in the time of the Romans the land was a good deal more covered with trees than at the present day. Some authorities, however, dispute this, in a measure, by saying that it was not naturally forested, and that the trees growing represented orchards of olives or other fruit trees planted by the Romans or Romanized Berbers. But in the Majerda Mountains there are dense primeval forests lingering to the present day, and consisting chiefly of the cork oak (*Quercus ruber*), and two other species of oak, *Quercus mirbeckii* and *Q. kermes*, the pistachio or terebinth tree, the sumach (*Rhus pentaphila*), and other species of *Rhus* which are widely spread. In the mountains of Kroumiria and the central plateau there are also the alder, the poplar, the Aleppo pine, the caroub, the tamarisk, the maple, the nettle-tree, several willows and junipers. The jujube-tree (*Zizyphus*) is found at various places along the eastern littoral. The retama shrub is met with in sandy districts, especially in the Sahara, but also right up to the north of Tunis. The wild olive, the wild cherry, two species of wild plums, the myrtle, the ivy, arbutus, and two species of holly are found in the mountains of Kroumiria, at various sites at high elevation near Tunis and Bizerta, and along the mountainous belt of the south-west which forms the frontier region between Tunis and Algeria. The present writer, riding up to these frontier mountains from the thoroughly Saharan country round Gafsa, found himself surrounded by a flora very reminiscent of Switzerland or

[1] A patch of Pliocene formation also reappears in the very centre of Tunis, to the west of Kairwan.

England. On the other hand, the flora of the *shat* region, of the south-eastern littoral, and of the Kerkena islands opposite Sfax, is thoroughly Saharan, with a dash, as it were, in places of an African element. The date palm grows wild, as has been already related, in Jerba. The only other species of palm found wild in Tunisia is the *Chamærops humilis*, or dwarf palm, which is found on the mountains of the north at no very great altitude. The wild flowers of the north of Tunis are so extremely beautiful during the months of February, March, and April as to constitute a distinct attraction in themselves.[1]

Fauna.—The fauna of Tunis at the present day is much impoverished as regards mammals, birds, and reptiles. In 1880 the present writer actually saw lions killed in the north-west of Tunis, but now the lion is said to be practically extinct in the regency, though occasional rumours of his appearance come from the Kroumir Mountains and near Feriana. Leopards of large size are still found in the north-west of central Tunisia. The cheetah lingers in the extreme south of the Jerîd; so also does the caracal lynx. The pardine lynx is found fairly abundantly in the west of Tunisia in the mountains and forest. The striped hyæna is scattered over the country sparsely. The genet and the common jackal are fairly abundant. The common ichneumon is rare. The zorilla, another purely African species, is found in the south of Tunis. The Barbary otter is present in the Majerda and in some of the salt lakes. The Tunisian hedgehog is peculiar to that country and to Algeria. There is a second species (*Erinaceus deserti*) which is common to all North Africa. In the south of Tunis, especially about the shats, the elephant-shrew (*Macroscelides*) is found, an animal of purely African affinities. Tunisia does not appear to possess the Barbary ape, which is found in Algeria and Morocco. Natives of Morocco and of the Sahara oases occasionally bring with them young baboons which they assert are obtained in various Sahara countries to the south and south-west of Tunis. These baboons appear to belong to the Nubian species, but they cannot be considered indigenous to any part of Tunis. The porcupine, and a large rodent called *Ctenodactylus*, the jerboa (two species), the hare, and various other rodents are met with in Tunisia. The wild boar inhabits the country, in spite of much persecution at the hands of "chasseurs." The forested regions shelter the handsome Barbary stag, which is peculiar to this region and the adjoining districts of Algeria. In the extreme south, in the Sahara desert, the addax antelope is still found. The hartebeest appears now to be quite extinct; so also is the leucoryx, though formerly these two antelopes were found right up to the centre of Tunis, as was also the ostrich, now entirely absent from the country. In the marshy lake near Mater (north Tunisia), round the mountain island of Jebel Ashkel, is a herd of over 50 buffaloes; these are said to resemble the domestic (Indian) buffalo of the Levant and Italy, and to have their origin in a gift of domestic buffaloes from a former king of Naples to a bey or dey of Tunis. Others again assert the buffaloes to have been there from time immemorial; in which case it is very desirable that a specimen should be submitted for examination. They are the private property of the bey, who very properly preserves them. Far down in the Sahara, to the south of Tunis, the Arabs report the existence of a wild ass, apparently identical with that of Nubia. Roman mosaics show representations not only of this ass, but of the oryx, hartebeest, and perhaps of the addax. The dorcas gazelle is still common in the south of Tunis; but perhaps the most interesting ruminant is the magnificent udad or Barbary sheep, which is found in the sterile mountainous regions of south Tunisia. The birds have been ably illustrated by Mr Whitaker in the *Ibis* magazine of the British Ornithological Union. They are, as a rule, common to the south Mediterranean region. A beautiful little bird, almost peculiar to the south of Tunis and the adjoining regions of Algeria, is a species of bunting (*Fringilla*), called by the Arabs *bu-habibi*.[2] This little bird, which is about the size of the linnet, has the head and back silvery blue, and the rest of the plumage chocolate red-brown. It is of the most engaging tameness, being fortunately protected by popular sentiment from injury. It inhabits the Jerîd, and extends thence across the Algerian frontier. Among reptiles the Egyptian cobra seems to be indigenous in the south, where also is found the dreaded horned viper. Some nine or ten other species of snakes are present, together with an abundance of lizards, including the *Varanus*, and most species of Mediterranean tortoises are represented. The coasts are very rich in fish, and the tunny fisheries of the north are one of the principal sources from which the world's supply of tunny is derived.

Population.—As regards the natives of Tunis at the present day, they belong mainly to two stocks, which we may roughly classify as the Berber and the Arab, about two-thirds being of Berber and the remaining third of Arab descent. But the Berbers of to-day are little more than an incomplete fusion of some four earlier and once independent stocks. These four divisions taken in the order of their assumed priority of invasion or habitation are: (1) the "Neanderthal" type, which is found in the districts of the shats and the adjoining Matmata tableland in the south, and in the Kroumir country of the north-west;[3] (2) ordinary Berbers, dolichocephalous, and of brown complexion, found over the greater part of Tunisia, especially in the east and south centre; (3) the short-headed Berbers, found in part of the Matmata country, part of the Sahara, the island of Jerba, the Cape Bon Peninsula, and the vicinity of Susa, Kairwan, and Sfax; (4) Berbers of a blond type, that is to say, with a tendency to brown or yellow moustaches, brown beard and head hair, and grey eyes. These are met with in the west and north-west of Tunisia, and in one patch on the coast of the Cape Bon Peninsula, near Nabeul. The Arabs of more or less unmixed descent are purely nomads. They are met with in a long strip of country south of Majerda, between the Algerian frontier and the sea-coast north of Susa, also inland, to the south-west of Susa, and near Kef; also in another long strip between the vicinity of Sfax on the north and the Jerîd on the south. The extreme south of Tunis is ranged over by Berber Tawareq[4] or Tamasheq. Berber dialects are still spoken in Tunisia in the island of Jerba, in the Matmata country, and in the Tunisian Sahara. Elsewhere to a remarkable degree the Arabic language has extinguished the Berber tongue, though no doubt in vulgar Tunisian a good many Berber words remain. A short vocabulary of the Berber spoken in the Tunisian Sahara has been published by the present writer in the *Proceedings* of the Royal Geographical Society. On the north-eastern littoral of Tunis the population is of course very mixed. The inhabitants of the Cape Bon Peninsula show evident signs of Greek blood arising from Greek invasions, which began in prehistoric times and finished with the downfall of the Byzantine empire in North Africa. The presence of the Romans, and the constant introduction of the Italians, first as slaves, and quite recently as colonists, has also added an Italian element to the north Tunisian population. But from the fact that the bulk of the Tunisian population belongs to the

To this list should also be added the common wild tulip, the Italian cyclamen, the common scarlet poppy, the fennel, wild carrot, and many varieties of thistle, some of gorgeous colouring.

[2] "Father of my friend."

[3] In this Matmata country are the celebrated Troglodytes, people living in caves and underground dwellings now, much as they did in the days when the early Greek geographers alluded to them. See "A Journey in the Tunisian Sahara," by the present writer, in the *Geographical Magazine*, June 1898.

[4] Tawareq (Tuareg) seems to be the Arab corruption of their tribal name.

Iberian section of the Berbers, and to this being no doubt the fundamental stock of most Italian peoples, the intermixture of the Italianized Berber with his African brother has not much affected the physique of the people, though it may have slightly tinged their mental characteristics.

The Phœnicians have left no marked trace of their presence; but inasmuch as they were probably of nearly the same race as the Arabs, it would not be easy to distinguish the two types. Of course Arab and Berber have mingled to some extent, though no considerable fusion of the two elements has taken place. In fact, it is thought by some French students of the country that the Arab element will probably be eliminated from Tunis, as it is the most unsettled. It is considered that these nomads will be gently pushed back towards the Sahara, leaving cultivable Tunis to the settled Berber stock, a stock fundamentally one with the peoples of Mediterranean Europe. The present population of Tunis numbers approximately 1,925,000, and consists of:—

Berbers, more or less of pure race, say . .	600,000
Arabs, ,, ,, ,, . .	500,000
Mixed Arab and Berber peoples, say . .	500,000
"Moors" (chiefly the population of the principal cities, of mixed Roman, Berber, Spanish, Moor, and Christian races, say . . .	100,000
Sudanese negroes and natives of Morocco, Tripoli, and Turkey, say	40,000
Jews (mostly natives of Tunis, indeed, some descended from families settled at Carthage before the destruction of Jerusalem) . .	60,000
Europeans (Christians)[1]	125,000

Towns.—Besides the capital, TUNIS (population about 150,000), which has been sufficiently described in vol. xxiii. of this Encyclopædia, the next most important town of Tunisia is probably Sfax, with a present population of nearly 50,000. Sfax, Susa, Kairwan, and most of the principal towns have not changed much. Bizerta (properly pronounced Ben Zert, the Roman and Greek-Carthaginian *Hippo Diarrhytus*) is situated on the banks of a narrow canal, more or less artificial, which connects the Mediterranean with a very large and deep salt lake, the Lake of Bizerta. Beyond this large salt lake (with an area of about 45 square miles) is a smaller fresh-water lake, connected with the salt lake by a narrow and impassable outlet. The French have determined to make Bizerta their second most important naval port in the Mediterranean. A new canal has been cut from the Mediterranean into the lake; but this not being wide and deep enough, it is proposed to double the width and increase the depth. A great arsenal is being established on the shores of this lake, out of the reach of any marine artillery which could be directed on it from the sea. But the canal transit of some two miles from the open sea to the inner lake will always remain such a source of risk and danger to fleets passing in and out in a hurry, that it is questionable whether Bizerta can ever attain a high position as a great naval port.

Kairwan (see also *Ency. Brit.* vol. xiii.) is a most interesting city, which still displays the Moorish colour and picturesqueness prevalent before the Europeanization of the country. Gafsa, in the south of Tunis, is well worth a visit; it is a most interesting old Roman town, with hot springs. Almost all the existing towns of Tunis were originally Roman or Romanized Berber settlements; consequently the remains of Roman buildings form a large part of the material of which their existing structures are composed.

Objects of Interest.—In the first rank of these will probably come the Phœnician and Roman antiquities. An excellent museum has been founded at Carthage by the White Fathers of Cardinal Lavigerie's mission. Here may be seen many objects illustrating Phœnician art and culture, and still more the Roman and Byzantine civilization which followed. These objects have been obtained from the site of Carthage and its vicinity. Near this museum also may be seen vast cemeteries—Byzantine, Roman, and Carthaginian (Phœnician), the order usually being in layers, with the Phœnician at the bottom. The site of Carthage itself has been hideously vulgarized. On the monticule, where formerly stood the citadel and the magnificent palace of the Roman pro-consul, have been erected (1) a cathedral in the architectural style of a Moorish music-hall;[2] (2) a hotel of the most ugly description, built by a former Belgian consul as a speculation; and (3) a "bicoque," or preposterous châlet, built by General Boulanger's son-in-law in theatrical imitation of a French "donjon." The site of the citadel of Carthage, which is seen from far and wide, and overlooks such a splendid panorama of gulf, mountain, lake, plain, and orchards, has been ruined for a time until some wise iconoclast will remove by an act of force the singularly ugly and tasteless erections which disfigure it. At the Bardo Museum, near Tunis, M. Paul Gauckler, the director of the Department of Art and Antiquities in the Tunisian Government, has assembled a magnificent collection of Carthaginian and above all Roman antiquities, especially Roman mosaics, and has also striven to illustrate the Saracenic art of Tunisia. The principal Roman ruins are the following:—the Roman aqueducts in the vicinity of Tunis; the Temple of the Waters on Zaghwan Mountain; the great reservoir near Carthage; the magnificent amphitheatre of El Djem (between Susa and Kairwan), the second or third largest in the world; the ruins of Dougga, near Teboursouk (the amphitheatre of Dougga, the ancient *Thugga*, is a magnificent spectacle); the temples, bridge, and other ruins of Sbeitla (the ancient *Suffetula*); the baths and temples of Feriana (the ancient *Thelepte*)—the whole route between Feriana in Tunisia and Tebessa in Algeria is simply strewn on both sides with Roman ruins; the old houses[3] and other ruins at and near Thala; the baths and other ruins of Gafsa; the old Roman baths at Tuzer, El Hamma, and Gabes. There is also an interesting Phœnician burial-ground near Mehdia. There are other Roman ruins, but scarcely known, in the vicinity of Beja and the country of the Mogods. In short, Tunisia is as much strewn with Roman remains as is Italy itself.

Saracenic art has perhaps not attained here the high degree it reached in western Algeria, Spain, and Egypt; still it presents much that is beautiful to see and worthy to be studied. One of the most ancient, as it is one of the loveliest fragments, strange to say, is found at Tuzer, in the Jerīd, the *mahrab* of a ruined mosque.[4] There are some very beautiful doorways to mosques and other specimens of Moorish art at Gabes. In some respects perhaps Kairwan contains what is best worth seeing in this way, but unhappily its Saracenic art treasures have suffered cruelly, firstly, in the vulgarization which followed the Turkish occupation, and, secondly, in the well-meant but blundering attempts of the Franco-Tunisian authorities to restore buildings that were falling into ruin. Tunis itself and the Bardo palace near Tunis offer some fine specimens of carved and painted ceilings, of

[1] Of recent introduction for the most part, consisting (1901) of about 72,000 Italians, 37,500 French colonists and soldiers, 12,000 Maltese, 1000 Greeks, and the remainder British, German, Austrian, &c.

[2] The idea of Cardinal Lavigerie was that if he built his cathedral as much as possible like a showy mosque, he might induce Arabs to worship there.

[3] Some of these old Roman dwellings are said still to retain their roofs.

[4] Of which a reproduction was sent to the Paris Exhibition of 1900.

tiles, and of that beautiful *naksha hadida*, or carved stucco work, which is brought to such perfection in the Alhambra. But the visible remains of Saracenic art in Tunis and its vicinity are of relatively recent date, the few mosques which might offer earlier examples not being open to inspection by Christians. It may be noted, however, as a general condition that the native towns and villages of Tunisia, where they have not been spoiled by the shocking tastelessness of Mediterranean Europe, are exceedingly picturesque, and offer exceptional attractions to the painter.

Commerce.—The commerce of Tunisia is thriving under the French protectorate, having risen from an annual total of about £1,700,000 in 1881 to £3,915,119 in 1898 and £4,163,000 in 1900. During this period the value of British trade with Tunis has also risen, though undergoing vacillations at times. It stood at considerably over £600,000 in annual value during the year 1897, and again in 1898. The principal exports are olive oil, wheat, esparto grass, barley, sponges, dates, and fish. The imports consist mainly of European manufactured goods (especially British cotton), machinery, flour, alcohol, and petroleum. The town of Tunis now being connected with the sea by a navigable canal, the port of Goletta has lost all its former importance. Excellent ports have also been made by the French at Bizerta, Susa, and Sfax.

Industries.—The principal industries are agriculture (cultivation of cereals, olives, dates, almonds, vines, figs, oranges, roses and jasmines for perfume); stock-rearing (camels, horses, cattle, sheep, goats—horses and cattle are exported to Malta in large numbers); working of minerals and phosphates; fisheries, sponge-fishing; pottery-making, leather work, silk-weaving, wool manufacture, carpet-weaving, dyeing, and perfume-making.

Railways.—The "Bône-Guelma et Prolongements" Company has constructed and works nearly all the railways of eastern Algeria and Tunisia. It has bought the little railway (Tunis-Goletta-Marsa) originally constructed by a British company in the early 'seventies and then sold to an Italian company. The Tunisian railway system consists of (1) a line from the Algerian frontier to Tunis and Bizerta, (2) a line from Tunis to Goletta and Marsa, (3) a line from Tunis to Zaghwan, (4) a line from Tunis to Hammam Lif, Nabeul, Hammamet, Susa, and Kairwan; and (5) a line from Sfax to Gafsa. All but the last-named are worked by the Bône-Guelma Company, and are well managed.

Posts and Telegraphs.—The whole of Tunisia is covered with a network of telegraph lines, and there are telephones working in most of the large towns. The telegraph system penetrates to the farthest French post in the Sahara, is connected with the Turkish system on the Tripolitan frontier and with Algeria, and by cable with Sicily, Malta, Sardinia, and Marseilles. There are about 69 telegraph stations, 11 telephone stations, and 246 post offices.

Finance.—The principal bank is the Banque de Tunisie. The coinage formerly was the caroub and piastre (the latter worth about 6d.), but in 1891 the French reformed the coinage, substituting the franc as a unit, and having the money minted at Paris. The values of the coinage are pieces of 5 and 10 centimes in bronze, of 50 centimes, 1 franc and 2 francs in silver, of 10 francs and 20 francs in gold. The inscriptions are in French and Arabic. The public debt was consolidated in 1884 into a total of £5,702,000. Since 1888 it has been converted into a loan paying 3½ per cent. interest. It is guaranteed by France. The weights and measures are those of France. The revenue for the year 1900 was £1,456,640, and the expenditure was £1,452,597. The principal sources of revenue are direct taxation, stamp and death duties, customs, port and lighthouse dues, octroi and tithes, tobacco, salt, and gunpowder monopolies, postal and telegraph receipts, and revenue from the state domains (lands, fisheries, forests, mines). The civil list paid to the bey of Tunis amounts to £36,000 per annum, and the endowment of the princes and princesses of the beylical family to £31,200 a year more.

Administration.—From a native's point of view Tunisia still appears to be governed by the bey of Tunis, his Arab ministers, and his Arab officials, the French only exercising an indirect—though a very real—control over the indigenous population (Mahommedans and Jews). But all Christians and foreigners are directly governed by the French; and the native administration is supervised by a large staff of French "contrôleurs" and their subordinates. All the departments of state have Frenchmen at their head, and the larger proportion of the bey's ministers are likewise French. France is directly represented in Tunisia by a minister Resident-General, and by an assistant Resident. The French Resident-General is the virtual viceroy of Tunisia.

History.—The following facts about the French occupation may be noted. The French having, on more or less fictitious pretexts, invaded the country in 1881 (the real cause of their invasion being an assurance given by Great Britain at the Conference of Berlin in 1878 that French predominance in Tunis would not be unfavourably regarded by Great Britain), they contented themselves at first with the occupation of various points of the so-called regency of Tunis (for Tunis, before the French occupation, was practically a fief of the Turkish empire). But in 1883 it was decided to undertake a thorough reform of the government and administration of the country, and from 1884 onwards Tunisia has been practically governed by the French minister Resident-General. Nevertheless, the Bey (Prince Sidi Muhammad, who succeeded his brother in 1882) continues to reign in a measure over his native subjects, and is the ostensible head of the Government in their eyes. On the whole French control over the country has been indirectly and wisely exercised, so that the benefits of French rule have hitherto been much more apparent than the exercise of the firm hand that has put an end to Oriental corruption. In the last two or three years of the 19th century, however, an agitation sprang up among the French "colonists" for a government which should be less that of the benevolent despotism carried on by the present triumvirate of the French minister of foreign affairs, the French minister Resident, and the Bey of Tunis, than a kind of constitutional or parliamentary control, by which the small body of French colonists are to direct and control the administration. In short, some 10,000 French settlers would like to turn what is practically analogous to an English Crown colony into one with representative institutions. Such a policy might have much to recommend it in a country like West Australia, where the native population is very sparse, but in a country like Tunis, where there are 1,800,000 Mahommedan Berbers and Arabs as compared with 125,000 Christians, such a proposition is altogether another matter, and would lead to very serious troubles, as has been the case in Algeria. Sooner or later the position of the puppet prince must become a superfluity, but Tunisia must continue to be governed despotically, wisely, and well by a single French viceroy or pro-consul, until perhaps some distant epoch when the Arabs and Mahommedanism have jointly disappeared, and the great mass of the Berber population of Roman Africa has abandoned its fatal connexion with the East, and returned to that community of European nations to which by blood and affinities it belongs.

Besides the list of works given at the conclusion of the article on TUNIS in vol. xxiii., may be added the two important articles on Tunisia in Nos. 22 and 23 of the *Revue Générale des Sciences* (30th November and 15th December 1896), Paris; and the still more important *La Tunisie Française*, in two volumes, a Government publication (Berger, Levrault et Cie., Paris, 1896). An article on the "Tunisian Sahara, the Tunisian Cave-Dwellers, and Berber Languages," &c., by the writer of the present article, was published in the *Geographical Journal* for June 1898. Other articles by the same author appeared in the *Graphic* during the years 1899, 1900, and 1902. An interesting dissertation on the question of the Berber race appears in Professor A. H. KEANE's *Man, Past and Present*. Numerous other works in English and French have been published on Tunis from the tourist's point of view, but they are for the most part lacking in accuracy or novelty of observation. *L'Afrique Romaine*, by GASTON BOISSIER, is a picturesque but somewhat superficial *aperçu* of the principal Roman ruins. *Sâlammbo*, by FLAUBERT, ought always to be read by those who visit Carthage and Tunis. It was mainly written at La Marsa, near Carthage. (H. H. J.)

Tunnelling.—Progress has been made in the methods of cooling and ventilating tunnels, in the details of drilling machines, and notably in the use of shields for sub-aqueous and soft-ground tunnels.

The Simplon railway tunnel in the Alps, near the Simplon Pass, begun in August 1898, will have a length

of about 12¼ miles, or one-third greater than the St Gothard tunnel. A novel method is introduced in the use of two parallel bores (56 feet apart, connected at intervals of 660 feet by oblique galleries), which will greatly facilitate ventilation, and tend to increased economy and rapidity of construction. One bore in the first instance, and as soon as required by the traffic the other also, will be made large enough for a single-track railway. It was expected that the first would be completed in 1904. The aggregate contract cost of

Rock tunnels.

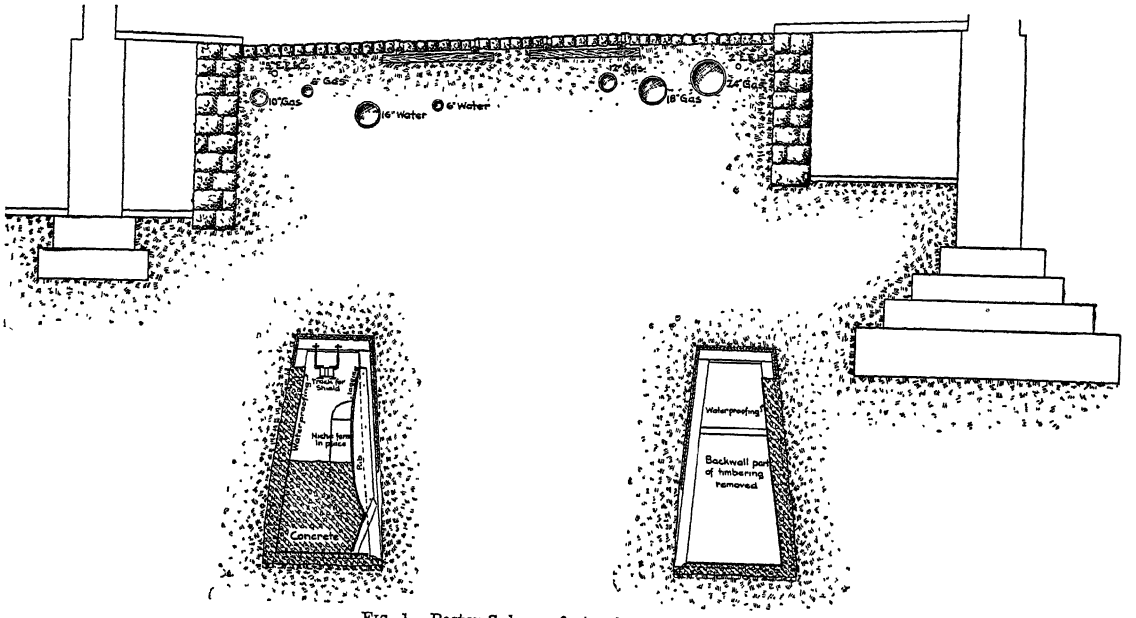

FIG. 1.—Boston Subway, first and second phases.

the two (not including track) is about £2,750,000. The rock consists of margarite, chalk, gneiss, mica, and gypsum. The rock in the middle of the tunnel will probably have a maximum natural temperature of 120° F., which during construction will be lowered to a maximum of 80° F. by very ample ventilation and cold water sprays.

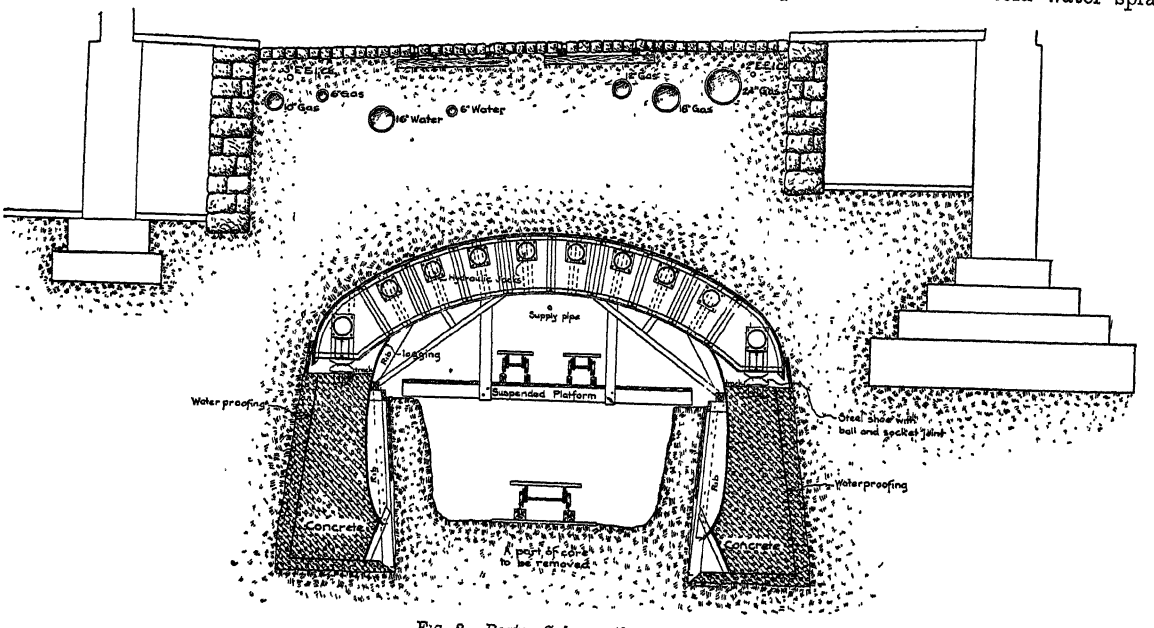

FIG. 2.—Boston Subway, third phase.

Electric propulsion of trains is proposed, to prevent vitiation of the air and to lessen the corrosion of metal, which has been so great in other tunnels. Alfred Brandt, the directing engineer on the north end, a man of great ability, whose drills have been used with much success, died in November 1899, and his place was taken by Colonel Edward Locher. The directing engineer on the south end is Carl Brandau.

Among other recent rock tunnels may be mentioned the Tequixquiac, for draining the valley of Mexico, 6 miles long, about 14 feet diameter, through sandstone and other rocks, costing about $6,760,000; the Albula, through a granite ridge of the Rhætian Alps, for a single-track narrow-gauge railroad, 3·6 miles long; tunnels on the Dore and Chinley Railway, near Totley in Derbyshire, over 3·5 miles long, largely in shale; Cowburn, over 2 miles long, shale and harder rock, each 27 feet wide and 20·5 feet high inside; the Cascade on the Great Northern Railway, state of Washington, 2·5 miles long, 24 feet high by 20 wide, through shattered granite,

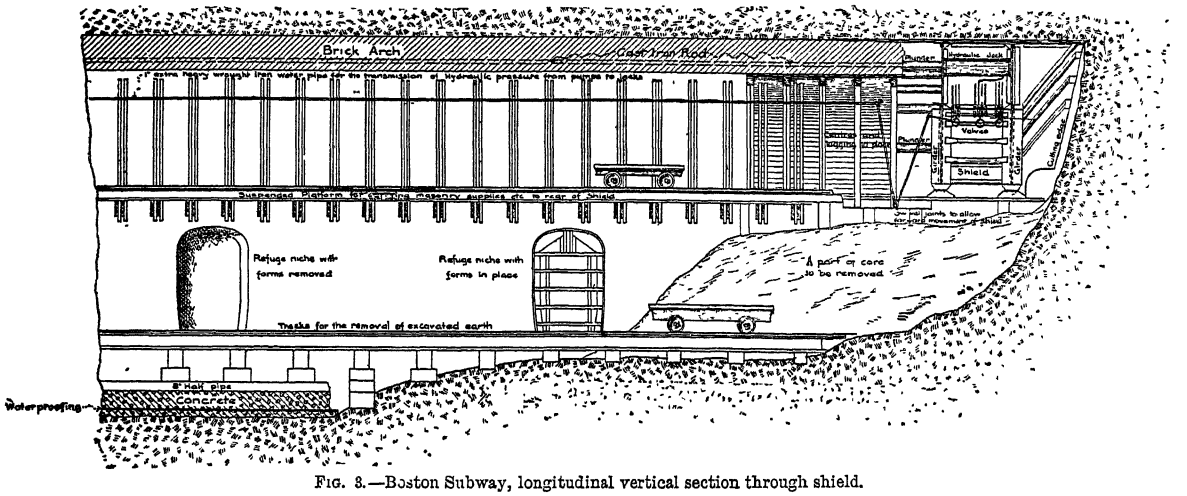

FIG. 3.—Boston Subway, longitudinal vertical section through shield.

costing about $3,000,000; the Suram, on the Trans-Caucasus Railway, for double track, 2·47 miles long, through soft rock; the tail-race tunnel for the Niagara Falls Water Power Company, 1·3 mile long, 19 feet wide and 21 feet high, through argillaceous shale and limestone, costing about $1,250,000; the narrow-gauge single-track electric railway tunnel from the Eiger Glacier to near the summit of the Jungfrau, about 6 miles long, 3·6 metres wide and 3·8 metres high; portions of the Rapid Transit Railroad in Park Avenue and Upper Broadway, New York, aggregating about 3·5 miles in length, 25 feet wide by 18 feet high, mostly through gneiss.

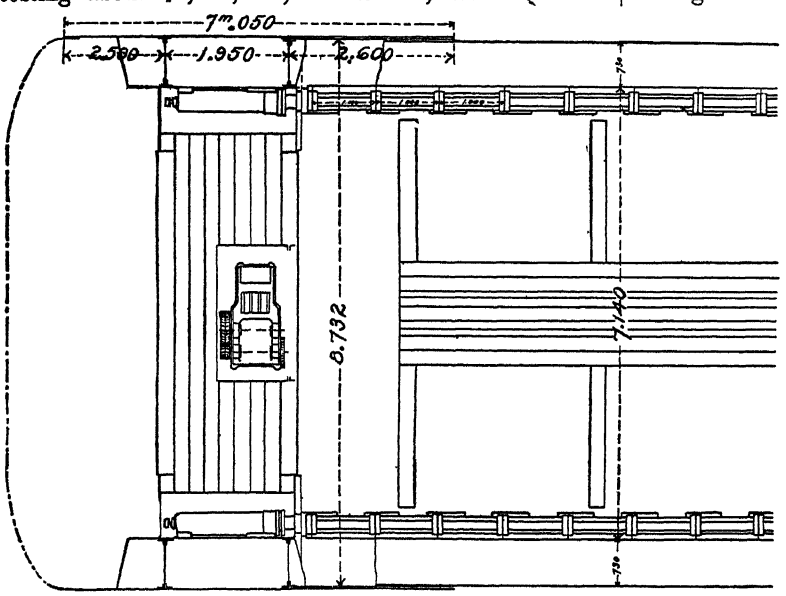

FIG. 4.—Paris Métropolitain Tunnel, longitudinal horizontal section.

Soft-ground tunnels with iron walls.

The use of compressed air in the Hudson River tunnel by D. C. Haskin (in 1880 and succeeding years), and the use of annular shields and cast-iron lined tunnel in constructing the City and South London Railway by Greathead (1886 to 1890) became widely known, and greatly influenced subaqueous and soft-ground tunnelling thereafter. The pair of tunnels for the City and South London Railway, from near the Monument to Stockwell, a distance of about 3⅛ miles, from 10 feet 2 inches to 10 feet 6 inches

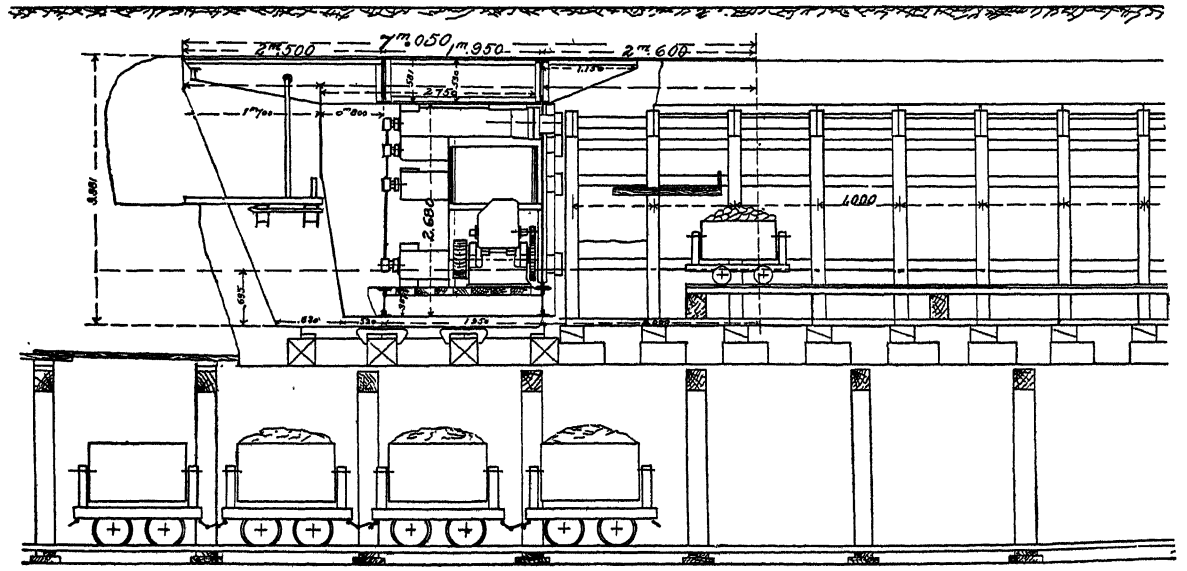

FIG. 5.—Paris Métropolitain Tunnel, longitudinal vertical section.

interior diameter, were constructed mostly in clay and without the use of compressed air, except for a comparatively short distance through water-bearing gravel. In this gravel a timber heading was made, through which the shield was pushed. The reported total cost was £840,000. Among the tunnels constructed after the City and South London work was well advanced, lined with cast-iron segments, and constructed by means of annular shields and the use of compressed air, were a further extension of the Hudson River tunnel, through silt, 2000 feet, between 1888 and 1891, when work again stopped for lack of funds; the St Clair, from Sarnia to Port Huron, 1889–90, through clay, and for a short distance through water-bearing gravel, 6000 feet, 18 feet internal diameter; and the notable Blackwall tunnel under the Thames, through clay and several hundred feet of water-saturated gravel, 1892–97, about 3116 feet long, 24 feet 3 inches in internal diameter; the shield, 19 feet 6 inches long, contained a bulkhead with movable shutters and other important features foreshadowed in Baker's proposed shield (see *Ency. Brit.* vol. xxiii. p. 625). Numerous tunnels of small diameter have been similarly constructed in London and Glasgow for electric and cable ways, &c., one under the Mersey above Liverpool for water-pipes, one under the East River in New York for gas-pipes, several for sewers in Melbourne, and two under the Seine at Paris for sewer siphons. Shields about 23 feet diameter were used in constructing stations on the Central London Railway, and one 32 feet 4 inches in diameter and only 9 feet 3 inches long on the Clapham extension of the City and South London Railway.

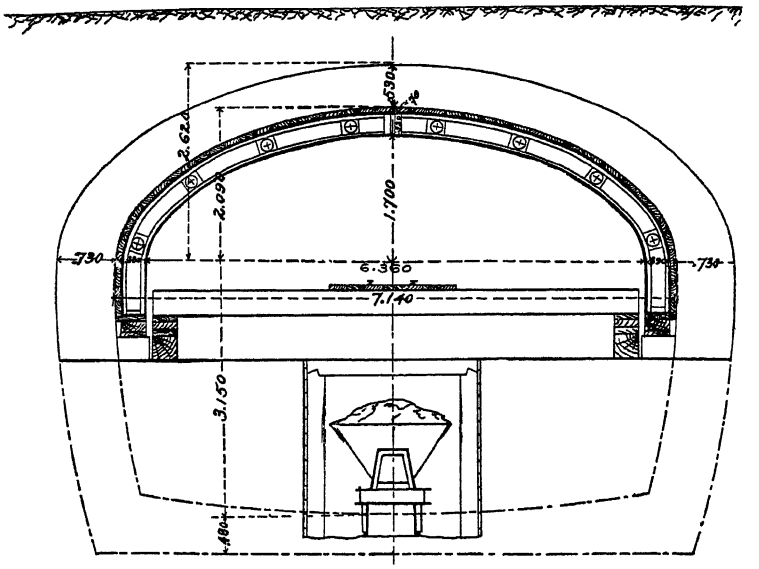

FIG. 6. Paris Métropolitain Tunnel, section through centres.

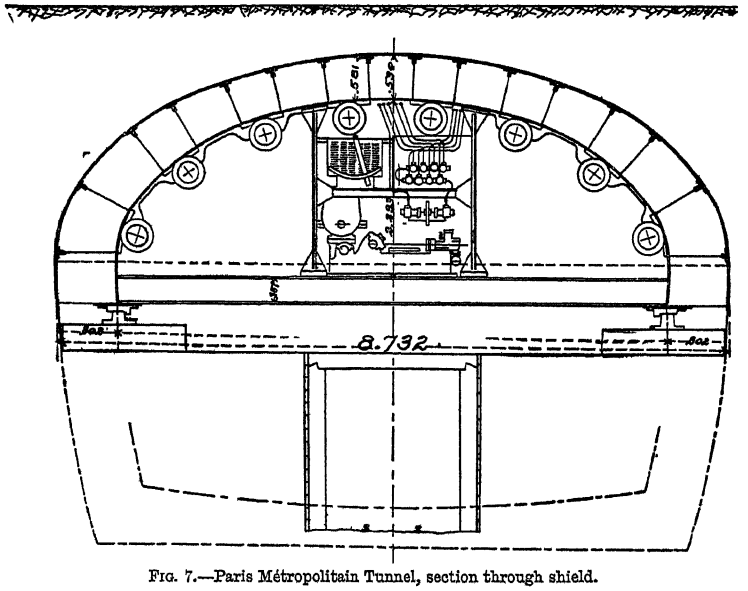

FIG. 7.—Paris Métropolitain Tunnel, section through shield.

Soft ground masonry tunnels.

The Baltimore (U.S.A.) Belt Railroad tunnel under Howard Street, about 1·4 mile in length, for a double-track railway, through sand and clay, was built mostly by the crown-bar method of timbering, in 1890–93; it is notable on account of an attempt to tunnel by means of a roof-shield running on side-walls previously made. In 1896 this method with a roof-shield (exterior diameter 29 feet 4 inches) was successfully used on a portion of the Boston subway on Tremont Street. Each hydraulic press of the shield reacted against a small continuous cast-iron rod imbedded in the brick arch. Among the important masonry tunnels built in Paris by the aid of roof-shields are: the Collecteur de Clichy (extra-mural), 1896–97, about 1·1 mile long, 6 metres wide, 5 metres high; the prolongation of the Orléans railway under the quays south of the Seine, between the Austerlitz station and the Quai d'Orsay, in 1898–99, interior width 8 to 9 metres, with a height of about 5 metres above the rail; and a portion of the Métropolitain railway system from the Porte de Vincennes to the Porte Maillot, with branches, 1898–1900, 7·1 metres wide, 5·2 metres high inside. In the Orléans tunnel the shields moved on side-walls previously constructed, as in Boston. In the other two they moved on timber platforms with steel rails, the under portions of the tunnels being made by underpinning. In all the shields were pushed from the strongly-braced ribs of the masonry centres. The Thirty-ninth Street sewerage tunnel in Chicago, through clay and quicksand, about 2 miles long, has an internal diameter of 20 feet. The shields are pushed from a wall 8 inches thick of oak plank surrounding the brick walls (18 inches thick) of the sewer. The East Boston tunnel, the first example of a shield-built monolithic concrete arch, from the Boston subway under the harbour to East Boston, is 1·4 mile long, of which 1 mile is to be excavated (begun October 1900) by tunnelling with roof-shields about 29 feet wide and 12 feet 6 inches long through clay containing some pockets of sand and gravel. Some 23 miles of water-works brick-lined tunnels have been built since 1864 in clay under the Great Lakes, without the use of shields, but the more recent ones with the use of compressed air. The latest Cleveland tunnel, 9 feet interior diameter, was built at the rate of 17 feet per day, and cost about $18 per foot.

See latest editions of Simm's and of Drinker's *Tunnelling*; Paris editions of Legouëz and of Philippe on *Le Bouclier*; 4th and 7th *Annual Reports Boston Transit Commission*.

(H. A. C.)

Tunstall, a market town and railway station, in the North-Western parliamentary division of Staffordshire, England, 4 miles north-west of Stoke. The Victoria Institute was erected at a cost of £15,000, and in 1891 a public free library was accommodated in the institute buildings. Public baths were opened in 1890, and a drill hall was built in 1895. There are many collieries, iron-works, and potteries in the immediate neighbourhood. Population (1891), 17,112; (1901), 19,492.

Tupper, Sir Charles, BART. (1821– ——), British colonial statesman, son of the Rev. Charles Tupper, D.D., was born at Amherst, Nova Scotia, on 2nd July 1821, and was educated at Horton Academy. He afterwards studied for the medical profession at Edinburgh University, where he received the diplomas of M.D. and L.R.C.S. In 1855 he was returned to the Nova Scotia Assembly for Cumberland county. In 1862 he was appointed, by Act of Parliament, governor of Dalhousie College, Halifax; and from 1867 till 1870 he was president of the Canadian Medical Association. Mr Tupper was a member of the Executive Council and provincial secretary of Nova Scotia from 1857 to 1860, and from 1863 to 1867. He became prime minister of Nova Scotia in 1864, and held that office until the Union Act came into force on 1st July 1867, when his Government retired. He was a delegate to Great Britain on public business from the Nova Scotia Government in 1858 and 1865, and from the Dominion Government in March 1868. Mr Tupper was leader of the delegation from Nova Scotia to the Union Conference at Charlottetown in 1864, and to that of Quebec during the same year; and to the final Colonial Conference in London, which assembled to complete the terms of union, in 1866–67. On that occasion he received a patent of rank and precedence from Queen Victoria as an executive councillor of Nova Scotia. He was sworn a member of the Privy Council of Canada, June 1870, and was president of that body from that date until 1st July 1872, when he was appointed Minister of Inland Revenue. This office he held until February 1873, when he became Minister of Customs. His colleague, Sir John A. Macdonald, the first premier of the Dominion House of Commons, resigned at the close of 1873, and Mr Tupper retired with him; but on Sir John's return to power in 1878, Mr Tupper became Minister of Public Works, and in the following year Minister of Railways and Canals. At this time he was made K.C.M.G. Mr Tupper was the author of the Public Schools Act of Nova Scotia, and had been largely instrumental in moulding the Dominion Confederation Bill and other important measures. Sir Charles represented the county of Cumberland, Nova Scotia, for thirty-two years in succession—first in the Nova Scotia Assembly, and subsequently in the Dominion Parliament until 1884, when he resigned his seat on being appointed High Commissioner for Canada in London. He was appointed by the Dominion Government Executive Commissioner for Canada to the Antwerp Exhibition of 1885 and the Colonial and Indian Exhibition of 1886, of which also he was appointed Royal Commissioner by Queen Victoria. Shortly before the Canadian Federal elections of February 1887, Sir Charles re-entered the Conservative cabinet as Finance Minister. By his efforts the Canadian Pacific Railway was enabled to float a loan of $30,000,000, on the strength of which the line was finished several years before the expiration of the contract time. He resigned the office of Finance Minister in May 1888, when he was reappointed High Commissioner for the Dominion of Canada in London. Sir Charles was designated one of the plenipotentiaries of her Majesty Queen Victoria to the Fisheries Convention at Washington in 1887, the result of which conference was the signing of a treaty in February 1888—subject to ratification—for the settlement of the matters in dispute between Canada and the United States in connexion with the Atlantic fisheries. He was created a baronet in September 1888. When the Dominion cabinet, under Sir Mackenzie Bowell, was reconstituted in January 1896 Sir Charles Tupper accepted office, and in the following April he succeeded Bowell in the premiership. On both patriotic and commercial grounds he urged the adoption of a preferential tariff with Great Britain and the sister colonies. At the general election in the ensuing June the Conservatives were severely defeated, chiefly on the question of the Manitoba Roman Catholic schools, and Sir Charles Tupper and his colleagues resigned, Sir Wilfrid Laurier becoming premier. The Conservative party now gradually became more and more disorganized, and at the next general election, in November 1900, they were again defeated. Sir Charles Tupper, who had long been the Conservative leader, sustained in his own constituency of Cape Breton his first defeat in forty years.

Tupper, Martin Farquhar (1810–1889), English writer, the author of *Proverbial Philosophy*, was born in London, 17th July 1810, being the son of Martin Tupper, a distinguished medical practitioner, who came of an old Huguenot family, another branch of which settled in the United States. He was educated at Charterhouse and Christ Church, Oxford, where he gained a prize for a theological essay, Gladstone being second to him. He was called to the bar at Lincoln's Inn, but never practised. He began a long career of authorship in 1832 with *Sacra Poesis*, and in 1838 he published *Geraldine, and other Poems*, and for fifty years was fertile in producing both verse and prose; but his name is indissolubly connected with his long series of didactic moralizings in blank verse, the *Proverbial Philosophy* (1838–67), which for about twenty-five years enjoyed an extraordinary popularity that has ever since been the cause of persistent satire on the part of literary critics. The first part was, however, a comparative failure, and N. P. Willis, the American author, took it to be a forgotten work of the 17th century. The uninspired character of Tupper's poetry is indubitable, and the critics who have made his name a butt were so far justified; but the *Proverbial Philosophy*, though now unread, was full of a perfectly genuine moral and religious feeling and frequently of apt and striking expressions, together with an easy flow of language, which accounted quite naturally for its success among readers to whom the subtleties of a higher order of poetry would never appeal. A genial, warm-hearted man, Tupper's humane instincts were generally in the right direction, and he espoused many reforming movements which deserved and obtained success. He was a patriotic Briton, an early supporter of the Volunteer movement, and did much to promote good relations with America. He was also a mechanical inventor in a small way. In 1886 he published *My Life as an Author;* and on 29th November 1889 he died at Albury, Surrey.

Turbines, Steam. See ENGINES: *Steam.*

Turgai, a province of Russian Central Asia, formerly part of the Kirghiz Steppes, now one of the four provinces of the general-governorship of the Steppes, bounded by Uralsk and Orenburg on the W. and N., Akmolinsk on the E., and Syr-darinsk and the Sea of Aral on the S. It has an area of 176,219 square miles, and its population, which was estimated at 323,110 in 1882, was 453,123 (domiciled only) in 1897, of whom 215,511 were women, and only 19,527 lived in towns. The

population is still mainly composed of Kirghiz, but Russians have immigrated in large numbers, and they were estimated at 21,600 in 1890 and about 30,000 in 1897. The province is divided into four districts, the chief towns of which are Turgai (1180), which is also the capital of the province, and stands off the caravan road from Tashkend to Orsk, Ak-tube (2840), a fort, in the district of Iletsk, Irghiz (1536), and Kustanai (14,065), in the Nikolaievsk district, a prairie town which has grown with great rapidity. Agriculture is mainly carried on by the Russian settlers in the Nikolaievsk district, where the crops (chiefly wheat and oats) do not suffer so much from droughts as they do elsewhere. But the Kirghiz are also beginning to cultivate the soil, and in 1900 there were in all 612,200 acres under cereals. The average yield in 1895–99 was: rye, 19,800 cwt.; wheat, 933,000 cwt.; oats, 226,000 cwt.; barley, 22,000 cwt.; all cereals, 1,115,000 cwt.; also 22,000 cwt. of potatoes. Cattle-breeding is the leading occupation of the Kirghiz, and in 1896 there were in the province 682,000 horses, 332,000 horned cattle, 1,605,000 sheep, about 128,000 goats, and 149,000 camels, these last being kept by the nomads both for their own personal use in moving about from place to place and for the transport of goods between Bokhara, Khiva, and Russian Turkestan. Cattle-breeding, however, suffers greatly from the snow-storms, which destroyed in 1879–80, 42 per cent. of all the herds, and in 1890–91, 48 per cent. of the horses, one-third of the horned cattle, sheep, and goats, and 22 per cent. of the camels. Considerable quantities of cattle and various animal products are exported to Orenburg, Orsk, and Troitsk, and to Ust-Ui and Zverinogolovsk, where large fairs are held. Hunting continues to keep its importance. There are a few oil-works, tanneries, and flour-mills, and among the Kirghiz the making of carpets and felt goods is widely spread. Education is a little more advanced than in the other Steppe provinces; the system of "migratory schools" has been introduced for the Kirghiz.

See YA. TALFEROFF, *The Turgai Province*, 1896; DOBROSMYELOFF, *Cattle-breeding in Turgai*, 1895 (both Russian).

(P. A. K.)

Turin, a city of northern Italy, formerly capital of Piedmont and the Sardinian states, and of Italy until the removal of the seat of government to Florence in 1865. It is now capital of the province of the same name, and headquarters of the first Italian army corps. Its geographical position is excellent: built upon alluvial soil at a short distance from the Alps, it stands upon two rivers, the Dora to the north, running from west to east, and the Po to the west, running from south to north. The area of the city is 4155 acres, and its octroi circle measures nearly 9 miles. The streets and avenues, almost all of which are straight, cut each other at right angles, forming blocks of houses called "islands." In 1899 the population numbered 366,055, including the garrison 8500 strong. The marriage returns show that only 3 per cent. of the population are unable to read or write. The birth-rate is 21·7 and the death-rate 17·57 per thousand. The average length of life is 45 years.

For administrative purposes the city is divided into two municipal police sections and into seven government districts or *mandamenti*. The military organization is proportionate in importance to the strategical position of Turin near the French frontier. There is a military arsenal with laboratories, a military academy for artillery and engineer officers, a war school, and a military hospital. Important new churches built since 1870 are: Santa Maria Ansiliatrice and San Giovanni Evangelista, both the work of the Salesian Order, founded by Dom Bosco; San Gioacchino; the Sacro Cuor di Maria, in which is preserved one of the *chefs-d'œuvre* of modern Italian sculpture, "Christ on the Cross," by Pietro Canonica; Nostro Signore della Salute, still unfinished. The finest theatres are the Reggio and the Carignano, but several minor ones exist. Four public arcades have been built, namely, the Galleria Geisser, the Galleria Subalpina, the Galleria Nazionale, and the Galleria Umberto I.; the three former in the centre of the city, and the latter in the working-class quarter of Porta Palazzo. The Po is spanned by four bridges, and the Dora by six. The principal public monuments are those to Cavour (by Dupré), to Carlo Alberto and Emanuele Filiberto (by Marochetti), to the Duke of Genoa (by Balzico), to Garibaldi (by Tabacchi), to Lamarmora (by Grimaldi), to Manin (by Vela), to Victor Emmanuel II. (by Pietro Costa). An equestrian monument to Prince Amadeus of Savoy (by Calandra) was inaugurated in May 1902. It is one of the most successful pieces of modern Italian statuary. Other important monuments are those commemorative of the Mont Cenis tunnel, and the magnificent "Standard-bearer" (by Vela) in honour of the Sardinian army. The Mole Antonelliana, built by Alessandro Antonelli, is the most important example of modern architecture in Turin. It belongs to the municipality, and is used for the Risorgimento Museum. It is the highest brick edifice in Europe, its summit being 510 feet above ground. In addition to the Royal Albertine Academy, the Turin museums and galleries include the Royal Pinacoteca, containing important works of the Piedmontese schools and Vandyck's famous picture, "The Sons of Charles I."; the Museum of Antiquities, notable for its collection of Egyptian antiquities; the Civic Museum, divided into two sections of fine arts and art applied to industry; the royal armoury, one of the most complete in Europe; the museums of zoology, geology, and mineralogy; and the museum of artillery. There are several libraries, including the national, the civic, and the royal, the latter containing a collection of 40,000 medals and coins. The Turin Observatory is situated in the Palazzo Madama, formerly the seat of the Italian Senate. In regard to education Turin holds one of the first places in Italy. Its university, attended by 2700 students, comprises all the faculties. New and splendid buildings, erected in the Valentino Gardens, include the university buildings proper, physical, chemical, anatomical, and pathological laboratories. Turin possesses, besides a school of practical engineering, an industrial museum, a school of veterinary medicine, a free school of agriculture, a botanical garden, numerous hospitals, a psychiatrical institute, an obstetrical institute, a laboratory of political economy, three lyceums, six gymnasiums, a technical institute, and six technical schools, one of which is for women. The municipal elementary schools count 701 classes with 30,000 pupils. There are 40 infant asylums. Four daily political newspapers are published in Turin, besides 130 periodicals of various kinds. Musical education is cared for by the Liceo Musicale, while fine arts and annual art exhibitions are promoted by a special society and by the Artists' Club. Sport and athletics are furthered by several cycling clubs with two velodromes, an automobile club, a zootechnical society, and a racing society; a ground for the game of pallone; a skating rink, two lawn-tennis clubs, a large rifle range, several athletic clubs, including an Alpine Club which, founded in Turin, has spread throughout Italy; a rowing club and several canoe clubs, which organize frequent regattas on the Po. There are more

than twenty lines of electric trams worked by two companies. The total length of tramway lines is about 53 miles. Nine lines of steam tramway start from the city, their length within the octroi circle being 11 miles.

The industries comprise metallurgy, machine-making, chemicals, silk and cotton weaving, tanning, and leather-working. The application of electricity is widely developed on account of the proximity of Alpine valleys rich in torrents. The number of persons employed in industries is 26,171, of whom 23,147 are adults (17,132 men and 6015 women), and 3024 minors (2487 males and 537 females).

Among the hospitals is that called by the name of its founder, Cottolengo, a vast institution providing for more than 5000 persons; there are also the Ospedale Maggiore di San Giovanni, the Ospedale Mauriziano, and many other hospitals for special diseases, as well as asylums and charitable institutions of all kinds. Few Italian cities are so well provided as Turin with institutions for the needy and afflicted. In regard to sanitation, Turin has reconstructed the old quarters in order to admit light and air to the most densely-populated parts, and is completing its sewers on the most modern systems. An artificial ice company has provided the city with meat storage rooms, a necessity of warm climates; the supply of drinking water, furnished by two aqueducts, is being increased by the addition of a third. The municipal budget for the year 1900 balanced with the revenue and expenditure of 14,164,803 lire. The principal sources of revenue are direct taxes and the octroi, which together produce more than 10,000,000 lire. Revenues derived from municipal properties and from municipal services yield 1,500,000 lire. Expenditure comprises 2,469,680 lire of general outlay, 2,354,000 lire for police and sanitation, 3,157,944 lire for public works, 1,786,940 of interest on the municipal debt, 854,710 lire of sinking fund, 2,643,895 lire for education, and 425,712 lire for worship and charity. Municipal properties are valued at 34,482,098 lire as against a debt of 33,150,771 lire, including 24,000,000 lire consolidated debt.

Though the opening of the St Gothard tunnel exercised a prejudicial influence upon the traffic of the network of railways of which Turin is the centre, by diminishing trade with France, the new agreement with the St Gothard railway and the opening of the Simplon tunnel will compensate these disadvantages. Trade has been facilitated by the opening of telephonic communication with Novara, Milan, Como, and Pinerolo. Similar communication has lately been opened with Rome, Modane, Lyons, Paris, and with the chief Swiss towns. Within the last twenty-five years of the 19th century, the activity of the Turinese succeeded in neutralizing the effect of the transfer of the capital to Florence and Rome. Since 1864 its population has nearly doubled, and the city, in virtue of its transformation into an active centre of trade and industry, has become eminently modern and progressive.

Among the surroundings of Turin the Hill of Superga (2300 feet above the sea) merits special mention. Victor Amadeus II. erected there a votive basilica in memory of the liberation of Turin from the French in 1706. King Charles Albert and other kings and princes of the Savoy dynasty are buried in the crypt. Not far from Turin are also the castles of Moncalieri, Stupinigi, Rivoli, Racconigi, Aglè, Venaria, and the ancient monastery of the Sagra di San Michele (753 metres above sea-level). The last named is interesting archæologically, and famous for its view of the Alps as far as the beginning of the Lombard plain. (A. Fe.)

Turkestan, a geographical term for a vast region in Central Asia, which, after excluding from it the Chinese province of Kulja and the Turkestan khanates of Afghanistan, may conveniently be divided into (I.) Western Turkestan, and (II.) Eastern or Chinese Turkestan.

I. Western Turkestan.

This country as a whole was fully described in the corresponding section of the article on Turkestan in the ninth edition of this work, and all that is now required is an account of the economic conditions of the various political divisions. These are:—(1) the vassal states of Bokhara and Khiva; the Russian provinces of (2) Turgai, Akmolinsk, and Semipalatinsk, forming part of the general-governorship of the Steppes; (3) Semiryechensk, Syr-dariinsk, Samarkand, and Fergana, composing the general-governorship of Turkestan; and (4) the Transcaspian region. These are all treated under their respective headings, and those provinces which are included in the general-governorship of the Steppes are dealt with collectively under that head. Consequently it is only necessary here to deal collectively with the provinces comprised in the general-governorship of Turkestan. The following table shows the area and population of these at the census of 1897. It should be noted that Syr-dariinsk includes the Amu-daria district, which was formerly a separate province.

Province.	Area, Square Miles.	Domiciled Population, 1897.	Density per square Mile.
Samarkand . .	26,627	857,817	32
Fergana . . .	35,654	1,560,411	43
Semiryechensk .	152,280	990,107	7
Syr-dariinsk . .	194,853	1,479,818	7
Total . .	409,414	4,888,183	12

Notwithstanding immigration, the Russians still constitute a very small proportion of the population, except in the province of Semiryechensk, where the Cossacks, the peasants, and the artisans in towns number 130,000, and, with 10,911 Russian troops, constitute 14 per cent. of the aggregate population. The only other province containing any considerable number of Russians at all is Syr-dariinsk, where there are about 10,000 Russian settlers (less than 1 per cent. of the population). About 12,000 Russians are settled in Bokhara and about 4000 in Khiva.

There are several populous cities in Russian Turkestan. Its capital, Tashkend, in the Syr-daria province, had 156,414 inhabitants in 1897, and other cities of importance are Samarkand (54,900) in Zerafshan, Marghilan (36,592 in Old Marghilan, and 8977 in New Marghilan) in Fergana, Khojent (30,076) in Syr-daria, Kokand (82,054), Namangan (61,906), and Andijan (46,680) in Fergana.

Education.—In the way of education nearly everything has still to be done. In 1899, of middle schools, there were only four gymnasia and pro-gymnasia for boys and six for girls (346 pupils), one *real* school (50 pupils), two girls' schools of the Institutions of the Empress Marie (207 pupils), one corps of cadets, and one teachers' seminarium (148 pupils). Of primary schools there were 105, with 4305 pupils in the Russian schools, and about 95,000 pupils in 6400 Mussulman schools. A technical school and an experimental agricultural station with a school have been opened at Tashkend.

Pursuits.—Agriculture and horticulture are the main pursuits of the settled population, while the nomad Kirghiz are chiefly engaged in cattle-breeding. Both agriculture and horticulture are conducted in an excellent manner and with good results.

The only statistics available showing the area cultivated and the yield per annum are those for Semiryechensk. However, approximate estimates for the crops of 1888–89 in the four Turkestan provinces are:—rye, 136,000 cwt.; winter wheat, 6,714,000 cwt.; spring wheat, 7,534,000 cwt.; oats, 1,138,000 cwt.; millet, 2,570,000 cwt.; rice, 4,124,000 cwt. About 2,500,000 cwt. of "jugara" and some Indian corn must be added. Grain is consequently exported to Bokhara and Khiva, while the Transcaspian region has to import it. Considerable quantities of melons and all sorts of vegetables, as also various sorts of haricots and oleaginous seeds, are grown by the natives; also the sunflower and the poppy (for oil) by the Russians. Garden culture stands at a high level. Since the Russian occupation progress has been made in certain branches of agriculture, notably in cotton-growing; but though efforts are being put forth to extend the area irrigated, and though ambitious schemes have been drawn up for the irrigation of the Famine Steppe, some Russian authorities consider that the native system of irrigation, taking in an area of some 3,982,000 acres, is not so well maintained now as before the advent of the Russians. The improved results obtained in cotton-growing have

been chiefly brought about by the introduction of the American cotton-tree. At the same time a much larger area has been planted: whereas in 1883 only some 1300 acres were under cotton, in 1901 the trees covered nearly 719,500 acres. In 1900 the crop yielded 1,083,000 cwt. in Fergana alone, and over 1,590,000 cwt. in the four provinces, besides 2,882,000 cwt. in Khiva and 1,451,000 cwt. in Bokhara; over 800,000 cwt. of dressed cotton was obtained in 1899, of which from 500,000 cwt. to 700,000 cwt. was exported. Twenty-four steam cotton-dressing works are now in operation, and ninety in which water is the motive power. Wheat and rice of better quality are now grown. Perhaps the most characteristic feature of Turkestan agriculture is the variety of crops grown other than cereals and fodder plants. Kunjut (for oil), lucerne, madder, tobacco, rice, melons, water-melons, cucumbers, onions, and fruit-trees—chiefly the apricot, plum, pistachio, mulberry, nut, and pomegranate—are all widely cultivated, and fruit and vegetables eaten with bread form a substantial part of the food of the population. Successful attempts have also been made to introduce beetroot for the making of sugar. Sericulture was formerly a very important industry, but about 1885 the silk-worms were attacked by disease, and the production of silk almost ceased. The industry is beginning to revive, and it is estimated that some 30,000 cwt. of raw cocoons are obtained annually. The vine, which was formerly grown only for its fruit (130,000 cwt. of currants, 600,000 roubles' worth, are exported annually), is being cultivated for wine also, of which about 270,000 gallons are obtained annually. Cattle-breeding is extensively carried on, and the estimates for 1898–99 give 548,000 camels, 1,581,000 horses, 78,000 donkeys, 1,571,000 horned cattle, and over 11,500,000 sheep and goats, to which 1,000,000 horses, 300,000 camels, 700,000 cattle, and 7,000,000 sheep in Bokhara must be added. Nothing has been done to develop the not inconsiderable mineral resources of Turkestan. In 1899 some naphtha and about 30,000 cwt. of asphalt were obtained in Fergana, besides some 6000 tons of coal, chiefly in Samarkand, and small quantities of gold, copper ores, and sulphur. About 600,000 cwt. of salt were raised in Turkestan and Transcaspian in 1899.

Railways.—The Transcaspian Railway now connects Turkestan with Krasnovodsk on the Caspian Sea. Its length, *viâ* Merv, Charjui on the Amu, and Bokhara to Samarkand, is 938 miles. This line has been continued to Kokan, New Marghilan, and Andijan, 328 miles, with a branch from Chermyaevo station to Tashkend, 94 miles. A line from Tashkend to Orenburg, *viâ* Perovsk, Kazalinsk, and Irghiz, is now under construction. The Transcaspian railway is of great importance to Turkestan, being the main artery for the export of raw cotton and animal products and the import of manufactured goods.

II. Eastern Turkestan.

Several explorations were made in this territory during the years 1886–92, by the Russian expeditions of Pyevtsoff, Roborovski, and Kosloff (the travelling companions of Prjevalsky, who continued his epoch-making work), the brothers Grum-Grzimailo, and the geologists Bogdanovitch and Obrucheff; Captain Younghusband, Carey, M. S. Bell, and M. A. Stein; the Swedish explorer Sven Hedin; Dutreuil de Rhyns, Bonvalot, Futterer, and several others. Owing to its position on the way to the yet unexplored plateaus of Tibet and the upper courses of the Yellow and the Blue rivers, East Turkestan has been crossed over and over again by numerous expeditions. We have accurate maps of all the inhabited parts of this territory, which was a *terra incognita* when Prjevalsky began his memorable journeys;[1] and rich collections of both the flora and the fauna of East Turkestan are now found in all the chief museums of Europe. These explorations do not alter the conceptions concerning the orography and the leading topographical features of the country. Only partial additions are consequently needed to the description given in the earlier volumes of this Encyclopædia.

Administration.—East Turkestan is now part of the Chinese province of Hsin-kiang, which comprises also the eastern Tian-shan and a portion of Dzungaria, the Bei-shan and a portion of the Nan-shan highlands, and also a strip of land on the Tibet plateau along its northern border range, including the Ayak-kum and Atjiklanes. According to G. Grum-Grzimailo, East Turkestan comprises three different *dao-tais*—the *dao-tai* of Kashgar (districts: Kashgar, Yarkand, and Khotan); of Aksu (districts, Aksu, Kucha, and Kurla-Karashar); and of Urumchi (districts: Turfan and Hami). The residence of the governor-general of the whole province is at Urumchi, and its chief towns are Kashgar (from 60,000 to 70,000 inhabitants), Yarkand (60,000), Khotan, Niya, Sa-chou; Aksu, Urumchi, Khotan, Uch-Turfan, Kunya Turfan (about 15,000 to 20,000 in the two towns, Chinese and Turkish, of this name), Kucha, Karashar, Hami, and Barkul.

Physical Features.—Both the natural and the administrative limits of East Turkestan are pretty well defined by the mountains which surround it—namely, by the western and the eastern Tian-shan in the north, the eastern border-ranges of the Pamir on the west, and the succession of border ranges of the Tibet plateau which are comprised under the rather misleading name of Kuen-lun. On the east, East Turkestan is separated from the Gobi by the Bei-shan or Pe-shan—a slightly higher terrace of the plateau which joins the Hami extremity of eastern Tian-shan to the eastern extremity of the Altyn-tagh, and the Nan-shan. This terrace has an average altitude of about 4500 feet, and is intersected by a series of parallel ranges which run east-north-east, have their base on the plateau, and reach a height of from 5500 to 7400 feet. Broad longitudinal valleys, covered with gravel and partly with the red "Gobi deposits," run between these low chains of ragged mountains, which consist of granites and crystalline rocks belonging to the Palæozoic period. Two routes leading from Hami to the Chinese town Sa-chou cross the Bei-shan, and as they are better provided with water than the more western routes, they are taken in preference to the latter.

Hashun Gobi.—The eastern portion of East Turkestan, between the Bei-shan and the Tarim river, is occupied by the Hashun (or Gashun) Gobi, or Ilkhuma—a desert which has all the characteristics of the Gobi (see Mongolia). It has been crossed by several expeditions, and consists apparently of two distinct parts—a dry and stony rolling desert, about 4000 feet high, intersected by parallel ranges of hills in the north; and a slightly lower portion in the south, separated from the former by the Kuruk-tagh escarpment. This latter portion comprises the Lob-nor and the Kum-tagh deserts, 2500 to 3500 feet high, and is covered with sand, especially in the neighbourhood of the Chinese town Sa-chou (on the Tan-ho or Dañ-ho river). We have here evidently a strip of land running from the Lob-nor eastwards, between the northern foot of the Altyn-tagh escarpment and the low escarpment of the Kuruk-tagh. The lowest portion of this land-strip is in the Khalachi, or Kara-nor, marshes, north of Sa-chou, and represents the remains of what formerly was a large lake, where now the Tan-ho (or Dañ-ho) and the Su-li-ho (or Bulundsir) rivers are lost.

East Turkestan Proper.—As to East Turkestan proper—*i.e.*, the trapezoidal plateau, 3000 to 4000 feet high, which stretches from the Tian-shan to the Altyn-tagh, and from the Pamir to the Hashun Gobi, and which is watered by the Yarkand-daria (or Tarim) and its tributaries—recent exploration has only confirmed the conception of it which was established by its first explorers, namely, that of a dreadful desert, the Takhla-makan, surrounded by a girdle of loosely-connected oases, which are disposed at the foot of the surrounding mountains. The numerous expeditions which have travelled along "the southern route"—that is, from Kashgar *viâ* Yarkand, the Khotan (Ilchi), Keriya, Niya, and Cherchen oases, and Lob-nor to Sa-chou—have fully disclosed the border-ridge character of

[1] The best small-scale map (1 : 7,500,000) is that issued in 1902 in Stieler's *Hand Atlas*, 62, by B. Domann, the orography being admirably represented.

the mountains which fringe the Tibet plateau from the north (see KUEN-LUN). At their western extremity these mountains join the system of parallel mountain ranges which are described under various names (Chung-kyr, Kilian, Kaskem, Sarikol ranges), and run in a south-east to north-west or "Himalayan" direction, fringing the Pamirs, and containing the Mustaghata peak (25,800 feet) so as to join farther on the Ulug-art range of the Tian-shan. It may be that—as the uplifting of the Himalaya took place at a relatively recent geological period—traces of a gulf of a Secondary period sea, obliterated by subsequent upheavals, will be found penetrating from the south into East Turkestan, and reaching perhaps by its head the corner formed by the Pamir and the Tibet border ranges about Yarkand. However, no traces of such an invasion of the sea during the Secondary age have been found as yet. It is now fully proved by the Russian explorers that the fossils which were found by Stoliczka in the Turug-art pass near Kashgar, and which he had described on the spot as Triassic, belonged in reality to the Devonian formation. Some doubt prevails, consequently, as regards the "chalk gryphæa" mentioned as having been found near Yanghi-hissar. On the contrary, distinct Carboniferous deposits have been found by Bogdanovitch in the south-western corner of Kashgaria, as well as in the Tibet border ranges west of Khotan. As to the supposed "Mesozoic and Tertiary transgressions" of which so much was written since Richthofen's journey—the sea being supposed to have invaded East Turkestan and the Gobi during the Secondary and the Tertiary periods—no traces whatever of these theoretical transgressions have been found in East Turkestan any more than they have been found in the Gobi (see MONGOLIA). The red marls, sandstones, and often unstratified or loosely stratified conglomerates, or gravels, which are found in the deserts of East Turkestan as well as of the Gobi, must have, in all probability, a *continental* origin, and they were deposited either during the Glacial period or in Post-Tertiary lakes.

The "northern route"—which leads through the succession of oases situated at the southern foot of the western Tian-shan (Kashgar, Uch-Turfan, Aksu, Bai, and Kucha), and the eastern Tian-shan (Korla, Karashar, with Lake Bagrach-kul, Kunya, Turfan, Lukchun, Pichan, and Hami)—has been equally well explored, as well as the mountains to the north of it. It is now known that in western Tian-shan the Kokshal-tau range (Tian-shan range on some Russian maps), which on the south-east borders the Tian-shan plateaus, or *syrts*, and faces the plains of East Turkestan, runs due south-west, from the snow-clad Khan Tengri (24,000 feet) to the passes Bedel and Terek-davan. This mighty range gives origin to large glaciers on both its north-western and south-western slopes (Semenoff's, Mushketoff's, the group Inylchek on the former, and Savabtsi and Djaparlyk on the latter); and it has the parallel ranges of Boz-tagh on the south-east and Kirghiznyn-Alatau on the north-west.[1]

Eastern Tian-shan.—As to the eastern Tian-shan, its complicated structure is not yet quite clear. It seems that in its western portion, from Peak Khan Tengri to the meridian of Urumchi, it is a mere continuation of the western Tian-shan ranges and *syrts* (high plateaus). The Terskei and the Narat mountains have, indeed, a north-easterly direction. However, about Urumchi they meet with the Boro-khoro (or Iren-kabirga) mountains which come from the west-north-west, running from Kopal to Lake Bagratch-kul (with the small parallel range Kok-tekke farther south). These mountains evidently belong to a different, perhaps more recent, system of upheavals. The Barkul mountains, at the eastern extremity of the eastern Tian-shan, have the same direction—they run west-north-west to east-south-east, and are continued farther east by a range of low hills which join the extremity of the Chinese Altai. As to the intermediate space, from Urumchi to Barkul, it is occupied by the Bogdo-ola mountains, which represent a massive upheaval composed in all probability of several chains of mountains. Granites, various crystalline slates, and fossil-bearing deposits of the Palæozoic age enter into the composition of the eastern Tian-shan. Its peaks are snow-clad, and on the Bogdo-ola group, in the north of Lukchun, the snow-line lies at a height of 12,800 feet, while the passes are from 11,500 feet (Davanchin Pass near Urumchi) to 9000 feet (opposite Hami). On both its slopes the eastern Tian-shan falls as a very stately escarpment to the plateau above which it rises. On its northern slope, in Dzungaria, the altitudes of the plains are 2400 feet at Gu-chen, 3100 feet at Urumchi, and 5000 feet at Barkul; and at the southern base we find altitudes of from 2500 to 2800 feet.

Depressions.—A very interesting depression, from 50 to 100 miles wide, covered with loess, gravel, salted clays, and occasionally marshes, runs along the southern foot of the eastern Tian-shan. Its level—3000 feet in the west and 2700 in the east—is slightly below the general level of both the Takhla-makan desert and the Hashun Gobi, whose average altitudes are from 3300 to 4000 feet. It is watered in its western portion by the Yarkand-daria, while its eastern portion was formerly drained by a river that has since dried up; and it appears altogether very probable that this depression was occupied in Post-Pliocene times by an immense lake.

Lukchun.—Another still deeper depression is found in the very heart, so to say, of the eastern Tian-shan, between these mountains and the escarpment which is known as the Chol-tagh. We see here that the 2000 feet level line, very closely followed by the 3000 feet horizontal, encircles a narrow elongated space from 10 to 40 miles wide and 340 miles long, from 88° 30′ E. to 95° E. The Kurukgol river waters it. About Hami, round Shona-nor, the bottom of this depression is only 120 feet above the sea in its lowest part, while at its western extremity, about Lukchun, its bottom sinks to the sea-level, or even below it. The Lukchun depression was discovered in 1889 by the brothers Grum-Grzimailo, and a few months later by the Pyevtsoff expedition. An accurate map of it, with levellings, has been made since by Roborovski, while a meteorological station was established near Lukchun town in 1893, and observations were made there during twenty-four consecutive months.[2] It appears from this map that a lake, Bojante-kul, surrounded by marshes which cover an elliptical space about 45 miles long and 15 miles wide, lies to the west-south-west of Lukchun, and that the surface of this space is either at or below the sea-level, the lowest spot being 370 feet below the level of the observatory. The exact level of this last cannot, of course, be determined, so long as no geometrical levelling has been made; but from a comparison of the twenty-four months' observations of the barometer at Lukchun, it can be inferred that the station was 56 feet below the sea-level, with a possible error of about ±40 feet. The most striking point is the small size of the depression. Some 30 miles east and west of Lukchun town the altitudes already are from 2500 to 3000 feet;[3] while the mountains a few miles north of Turfan rise to 5720 and 11,500 feet, and the Chol-tagh, a dozen miles south of Lake Bojante, reaches 3500 feet. Obrucheff has shown that a local subsidence of the rocks took place at Lukchun, along a narrow strip parallel to the main direction of the mountains,[4] but the extent of that subsidence not being known, we have no idea as to whether it was not purely local, and whether it would be adequate to explain the formation of the whole of the Lukchun depression, as well as the other much larger depression at the foot of the Tian-shan, whose extent has been already mentioned. Erosion must have been at work, and it is more than probable that not only an immense elongated lake formerly spread at the foot of the eastern Tian-shan, but that other lakes must have existed in its valleys. Ice must have been a powerful excavating agency in these mountains, since during the Glacial age, when the Arctic Sea covered the lowlands of western Siberia, the western Tian-shan mountains were buried under a thick layer of snow. Eastern Tian-shan can hardly have escaped glaciation, and we have, in fact, direct observation to that effect. G. Grum-Grzimailo describes immense boulders of a fine-grained grey granite, 14 to 17 feet high and up to 100 feet in circumference, which he found lying at an altitude of 3200 feet about the mouth of the Gaib gorge which descends from the Karlyk-tagh mountains (12,000 feet) of eastern Tian-shan, in the north-east of Hami. The rocks of this gorge consisted, both at this spot and higher up, of quite a different sort of granite and crystalline slates, and a succession of side moraines was seen along the walls of the gorge.

As to the present climate of the Lukchun depression, which happens to be situated in the very centre of Asia (the meteorological station was in 42° 41′ 57″ N. and 89° 42′ 28″ E.), it is typical for Central Asia: the average temperatures were for the year 56° Fahr.; for January, 17°; for July, 88°. The lowest temperature observed was as low as 4·5° Fahr., and the highest as high as 109·5° (147° in the sun). The summer is thus as hot as in the Sahara, and January as cold as at St Petersburg. The dryness of the air is extreme, and in 1894 and 1895 there were only 22 and 17 rainy days respectively, while during the year the sky was quite cloudless on 147 days.

Antiquities.—The Lukchun depression, which belongs to the Turfan oasis, and lies at the junction of the roads from China and Lob-nor to Dzungaria, is very fertile even now, owing to excellent irrigation. It was inhabited even in the remotest times, and ruins of ancient cities and monasteries abound in it. The exploration by D. Klements of the ruins of some of these monasteries, now buried in sand, has led to the discovery of extremely

interesting manuscripts, some of which are written in the Uigur language, and represent partly Buddhist religious texts, or Sanskrit texts in an Uigur transcription, and partly business documents,[1] while others are written in alphabets quite unknown to linguists. Many more important discoveries may be expected when the numerous ruins, dating from the first centuries of our era down to the 13th and even 16th centuries, are explored. The same is true concerning the oases along the Tibet border, where most remarkable discoveries have been made by M. A. Stein.[2] At Dandan-uilig, situated in the Takhla-makan desert, on Hedin's route from the Khotan-daria to the Keriya-daria, fourteen detached temples and dwelling-houses were excavated; and statues, votive offerings, and remarkable al-fresco paintings, as well as most interesting MSS., partly Sanskrit, were discovered. Most important MSS., written in Kharoshthi characters on wooden tablets and on leather, were unearthed, moreover, in the remains of some dwelling-houses on the Niya river.

Lob-nor.—In addition to what has been said in the ninth edition about the Tarim river, with its tributaries, and Lake Lob-nor (or Lop-nor), it must be noted that the discovery by Sven Hedin of lakes along that part of the Yarkand-daria where it flows south-east and south suggested to him the idea that the real Lob-nor of the Chinese was situated to the north of the great lake (Kara-koshun-kul) which was described as Lob-nor by Prjevalsky.[3] However, this view was not accepted by most geographers, and there is little doubt that the elongated lake and marshy region which spreads in the direction in which the Cherchen-daria flows—that is, towards east-north-east from the settlement of Lob (39° 28′ N. and 88° 16′ E.), and along whose eastern coast Kosloff travelled in 1898 for 190 miles—are really what now remains of the great Chinese lake.[4] In reality, it is possible that the whole of the triangular space between the Kuruk-tagh escarpment and the route of Kosloff in 1898 was once occupied by a large lake, traces of which Hedin found in 1900 along the southern foot of the Kuruk-tagh in the shape of extensive salt deposits and horizontal beds of clay, "with vast numbers of snail-shells, *Limnæa*, &c."[5] This lake is marked as an ancient bed of the Konche-daria on the map of East Turkestan in *Stieler's Atlas* by B. Domann. During this same journey Sven Hedin descended the extremely sinuous bed of the Yarkand-daria in a boat as far as Yanghi-kul, and he explored, during a subsequent visit to Lob-nor, most interesting ruins, where important manuscripts were unearthed.[6]

Takhla-makan Desert.—As to the Takhla-makan desert, it is known that it consists of an undulating region covered mostly with gravel and partly with sand, slowly uprising from 3400 feet on the Tarim, at Shah-yar, to 4000 feet in its middle parts, and to 4680 feet at Keriya. Prjevalsky and Carey, who crossed it, as also Hedin, who was nearly lost in its western part, found the journey extremely difficult on account of a want of water and fuel.

Communications.—The communications of East Turkestan with China proper are by means of three roads, one of which is known as the military road, and another is only available for carts; all three start from Hami, cross the Bei-shan, and reach the Chinese towns of An-hsi-chou and Sa-chou. A fourth road, which, however, is seldom resorted to, connects Lob-nor with Turfan. The passages across the eastern Tian-shan are numerous, but all of them reach great heights, only one lying at an altitude of 5560 feet, while the others lie at altitudes of from 7000 to 10,384 feet. Only three passes, all very difficult, lead across the western Tian-shan mountains to Russian Turkestan, the chief of them being Muz-art; the others are the Bedel (13,700 feet) and Terek-davan (12,700 feet) passes. And finally, several very difficult passes lead to the Pamir, the chief of them being Chichiklik (14,430 feet). The communications with India are still more difficult, the chief ones being the renowned pass of Kara-korum (18,500 feet), and another leading through the Raskem.

Industries.—Being composed of several oases, situated wide apart, East Turkestan offers a great variety as regards its agriculture and industries. Every oasis has its own peculiar features. Thus, the Khotan oasis is renowned for its silks, carpets, and felt goods. In Hami and Turfan the culture of the silk-worm and the fabrication of carpets are quite unknown, the distinctive feature of the latter oasis being its cotton goods. Kashgar is renowned for the dyeing of cottons, while Kucha is famed for its leather, Ak-su for its felts, metal goods, and leather, and Karashar is known for its saddlery. The East Turkestan goods are, however, considered inferior to those of Bokhara and Fergana. The system of irrigation has attained its highest perfection in the district of Turfan, where the irrigation canals are better than anywhere in Central Asia. The best gardens are found in Khotan, while the best melons come from Turfan and Hami; the former is also renowned for its raisins, rice, sorghum, kunjut (*Sesamum indicum*), and hemp. Cotton and tobacco are grown everywhere. Madder is also cultivated to some extent. East Turkestan is rich in all sorts of minerals, but their extraction continues to be very limited. Sulphur, saltpetre, and alum are obtained near Uch-Turfan and Yarkand. Jade and gold are found in the Kuen-lun mountains, lead in the west of Kashgar, where some naphtha, coal, and copper ores are also found. Some copper is extracted on the southern slopes of the Bogdo-ola mountains. Coal is found in many places at Kurla, in the Karashar, in the Turfan oasis, and to the west of Hami. Rock-salt is obtained in the east of Ak-su and in northern Turfan. But all this mineral wealth still remains untouched, and metals, as also metal goods, are imported from Russia. Cotton, leather goods, sugar, matches, and so on, as also silk stuffs, are also imported from Russia, as well as silk goods fabricated in Russian Turkestan. Tea, silver, china, opium, and various small Chinese goods are imported from China. As to the trade with India, it has nearly disappeared—only some gold brocades, colours, tea, and drugs being imported. The chief exports from East Turkestan are silver, some cottons, raw silks, felts, and carpets to Russia; dried fruit and various small goods to Dzungaria; raisins and some raw cotton to China. However, the whole country has fallen into great poverty, and both the internal and external trade are passing through a crisis. Owing to a want of meadows, cattle-breeding has never been very much developed in East Turkestan, and horses are imported from the Kirghiz and Kalmyks. Lucerne is sown, but its crops are hardly sufficient for maintaining the small number of cows. Goods are transported principally on horseback or on donkeys, camels being used only for long-distance caravans.

(P. A. K.)

Turkestan, or HAZRET, a town of Russia, in the Turkestan province of Syr-daria, on the highway from Orenburg to Tashkend, from which it is 180 miles distant. It lies on the right bank of the Syr river, 20 miles from it, at an altitude of 833 feet. It has a very old mosque of the saint Hazret-Yassavi, which attracts many pilgrims. It is now an important depôt for hides, wool, and other produce of cattle-breeding, the returns of its fairs reaching about 2,500,000 roubles a year. Population (1897), 11,592.

TURKEY.

I. Geography and Statistics.

THE Turkish or Ottoman empire comprises Turkey in Europe, Turkey in Asia, and the vilayets of Tripoli and Barca, or Bengazi, in North Africa; and in addition to those provinces under immediate Turkish rule, it embraces also certain tributary states, and certain others under foreign administration. Turkey in Europe, occupying the central portion of the Balkan Peninsula, lies between 38° 46′ and 42° 50′ N. and 19° 20′ and 29° 10′ E. It is bounded on the N.W. by Montenegro and Bosnia, on the N. by Servia and Bulgaria, on the E. by the Black Sea and the Bosphorus, on the S. by the Sea of Marmora, the Dardanelles, the Aegean Sea, and Greece, and on the W. by the Ionian and Adriatic Seas. Turkey in Asia, fronting Turkey in Europe to the south-east, and lying between 28° and 41° N. and 25° and 48° E., is bounded on the N. by the Black Sea, on the N.W. by the Bosphorus, the Sea of Marmora, and the Dardanelles, on the W. by the Aegean Sea, on the E. by Persia and Transcaucasia, and on the S. by Arabia and the Mediterranean. By the treaty of peace with Greece, 4th December 1897, about 180 square miles of Greek territory were ceded to Turkey—about 19 square miles being added to the vilayet of Janina, and the remainder to the independent district of Selfidje.

Population.—The following table is based, as regards European Turkey, on Petermann's *Die Bevölkerung der Erde*, Gotha, 1899, and as regards Turkey in Asia on *Petermann's Mitteilungen* (1896).

Vilayets, Districts, and Countries.	Area in sq. Miles.	Population.	Per sq. Mile.
Turkey in Europe—			
Constantinople (European portion)	1,160	895,500	772
Adrianople	15,000	1,006,500	66
Thrace	16,160	1,902,000	117
Salonica	13,600	1,165,400	85
Selfidje (independent district)	3,050	131,600	44
Monastir	7,650	715,800	94
Kossovo	12,100	961,000	80
Macedonia and Bizas (ancient Servia)	36,400	2,973,800	80
Scutari	4,570	322,000	71
Janina	7,040	648,000	92
Albania	11,610	970,000	83
Total Immediate Provinces in Europe	64,170	5,845,800	91
Turkey in Asia—			
Constantinople (Asiatic portion)	1,590	240,400	151
Archipelago	3,190	325,900	102
Ismidt (Mutessarifut[1])	4,650	222,800	48
Biglia (Mutessarifut[1])	2,890	129,400	45
Brusa	26,390	1,626,900	61
Smyrna	20,450	1,396,500	68
Konia	35,340	1,088,000	31
Adana	15,390	403,400	26
Angora	32,020	892,900	28
Kastamuni	23,110	1,018,900	44
Sivas	32,290	1,086,500	33
Trebizond	12,070	1,047,700	87
Asia Minor	209,380	9,479,300	47
Erzerum	29,590	597,000	20
Mamuret-ul-Aziz	14,550	575,300	39
Bitlis	11,520	398,600	35
Diarbekir	18,060	471,500	26
Van	18,400	430,000	23
Armenia	92,120	2,172,400	27
Aleppo	30,000	995,800	33
Beirut	11,770	533,600	45
Lebanon (Mutessarifut[2])	2,510	399,500	158
Jerusalem (Mutessarifut[2])	8,220	333,000	40
Syria	23,800	955,700	40
Zor (Mutessarifut[1])	32,820	100,000	3
Baghdad	54,480	850,000	15
Mosul	29,200	300,300	10
Bussorah (Basra)	16,470	200,000	12
Syria and Mesopotamia	209,270	4,667,900	22
Hedjaz	96,530	300,000	3
Yemen	77,170	750,000	10
Arabia	173,700	1,050,000	6
Total Turkey in Asia (Immediate Provinces)	684,470	17,669,600	26
African Turkey—			
Tripoli and Barca	397,110	1,000,000	3
Total Turkey in Asia and Africa	1,081,580	18,669,600	18
Grand total Immediate Provinces of Ottoman Empire	1,145,750	24,515,400	21
Under Turkish suzerainty, but not under its immediate government—			
Eastern Rumelia	12,880	998,431	78
Crete	3,330	299,192	88
